MESSRS. VEITCH'S HYACINTHS.—These are now most attractive, consisting, as they do, of hundreds of all the best varieties, the flower-spikes of which, as well as the individual blooms, are unusually large and showy. Associated with them are Tulips, of which there is also a good collection.—M.

FINELY-FLOWERED DENDROBIUM WARDIANUM.—We have a fine plant of this *Dendrobium* in bloom in one of our cool Orchid-houses. It is about 2 ft. in height, and bears upwards of fifty blooms, one of the breaks, 29 in. in length, being furnished with twenty blooms.—LUCOME, PINCE, & Co., Exeter.

MASDEVALLIAS IN PANS.—In Messrs. Veitch's Orchid houses many of these charming plants may be seen growing in pans from 1½ in. to 2 in. deep, the soil and Moss being heaped up on the surface so as to form a mound. On this the plants are placed, and under such conditions they seem to thrive better and flower more freely than when grown in the usual way in pots.—S.

INTERNATIONAL HORTICULTURAL EXHIBITION AT CARLISLE.—At the exhibition of fruits, flowers, and vegetables to be held at Carlisle on the 6th, 7th, and 8th of next September, a sum of £1250 will be offered in prizes. Schedules are now ready, and may be had post free on application to the Secretary, Mr. John Mounsey, Victoria Hall, Lowther Street, Carlisle.

NATIONAL ROSE SOCIETY.—At the first exhibition of this Society which is to take place in St. James' Hall on July 4, upwards of £25, are to be awarded in prizes including three silver cups; a challenge cup of fifty guineas, with the condition that it must be won in three years—thus if it be won by A in 1877, and by B in 1878, only A and B can compete for it in 1879. The subscription is fixed at ten shillings, and for that each member is to receive two five-shilling tickets of admission, entitling the holders to see the Roses for an hour before the Show is open to the public. The Horticultural Club has permitted the Society to use its rooms; and all intending members can address the Secretary of the National Rose Show, 3, Adelphi Terrace, W. C.

Narcissus minor.—When we consider that this beautiful little Daffodil flowers from the middle of February to the end of March—blooming when only 2 in. high, appearing before the Snowdrops are over, mingling with Crocuses of all colours, but more compact, neat, and chaste than most of them—it is surprising that it is not more popular than it appears to be. It will grow in clay, sand, bog, or in almost any soil. It makes charming edgings, and it grows as freely as the common Daffodil.—THOS. WILLIAMS, Ormskirk.

FLOWER MISSIONS.

ONE suggestion I should like to add to the exhaustive paper on this subject given in your number for March 10 (see p. 199), viz., the distribution of tree twigs in winter. *Salix purpurea* and *cornelia* will have catkins in December, and a twig set in a phial will put out roots and leaves, and require not even the water to be changed, but merely filled up if it gets too low. I do not know whether the soft catkins, or, when they drop off, these roots and leaves, give most pleasure. By February the Balsam Poplar suits well to give away, as the fragrant, sticky buds then speedily burst indoors, and give out a wholesome perfume, as well as roots and leaves from every joint. Frequently have I known a headache to pass off by means of a smell of this Poplar's medicinal gum. Lastly, in March there will not be much patience required to wait for the bursting of Horse Chestnut twigs. The great varnished buds "glistening," as Tennyson's "Miller" calls them, visibly crack and open in a fireless room, and the drooping leaves, and even flower cones, appear and gradually straighten themselves out. No winter passes without my having twigs of all sorts of deciduous trees and shrubs in my rooms continually under observation, so interesting do I find them; and the three I have named (Willows, Poplars, and Horse Chestnuts) we distribute with the best effect along with our ordinary winter supplies of Thyme, Rosemary, Sweet Bay, Lavender, and Arbor Vitæ. There is not the slightest necessity for dropping work in winter as far as Nature's stores are concerned, and I have persistently upheld that winter is the most needful time for persevering in introducing a little refreshing smell to those who have such need of it, in a sanitary point of view.

F. J. HOPE.

Wardie Lodge.

Snowdrops.—In addition to the *Galanthi* enumerated by Mr. Burbidge and supplemented by my friend Mr. Elwes, there are two others, viz., *G. latifolius* (a native of the Russian dominions, and figured with *G. Redoutei* in the "Gartenflora"; it has exceedingly broad leaves and small flowers, like those of *G. nivalis*), and the old *G. reflexus* of Haworth, which seems to have been lost since his time; I believe, however, that I have got hold of it. A short time since a *Galanthus* was sent to me to name which I had never seen before; it had very long, narrow petals with a yellow ovary, and the inner segments tipped with this colour instead of green. I at once sent it to Kew, and the reply was that they had never seen it before, and had no specimen like it in the Herbarium, but that it answered generally to the description of the old *G. reflexus* of Haworth. I have long been looking for this plant, and it is with extreme satisfaction that I believe my wishes have at last been realized. The plant was found in an old-fashioned garden in a remote part of the north of England. It probably exists unnoticed in other gardens of a similar character.—H. HARPER CREWE, Drayton-Beauchamp Rectory, Tring.

NOTES AND QUESTIONS—VARIOUS.

Aralias in the South of Ireland.—"W. E. G." will do good work if he succeed in proving the hardiness of any of these stately plants in the South of Ireland; I would suggest his trying *Aralia catalpaefolia*, which resembles a Brodiaeanagian Ivy in its foliage, and forms a stout, low tree.—V.

Azalea Flowers and Black Ants.—Our Azaleas are being injured in a way such as I never saw before; as soon as the flower is open the ants (small black ones) eat a hole through the base, thereby disfiguring the flower. I suppose their object is the honey, as they are busily employed running in and out through the hole all day long. Has any one else observed Azalea flowers attacked in this way?—C. E. PRABSON, Chilwell.

Irregularity of Growth in *Anemone palmata*.—Last autumn two years I planted this, and the following season it flowered and did well until the leaves died off; I anxiously looked for it the next spring, but it did not show above the ground for the entire year, and I felt satisfied that it had perished, but the spot where it grew was not disturbed. To my surprise it came up this winter, and is now in flower. I should state that it was planted on a dry part of the rock garden. Was it want of moisture that prevented its coming up the second season?—D. M., Rochestown, Cork.

Capsicums.—Those who wish to grow Capsicums, either for decorative or other purposes, should now sow a little seed in a pan placed in a warm house. When up the plants should be grown on in a pit or frame where a moist atmosphere is maintained, and if placed close to the glass and abundance of water be given at the roots, in ten or twelve weeks they will make bushy plants about 18 in. in height, loaded with bright golden or scarlet fruits, each as large as a Walnut. When skilfully grouped as regards colour, they are very attractive, a condition in which they will last for several months.—S.

Early Spring Cabbages.—We are now cutting from a south border useful little spring Cabbages, which at no season of the year are more acceptable than now. We plant them 1 ft. apart each way, and they are off the ground in time to allow it to be occupied by French Beans or some similar crop.—J. GROOM, Henham.

LITTLE VASES OF COMMON FLOWERS.

EXTENSIVE arrangements of choice flowers and foliage, however desirable they may be in some few cases, especially where rare Orchids, forced flowers, and delicate Ferns are obtainable at all seasons, are completely out of the reach of many of those who, nevertheless, appreciate the every-day enjoyment of flowers in their dwellings. Doubtless our floral exhibitions have fostered the idea amongst many that it is impossible to form tasteful indoor arrangements without a profusion of choice tropical flowers and Ferns, but I am sure I derive quite as much real enjoyment from a handful of rich crimson-brown Wallflowers and golden Narcissi, or from a few freshly-picked Violets and Snowdrops in a saucer of living Moss, as I could possibly do from the most costly tropical flowers. The annexed illustration represents a few common Cyclamens and other hardy flowers, sprays of *Bambusa Fortunei variegata*, and the crimson berries of the Bittersweet *Solanum*, arranged in a tall Bohemian wineglass half filled with spring water, and the remaining half with fresh living Hypnum Moss, the fresh greenness of which contrasts well with the flowers and berries, and at the same time tones down the somewhat too pronounced silvery sparkle of the glass. B.

Preservation of Cut Flowers.—When possible, flowers should always be cut from plants that are well hardened off, avoiding as much as possible those grown in stove-heat. In Ferns, well-matured fronds only should be cut, as young ones are certain to shrivel up in a few hours after being used, and consequently spoil the effect of any decoration in which they may be employed. In cutting them a sharp knife should always be used in preference to scissors, which crush and close up the minute tubes or veins through which the moisture is drawn up, while, if cut with a knife, they remain open. If required to be kept for only a day or two, the flowers should be cut early in the morning, each variety tied into bunches by itself, and then placed in earthenware jars or wide glasses, filled with cold water, which should be put in some dark, cool place till required. A cool, dark cupboard in a cellar is an excellent place to keep them, sprinkling the shelves and sides first, and keeping the whole place as moist as possible. Many flowers, such as Rose-buds, Gardenias, Eucharis, &c., keep better if cut and put in water, or laid on damp Moss, than if left growing on the plant. Others, like Heliotropes, Tuberozes, &c., spoil much more rapidly if wet overhead, though the greater variety of flowers used are all the better for a good sprinkling before being put away. It is an excellent plan with many of the finer Ferns, such as Maiden-hair, to leave them in water for an hour or so before using them; they thus get thoroughly saturated, and will keep a whole day without wilting. When loose flowers are arranged in vases or dishes, it will be found a good plan to lift them out and place them in a basin of cold water in a cool, close place; then, in the morning, cut a short piece off the end of each, in a slanting direction, to keep the ends of the tubes open, arranging them again in fresh, cold water. Vases of flowers can be kept fresh for a week at a time if they are thus treated. Bonquets and baskets of flowers, such as come from the florists, if well sprinkled every evening and placed in a cool, damp closet, as just described, will keep fresh a much longer time than if allowed to remain in a warm, airy room.—“American Paper.”

THE INDOOR GARDEN.

CULTURE OF ACHIMENES.

THERE are few plants more beautiful or useful, or that afford such a variety of form and colour as Achimenes, ranging, as they do, from the most brilliant scarlet to white and blue, and many other shades too numerous to mention; while, as to size and form there is just as much diversity, some having long tube-shaped flowers (as in *A. picta*), and others flat and large as a crown piece (as best shown in the magnificent variety known as *A. longiflora major*), and of the most lovely shade of blue. In *A. coccinea* we have one of the most minute-flowering species of the whole family, but its deficiency in size is compensated for by the extraordinary profusion of its blooms and their brilliancy of colour, which is of a dazzling scarlet. Although one of the oldest it is still one of the best, and ought to be in every collection on account of its general usefulness and the striking contrast it affords when associated with other plants; besides which, it may be had in good condition much later in the autumn than most of the hybrid varieties, unless subjected to more heat than is necessary. *A. picta* not only affords very beautiful tube-shaped flowers, but has likewise ornamental leaves, besides the additional merit of blooming in the winter if subjected to stove-heat, and is then a fit companion for the Gesneras, to some of which it bears a close resemblance.

The value of Achimenes to amateurs and others having only a limited amount of plant room, and who are nevertheless desirous of making a rich floral display during the summer months is, that they die down and require no care in the winter beyond stowing them safely away out of reach of frost, wet, or vermin, such as rats and mice, which feast on the tubers. Another merit of Achimenes is, that they require no expensive stove-house or similar structure in which to grow them, as they will do equally well, indeed better, in any hotbed, pit, or frame, such as is usually made up for Cucumbers, Melons, &c.; while, later on, they may be grown without artificial heat, if advantage be taken of

sunshiny days to shut them up early and secure the requisite warmth in that way. Beautiful as they are when displayed in pots in window recesses in rooms, or for the embellishment of greenhouses, they are even more so when suspended in baskets, for which work their habit renders them peculiarly adapted, as they droop over in the most graceful manner possible, and show off the flowers with which they are laden to the greatest advantage. In pots they require stakes to support them, but in baskets few are necessary, as they generally present a more effective appearance, trailing naturally over the sides; and the less formal they grow the better they look. For whichever purpose they are required, it is a great saving of valuable space to start a sufficient quantity of each kind in separate pans or pots, and afterwards to divide and transfer them to the positions in which they are intended to flower.

Those who are not so fortunate as to possess a few varieties of these very beautiful flowers should lose no time in getting

A Vase of Common Flowers.

the tubers and starting them at once in any close, warm place, where the soil in which they are planted will not become dry too quickly. A hundred tubers will be sufficient for ten 6-in. pots, which are the best and most useful sizes for room decoration or ordinary purposes; but if larger be required, a few more plants will be necessary to fill them. They may be started into growth in any small pot or pan in finely-sifted leaf-soil and sand, in which they should be allowed to remain till they get 1 in. or so high, when they may be taken out and carefully separated for potting or putting in baskets. Owing to the great quantity of water they require when growing, the pots must be well drained, which should be done by filling them up to a third of their depth. The next operation is to cover the potsherds with a few half-decomposed leaves, rough fibry peat, Moss, or any similar material, in order to prevent the soil blocking them up. The best compost for Achimenes is a mixture of rough fibry peat and loam or leaf-soil, and the latter in the proportion of one of loam to two of peat or rotten leaves, in either of which the plants greatly delight, adding just sufficient sand to keep all open and porous. In potting, they should be placed equidistant, and the roots covered loosely, but not in sufficient quantity to fill the pot, as they make better progress if afforded a top-dressing later on when they get into growth and begin to form fibres around their stems, a little fresh soil at that period becoming of the greatest assistance to them. After the potting has taken place, they should again be placed where they can enjoy a warm temperature ranging anywhere between 55° and 65°, with plenty of moisture in the atmosphere, and in such a position as to be near the glass exposed to the light to keep them from drawing. The degree of heat above-named is the minimum they will endure or ought to have thus early, but if more can be afforded with a proportionate amount of humidity, they will grow all the faster and come earlier into bloom.

The baskets in which I grow them are basin-shaped, made of galvanized iron wire run round a frame made of the same, a trifle larger in size, and bound tightly together, which any handy man can do. These are then lined with rough Moss and filled up with the same kind of soil as recommended for the pots, and the plants afterwards ranged regularly around the sides by making holes with the finger between the wires in which to insert the roots, after which they should be hung up in any warm house and kept well watered and syringed till they begin to show bloom. By starting some now and others at intervals of a month or so till the end of June or middle of July, a constant succession may be maintained till quite late in the autumn and far on through the winter, by adding *A. picta* to the collection. Although they will endure all the sun we get up to the end of April, they will not do so afterwards, as they are naturally shade-loving plants; and it is therefore necessary to throw a mat over them to screen them for an hour or two in the hottest part of the day during the height of summer, or whenever the sun's rays are full upon the glass. At that season any cold frame, having a few leaves in which to plunge them, or a firm bed of ashes on which to set them, answers admirably, as in such a position they can be treated more in accordance with their requirements than they could be elsewhere among other plants. A heavy syringing overhead both morning and afternoon, or a gentle bedewing through the rose of a watering-pot during dry weather so as to thoroughly moisten their foliage and the material in which they are plunged or on which they are placed, is the course of treatment to pursue while they are growing; and to assist them in their development the house should be closed about three o'clock in the day in order to take advantage of sun-heat. The necessary staking and tying should be done before they become too advanced, or the blooms get damaged during the operation, besides which their fragile stems are not sufficiently stiff and strong to remain erect after they have attained a height of 6 in. or more. The neatest and best stakes are the long, twiggy prunings from Privet hedges or bushes, which should be cut at once and tied tightly up in bundles and laid by till required. They then become hard and almost as stiff as wire, and being nearly of the same colour as the stems of the Achimenes they are scarcely observable, thereby removing to a great extent the objectionable appearance which stakes

among pot plants generally present, and as the plants require one to each main stem, deal sticks would be much too obtrusive, and quite spoil their attraction. Although Achimenes require a moderate amount of heat and a moist atmosphere while growing, they will endure any ordinary greenhouse temperature during the summer, and if kept well watered they will last a long time in perfection.

Many growers of these charming flowers commit the mistake of allowing them to die down, or rather force them to do so by withholding water directly they have ceased blooming; and when that is the case, the tubers they form in such abundance under proper treatment are only found in the most meagre quantity, of small size, and imperfectly matured, few of which, from being in such an unripe condition, are able to survive the winter. The proper course as they go out of bloom is to place them in any pit or frame where they can be easily watered and receive a syringing occasionally, so as to keep their foliage fresh and green as long as possible, under which treatment they will develop large, plump tubers which it will be no difficulty to keep in a sound, healthy condition. After the tops have died away naturally, they should be trimmed off and removed, and the pots stored away on shelves in a shed, cellar, the back of a greenhouse, or any other position where they can be kept dry, but on no account should the tubers be picked out of the soil, as in no other way do they winter so securely and well as if left embedded where they have grown. The rapid way they increase by forming so many tubers when properly treated will always afford sufficient stock after the first year; nevertheless, in the case of new or choice varieties, it is often desirable to resort to other modes of propagation. Cuttings made in the ordinary way from the tips of the young growth when the plants have got about 6-in. high root readily if placed in sandy soil where they can be kept in a close, warm situation, such as any hotbed, frame, or under a hand-light in any forcing-house or pit, and in such a position as to be shaded from the sun. Plants so obtained will flower equally well as those raised from tubers, and any from which cuttings are taken branch out freely again, and are none the worse for being robbed of their heads. The following are a few of the best kinds:—Mauve Queen, longiflora alba, l. a. major, Ambrose Versehaeffelt, Carl Woolfarth, Stella, Parsons, Loveliness, Meteor, Dazzle, Pink Perfection, and Williams. S. J.

FRANCISCEAS AND THEIR CULTURE.

FRANCISCEAS rank amongst the finest and most distinct of flowering stove plants; they vary considerably in size, from the small, moderately compact, upright-habited *F. Hopeana*, to the broad Laurel-leaved *F. confertiflora*, which, when well grown, attains a height of 5 ft., and 3 ft. or 4 ft. in diameter; its ample dark-green glossy leaves form a perfect background to its large purple flowers, deep in colour when first opened, but, like those of most of the other species, turning gradually paler as they get older, until they assume almost a white shade. *F. confertiflora* is undoubtedly the finest representative of the genus, taking all its properties into account, although it is eclipsed in size by the largest form of *F. calycina*, called *F. calycina major*; but neither this nor the smaller form retains its leaves so well as *F. confertiflora*, nor do they grow so freely. The beauty of the flowers of most of the species is much increased by the white ring round the mouth of the tube, which is most conspicuous when they first open, contrasting well with the intense colour of the newly expanded blossoms. Another desirable property which they possess is that, in addition to opening their flowers in succession, a circumstance which prolongs their blooming over a considerable period, the time of their flowering may be so regulated as to have a continuance for several months, extending from early spring until the summer is far advanced, which much increases their value, either for exhibition purposes or for general decoration. As conservatory plants they are invaluable, as from their not requiring a high temperature, especially when flowering, they will stand that of an ordinary greenhouse. There is one thing in which several of the species, more particularly *F. confertiflora*, differ from most other plants, and that is, that, although they require a moderate heat to grow

them well, they will open their flowers freely and much finer in colour in a cool house and when closely shaded, than they do in heat; this is the more remarkable, as it is completely at variance with the requirements of the greater number of plants. There are one or two matters peculiar to their cultivation of which it is essential not to lose sight. First, at no season, either when making their growth, or even when it is completed and the wood and leaves are fully matured, can they bear the effects of the direct action of the sun, or the deep glossy green of their leaves will be quickly converted into a dingy brown, sickly hue; and, when in flower, the colour of the blooms becomes bleached in a day or two if the sun be allowed to shine upon them. The second and equally important point is that they should at all times be kept free from insects—especially that worst of all pests, mealy bug, which, if present at all, is sure to get the plants into bad condition; for not only do the flower-buds get injured by the operation of cleaning and fall off, but the leaves also suffer. Other insects will live upon *Francisneas*, but none else are so injurious.

All *Francisneas* are easily propagated by means of cuttings made of the half-ripened wood, which may generally be obtained by the end of April from plants that have made early growths in the stove. Bits of the leading shoots about 4 in. or 5 in. in length, inserted in small pots filled with sand, placed in a temperature of 70°, covered with propagating glasses and shaded, will root in a few weeks, after which the glasses should be removed; put them where they will receive plenty of light, but shaded from the sun. As soon as the cuttings have filled their little pots with roots, they should be moved into others 4 in. or 5 in. in diameter. They will all grow in either peat or loam, or a mixture of both; but, like most evergreen plants with large leaves, they grow freest in peat, which gives the deep green colour so desirable. In peat they will also make stronger shoots, which, in the case of *Francisneas*, always produce the most flowers. The peat should be of good quality, containing plenty of undecomposed vegetable fibre. For the first potting, break the soil into bits the size of Acorns, and add one-sixth of clean sand; drain the pots sufficiently, and press the soil moderately firm; pinch out the points, at the same time bending the leading shoot down in a horizontal position, which will cause more of the latent back buds to break than would otherwise happen if the principal shoot were allowed to remain in an upright position. They will grow in an intermediate temperature, but make more progress if kept through the summer at 70° during the night, with 10° or 15° higher in the daytime. Do not allow the shading to remain over them when the sun is not out; for, although as I have already stated, they cannot bear direct sunshine, if grown with insufficient light the leaves will be soft and deficient in substance, light being indispensable to vigorous health. Give air in the early part of the day, but close sufficiently soon to cause the temperature to rise for an hour or two up to 90°, syringing overhead at the same time. *Francisneas* are free-rooting subjects, and by the middle of July they will require another shift, moving them into pots 3 in. larger, at the same time pinching out the points of the shoots, and tying them out, so as to keep the plants open; in other respects treat them as before, supplying them with plenty of water at the roots. By the beginning of September they should have more air, decreasing the shading, but not dispensing with it altogether until the sun has less power. Though the different species will bear through the winter a temperature of from 45° to 50°, in the early stages of their growth it will be advisable to keep them warmer, as the object will be to get them on in regard to size. A temperature of 55° will be a suitable heat for them until the end of February, when it may be raised 5°. In March again give them a shift into pots from 4 in. to 6 in. larger, according to the kinds; the smaller varieties, such as *F. Hopeana*, *F. eximia*, and *F. Lindenii*, not requiring near so much room as the stronger-growing *F. confertiflora* and *F. calycina*. A 12-in. or 13-in. pot is large enough for a full grown specimen of *F. Hopeana*, which is the smallest; whereas *F. confertiflora*, when at its full size, will need one 18 in. or 20 in. in diameter. In other respects, as to soil, temperature, shade, and moisture, similar treatment will answer for all. Again pinch out the points of the shoots, tying them out, so as to furnish the

base of the plants down to the rim of the pot. As the season advances, increase the temperature as before, giving shade, air, and moisture as in the preceding summer. By the middle of June they will again require stopping, after which the treatment will be of a routine description. They will make good decorative plants the coming spring, and to afford a succession, there will need to be a difference made in the time during which some are allowed to remain in heat after the last stopping. As soon as the shoots have attained their full length, which may be looked for in September, a portion of the plants ought to be at once moved to a cool house, where they should have a moderate amount of air, but slightly shaded when the sun is bright, as even at that time of the year, when its power is fast waning, the leaves will be much better not exposed to its full influence. The remaining portion of the plants may be allowed to remain in heat some weeks longer until the flower-buds are quite visible, when they also should be moved to cooler quarters, giving them less water; but at no time must they be kept so dry as many things require to be, or the large-leaved ones will be found to flag when air is given them, which has the effect of injuring the foliage. They should be kept through the winter at from 45° to 50°. A lower temperature than this they do not like, and anything above it will bring them into flower too early in the spring. The plants that were allowed to stay the longest in heat until their bloom-buds were formed will go on increasing them in size through the winter, flowering the earliest, the time of which is easily regulated by giving them more or less heat. Those that were first taken out of heat will make little perceptible progress until the days get considerably longer in spring, when the increased solar warmth will cause the flowers to set, which will keep gradually but slowly increasing in size until they expand. Plants thus managed may be kept by placing them in a north house to bloom in July, in all cases shading when the sun is bright, even as early as the beginning of March. In their ability thus to set flowers in a lower temperature than that in which they have grown, they differ from most plants. After flowering they should have their shoots cut back, so as to keep them bushy. If not shortened in each season before they are started into growth, they would soon get into a loose, straggling condition. Again place them in heat; although they do not require it, still they will bear as high a temperature whilst growing as most plants. As soon as they have broken into growth they will require re-potting, giving them a shift proportionate to the condition of the plants and the size and strength of the species grown. From this time forward they will not need much, if any, stopping, except in the case of such as have bloomed early in the spring, simply managing them in other respects as in the past season. If kept free from insects and fairly treated, they will last for a number of years, assisting them during the growing season with a regular supply of manure-water. When they get into pots as large as it is desirable to put them, and the soil in these is exhausted, they may be headed back to half their size, and when they have broken, turned out of the pots and half the old soil removed, re-potting them in smaller pots. Thus treated, they can be furnished with strong-flowering shoots, even superior to what they possessed in the early stages of their existence.

The under-mentioned sorts are all deserving of cultivation:

F. CONFERTIFLORA.—A free, dense-growing species, one of the finest exhibition plants in existence, and suitable for conservatory decoration, the deep purple colour harmonising well with that of almost any other flower. It is from Brazil. There is a form of this plant with variegated leaves, the blooms of which do not differ from those of the species. It is not so free a grower.

F. CALYCINA MAJOR.—This is a large-flowering, strong-wooded kind, with ample leaves and very large, deep-coloured flowers, but the latter are not produced in such numbers as in the case of *F. confertiflora*; nevertheless, it is a splendid sort. It comes from Brazil.

F. EXIMIA.—A somewhat erect-habited plant, of moderate growth, producing large heads of purple flowers. It is a native of Brazil.

F. LINDENII.—This is a smallish-growing species, with dull coloured leaves, and very bright purple flowers. A most

desirable plant for general decorative purposes, not nearly so well known or so extensively grown as it deserves. It also comes from Brazil.

F. HOPEANA (UNIFLORA).—A small-growing species, that produces its flowers freely from short spurs up the branches as well as from the points of the shoots and axils of the leaves. The flowers are pale purple or lilac, changing to white. It is from Brazil.

Thrips, red spider, and green fly will sometimes make their appearance upon *Franeisceas*: but, from the repeated use of the syringe during the growing season, they do not often become very troublesome. Copious syringing and fumigation will be found sufficient to destroy these pests. Should mealy bug and scale appear, they must have no quarter, or they will, if allowed to get numerous, reduce the plants to a condition that precludes the possibility of their flowering satisfactorily. They must be diligently sought after during the growing season, using the sponge and a soft brush for their destruction, and when at rest repeated washings with insecticide by syringing and dipping. T. BAINES.

Primula cortusoides amœna for Forcing.—This hardy *Primula*, though seldom seen growing in pots, forms a useful plant treated in that way for the decoration of the conservatory at this season of the year. Plants of it taken up from the open ground in autumn, and potted and introduced to gentle heat, may be had in bloom from January onwards. In this way they are treated in Rollisson's nursery at Tooting, where numbers of plants may now be seen laden with large umbels of deep rose-coloured flowers, which, when associated with other plants, have a fine effect. They are also much more useful for cut bloom than any of the single-flowering Chinese varieties.—S.

Large-flowering Pelargoniums.—Some whose deficient glass accommodation necessitates crowding plants together, are just now experiencing some trouble with their show *Pelargoniums* potted into their blooming pots last autumn. Owing to the mild winter they have kept moving onwards, and they are now progressing too rapidly, seeing that they will not be wanted till May and June. A few of the most forward of them may be allowed to flower as soon as they like, but others should be pinched back slightly, an operation which, while it tends to retard the plants, will also make them more bushy in habit. As regards cleanliness, they will now require some attention, being plants prone to be infested with green fly, which, however, may be got rid of by means of fumigation with Tobacco. Some houses are, however, so badly constructed that the smoke passes off without doing its work. In that case dissolve some soft soap in hot water, and add some sulphur, and when it is cool enough for use dip the heads of the plants in the mixture, giving the leaves a final rub with a piece of sponge. This is an effectual remedy, and one which the plants appear to enjoy.—D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

A Noble Shrub for the Conservatory.—*Aralia catalpaefolia* planted out forms a shrub or low tree of very remarkable beauty, stately in habit, and with massive foliage of fine form. The leaves are very much like gigantic Ivy leaves; sometimes they are quite 1 ft. long.—V.

Acacia coccinea.—This is not the day for *Acacias*, and many of the kinds—the better kinds even—are now seldom seen, but there is one variety that should not be lost sight of, and that is *A. coccinea*. It is valuable for two reasons, its colour, and the fact that it blooms almost all the year round.—T.

Winter Vase Plants.—Few plants are more useful for this purpose than *Common Box* in the form of good-sized specimens. It lifts with a good mass of roots, suffers less from removal than most plants, and, if carefully replanted in the reserve garden, it will keep serviceable for many years.—J. G.

Rubus roseifolius.—This interesting Bramble is useful in the cool house in winter, where it produces its flowers freely.—T.

Phajus graudifolius.—This well-known Orchid forms at this season a conspicuous ornament in plant stoves, in which in addition to its fine spikes of flower, it also possesses a profusion of striking foliage. Some old plants of it now in bloom here are furnished with from twelve to fifteen spikes of flower, and well repay any little labour which they may have entailed.—J. GROOM, *Henham*.

The Lemon Grass (*Andropogon schenanthus*).—This beautiful sweet-scented Grass, with its long, narrow, pale green, wavy leaves, light midrib, and white-powdered stem, is a fine plant for warm greenhouses or stoves. When the leaves are rubbed or slightly bruised, they emit an odour like that of the Lemon-scented Verbena (*Aloysia citrodora*); the leaves are from 3 to 4 ft. long when grown in a 32-sized pot.—R. H. B.

THE FLOWER GARDEN.

GARDEN VARIETIES OF POLYANTHUS.

AMONGST old-fashioned plants, the garden forms of *Polyanthus* occupy perhaps the highest place; in all old gardens they were ever held in the highest esteem, and they are yet in many places the chief denizens of the spring flower garden. Cultivators now-a-days find that the *Polyanthus* has expanded into a large family, and, if desirous to make their cultivation a speciality, are perhaps rather troubled to know which section is most worthy of their attention. Florists have preserved tenaciously the memory of the beautifully marked, or rather laced, forms of the old exhibition kinds; indeed, the memory of these has been better preserved than the plants themselves, as few things are now so difficult to obtain as stock of any of the fine old show varieties. The exigencies of business have of late brought up a number of named varieties, but these, alas! are all of the most valueless kind, and have little or nothing in common with their older compeers. If something more than the memory of the Gold-laced *Polyanthus* of forty years ago is to be preserved, we must take to the raising of new kinds in earnest from the very best stocks, and then perchance a future generation may be enabled to gaze upon forms with which few of the present are familiar. In the finer, more varied, and altogether more decorative section of the *Polyanthus* that has of late grown up under the heading of Fancy or Self kinds, we, however, get forms that are of the greatest value for garden decoration, used either for massing as border plants or for pot culture, some of the best kinds being as well worthy of culture under glass as any hardy plant can be. The breaking up of these into colours for bedding purposes is an undoubted gain to the spring-flower gardener, as these kinds bloom earlier than the Gold-laced forms, and are at their best early in April if the season be at all favourable. Self in white, sulphur, yellow, red, and crimson, are common, but intermediate hues of lilac, magenta, and purple are not so abundant. These, however, are hues that never have been common to the *Polyanthus*. Some of the Self kinds are absolutely perfect in form and in refinement, but this latter quality is best seen when the plants are grown under glass, treatment which is indispensable if grown for exhibition. Perhaps the greatest need is a rich golden-yellow of perfect form; there are plenty having this hue that make effective bedders, but none that come up to the florist's ideal of a perfect flower. In the London market gardens there is grown a strain of Self-coloured flowers that partake largely of the Gold-laced section in habit, but that have larger blooms, and entirely lack the lacing so peculiar to that section. These have very dark hues (some almost black), with, in the best, clearly defined lemon centres; and as a section standing out from others, or looked at as consisting of dark Self flowers, they are extremely rich and beautiful. A few of these picked out from a large bed last year furnished a little seed, and by continuous and careful selection for a few years it is possible that some really fine exhibition dark Selfs may be got out of them. It is a strain that, like the Blood-red Wallflower, can only be met with good around London.

Allied to the Fancy section, and, indeed, growing out of it, are the semi-double forms, that are sometimes called *Primula veris duplex*, but which in reality are hose-in-hose forms of the Fancy *Polyanthus*. Hitherto it has been found that the majority of these had flower-stalks that were weak and spindly and therefore incapable of holding the large heads of double blossoms which they bore erect. Of course this habit has militated against their extensive cultivation, even though many of them were very beautiful. Careful selection, however, is gradually curing this defect. A few exhibit stout, erect stems that equal the best of other kinds, and perchance, with care, these may ultimately lead to the production of a fine double strain. One variety of the Fancy class has tall stems, bearing flowers of great size and fine form, a large, bold orange eye, with a broad reddish-crimson margin, and will doubtless prove the parent of many good kinds in the future. I have this year flowered for the first time some pure white and bright sulphur in colour, and several not yet in bloom promise to add variety allied to a good habit. Seedling plants that will produce double flowers show this form at an early stage,

as the flower-buds are larger and show the coloured calyx ere the flowers are expanded.

Whilst the semi-double forms of the Fancy breed are assumed to be allied to *Primula veris*, most if not all of the old garden Hose-in-hose are allied to *Primula elatior*. Perhaps one of the best known is the old white kind, a pleasing and distinct form, but not now common. It is sometimes met with in old gardens, and I have recently seen flowers of it sent from a garden in Cornwall. A large yellow Hose-in-hose, under the name of Golden Gem, received a certificate last year at South Kensington; it is a very effective border or bedding variety, and has evidently a good robust habit. From Ireland has come yet another yellow double form, the flowers of which are rather smaller than those of the other, but of a deeper hue; this is known as Golden Bedder. It is very effective as a decorative plant, and well worthy its designation. It is noteworthy that both of these are what are technically called pin-eyed, but I have seen flowers of a rich yellow form that have thrum-eyes. There is one distinguishing characteristic of these *elatior* Hose-in-hose, viz., they invariably open both flowers at once, whilst in the *veris* section the upper flower is usually expanded some time before the lower one. The Jack-in-the-Green forms of the Polyanthus are more curious than valuable; indeed, the flowers are generally small, and are too much overshadowed by the large, green calyx, which gives them their name. Of these there are various hues and forms; in some the flowers are white, in others yellow, in others red, and so on, but relatively they are so unattractive that those who have a fancy for curious plants only care to grow them.

Perhaps the smallest section of the Polyanthus is found in the double kinds, of which I know at present only two—a reddish-crimson, named Rex Theodore, and one recently imported from Lyons under the name of *P. violacea fl.-pl.* Rex Theodore is a true Polyanthus, but its flowers are much inferior to the fine double blooms of the *Primula acualis*. *Primula violacea*, on the other hand, seems more nearly allied to the double Primrose in habit, but the flowers are borne on short stalks, and are in colour purplish-mauve; this is at once distinct, and a real acquisition. Lastly, there comes in the garden Polyanthus a sort of connecting link with the Primrose, and although designated a Hybrid Primrose, is truly Polyanthus in habit. The distinction is founded on the fact that these throw up first an abundance of flowers on single stalks, exactly as the Primrose does, and then follow scapes of flowers on stiff footstalks, so that the plant begins a Primrose and ends a Polyanthus. That capital bedding kind, Queen

of Yellows, affords a good illustration of this habit; but the gem of all this section is found in Prince Charming, a really lovely variety, the flowers of which have a ground colour of rosy-peach edged with pure white, and a clear lemon eye. Although this section is not a large one, yet it consists of sufficient plants to show that it is necessary for distinction. I have thus introduced all the garden forms of the Polyanthus with which I am familiar—certainly enough to show that they constitute a large and varied family, and when to these are added the double and single forms of the Common Primrose (*Primula acanlis*), it becomes, I think, quite evident that sufficient variety may be found to suit the tastes of any ordinary grower.

A. D.

Bedfont.

Great Bulrush (*Typha latifolia*).

The Crimean Snowdrop (*Galanthus plicatus*).—This is indeed a noble Snowdrop, and one which deserves a word or two of commendation. We have a dozen or more small round beds (encircling the roots of standard Roses placed on the turf at considerable distances apart), which have been filled with this harbinger of spring for several seasons past, and the effect has been pleasing in the extreme. The additional stature of the plants and the size of the flowers render them far superior to the commoner Snowdrops for such positions, and if the effect of such an arrangement could be added to, I would suggest an edging of the Siberian Squill. It is to be hoped that the Crimean Snowdrop will continue single, and that no effort will be made by crossing, &c., to render it double. A double Snowdrop is, to my mind, a Snowdrop spoilt, robbed of full half of its natural grace and beauty. Unfortunately in the Eastern Counties nearly all the Snowdrops are infested with the doubling mania; even those growing wild in the woods are nearly all double, and I have the greatest difficulty to preserve a few patches of the single kind here from degenerating into double flowers. The

doubles are carefully eradicated every year, but hardly a season passes that numbers do not make their appearance. Hitherto the Crimean Snowdrop has shown no tendency in this direction.—D. T. FISH.

The Typhas.—Happily the taste for seeing beauty in common things seems increasing among us, and, such being the case, a few words in favour of these stately native water plants will not be amiss. They are well worthy a place in any pond or stream margin. When not over numerous in such a position they have a very good effect. The writer has grown three kinds—*T. latifolia*, *T. intermedia*, and *T. angustifolia*—and a tuft of each looked very well in a pond; but none of them should be allowed to spread much. They associate well with the large Water Dock, the Flowering Rush, the showy Loosestrife, and the Hairy Willow Herb, which all grow well in a foot or so of water.—V.

HARDY FLOWERS IN LONDON GARDENS.

THE majority of hardy flowers of which mention has been made during the past few weeks still retain an attractive appearance, and the occasional gleams of bright sunshine which we have experienced have been the means of bringing out a few additional kinds, among which may be mentioned the Crown Imperial (*Fritillaria imperialis*), plants of which are opening numerous flower-buds in warm situations in the Tottenham nurseries; strong plants, too, of *Corydalis bulbosa* are furnished profusely with reddish-purple blossoms. The long tubular-shaped purple and blue flowers of *Pulmonaria officinalis* are now very pretty, mounted on gracefully-drooping stems, and large beds of sundry varieties of the Grape Hyacinth (*Muscari botryoides*) are producing pretty spikes of blue flowers. *Sisyrinchium grandiflorum album* is producing numerous pure white blossoms in protected positions in the Wellington Nursery, where the Pasque-flower (*Anemone Pulsatilla*), growing in the form of large clumps, is pushing up hundreds of large, drooping purple blossoms. The double yellow flowers of the Marsh Marigold (*Caltha palustris fl.-pl.*) are also now very showy, peeping from among dense masses of Ivy-green leaves. The little Alpines (*Androsace carnea* and *Draba lasiocarpa*) are just now coming into bloom; and the common blue and white Hyacinths are throwing up well-furnished flower-spikes in warm places. The double Roman and the Paper-white Narcissi are just now at their best, and are being brought in a cut state to market in large quantities. Perhaps the most showy of all the hardy bulbous plants now in bloom are the various forms of Daffodils, the most distinct of which are *Narcissus minor*, *N. nanus*, and the smallest of all, *N. minimus*, the flowers of which are scarcely above the surface of the soil; *N. bicolor* is just opening its blossoms, and its allies, *N. Horsfieldi* and *N. Empress*, a seedling from the last, raised by the late Mr. W. Backhouse, of St. John's, Walsingham, are fast approaching the flowering stage, as is also that finest of all the Daffodils, *N. maximus*, the flowers of which are of a deep golden colour, and fully 4 in. in diameter when fully expanded; *N. montanus* is likewise bearing its nodding white flowers, as also are the golden-flowered forms of *N. odoratus* and the seedling varieties of *N. Tazetta*. A large batch of new seedling Narcissi is just beginning to open their flowers in Mr. Barr's bulb grounds at Tooting, and among these we noted some distinct variations, both as regards form and colour. Many of them are hybrids, the result of crosses effected between *N. Pseudo-Narcissus*, *N. incomparabilis*, *N. Macleai*, *N. (montanus) poculiformis*, and *N. poeticus*, and some of them are well worth having and preserving as distinct and effective garden plants. S. B.

MATCHING COLOURS IN FLOWER GARDENS.

MANY who can grow flower garden plants to perfection signally fail in making a display in accordance with good taste. For this many reasons exist, notably an unacquaintance with the laws relating to colour, and sometimes a want of acuteness in distinguishing between the different colours. What are called primary colours consist of red, yellow, and blue, and of these all others are simply combinations. Thus yellow and red make orange, yellow and blue make green, and blue and red make purple, and so on. Now, as the primary and secondary colours should be arranged alternately, a secondary should always be opposed to a primary. For instance, green should be exactly opposite red, and purple opposite yellow. Now, green is the complement of red, and purple is that of yellow. This may be proved in another way. Take a sheet of clean white paper and make a blotch of red in the centre of it the size of a penny. Gaze steadily at the red blotch for a few seconds, and then suddenly shift your gaze to a clean sheet with nothing on it, and a disc of green will appear. That is why we call green the complement of red, and green and red always look well in juxtaposition, whether in a flower garden or elsewhere. This is one reason why the old Tom Thumb Pelargonium held favour so long. Its leaves were a beautiful green, and one fault in many of our scarlet bedding plants is that their leaves are not a beautiful green, but often spoiled by dark zones. I have little doubt that the rising popularity of bedding Violas, in one sense at least, is owing to the fact that one class consists of purples and the other of yellows—purple being just the complement of yellow. I have a narrow border which was planted last year with one row of Golden Gem Viola next the gravel,

and behind that one of The Tory, and this simple arrangement was admired by every one who saw it. The colours were complimentary and true to Nature; it was, therefore, consistent that they should please. Blue and white, either in lines or mixed, always look well. White, however, is not a colour, and will bear placing anywhere. The same may be said of black, though it cannot be so appropriately planted anywhere. However, we have no real blacks either in flowers or in foliage. The nearest approach to black which I have seen is in Pansy Bismarck, and that is not suited for bedding. The Perilla and Dell's Beet are bronzes, and have to be complimented according to the shade which they present. In the planting of single beds, people who understand the laws relating to colour often plant, say, three colours, a central mass, a belt round that, and an edging. I have frequently seen the mistake committed of placing a strong colour in the centre; the band a complimentary colour, and the edging in harmony with the band. Now, it may seem that nothing can well be urged against such an arrangement, as such a bed is planted in accordance with the laws of colour. This is to some extent true, but such a bed will always be inferior to one planted on exactly opposite principles. In such an arrangement the centre and the band encircling it monopolise the vision, and the bed seems much less than it really is; the edging or boundary line is vague and indistinct, and it requires an effort to comprehend the whole. Planted the other way, the effect is exactly the reverse. When the centre beds of a design are arranged in harmony with each other, and the outer beds consist of complimentary colours, the central effect is agreeably subdued, while the outlines of the design stand out in bold relief, and with a distinctness not otherwise attainable. In the case of a single bed the effect is similar. Many, however, plant yearly with only one end in view—the filling of the beds, and no matter how great the medley, if the plants grow well they are content.—ALEXANDER HONEYMAN, *Hope Park*.

Substitute for *Myosotis dissitiflora*.—A short time ago a notice of this plant appeared in THE GARDEN, wherein mention was made of the unsatisfactory character of this Forget-me-not for forcing; and such is my own experience. Allow me, therefore, to point out a substitute in the old *Omphalodes verna*, in my opinion a handsomer plant than the *Myosotis*, seeing that it has not only beautiful flowers, but good foliage, a great advantage to a mass of colour, however lovely, in early spring. The plant in question is easily managed. Pull some old specimens of it to pieces, and take care of them through the summer, pinching well in all runners, to throw out which the plant has a tendency; select the strongest plants—say in October, plant them as you would Lilies of the Valley—from five to seven crowns in a pot; winter them in a cold frame, and introduce them into gentle heat (they will need very little) as wanted. When in flower, keep the runners well pinched in, and the plants will be better the older they grow.—THOMAS WILLIAMS, *Ormskirk*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

***Leucojum carpaticum*.**—This pretty Snowflake is now in bloom. It flowers a month or six weeks later than *L. vernum*, and, unlike that species, begins to expand its blossoms when the stalk and the leaves are scarcely above the ground; the petals, too, are tipped with yellow instead of green.—H. HARRIS CREWE.

***Berberis Aquifolium* for Winter Beds.**—In a dwarf condition this is a most useful plant for furnishing beds in winter; its dark shining foliage looks all the brighter after rain, and in combination with spring flowers when crowned with large heads of yellow blossoms, it is also effective, especially when associated with such plants as *Silene*, *Saponaria*, or *Nemophila*.—J. G.

Chopped Furze v. Mice.—From experience I can testify that chopped Furze forms a complete preventive to the ravages of mice among either CROCUSES or Peas. The first year during which we occupied a new house in a garden, I had all my CROCUSES quite eaten away by mice, but after that I always placed a layer of Furze over the roots before filling in with the soil, and they were never afterwards touched.—M. ARCHER, *Drogheda*.

Double Blue Hepatica.—I should like to learn how to grow this with success. I have tried it in different kinds of soils and positions, and if it goes on much longer at its present rapid rate of decrease, I shall soon lose it altogether. The colour is so beautiful that it is well worthy of cultivation, and I shall be thankful for any information respecting it. Other varieties do well with me; all are now one mass of bloom, and since I have used the perforated zinc, recommended in your paper last year, I have managed to gather a few perfect blooms from *H. angulosa*.—ED. FARRER, JCN., *Petygarts Hill, Seaforth*.

Early Pruning of Roses.—Those who prune Roses early will in all probability get a lesson this season that may be instructive; they have been ever-green this winter, and I observe that the late frost has nipped the tender growths at the ends of the shoots, but as these will have to be cut away, no real injury will be sustained, as the buds at the base are still dormant; where, however, forcing was done some time since and the reserved buds have started, a short supply of bloom must inevitably be the result.—J. GROOM, *Henham*.

LAWSON'S HOLLY.

Ilex Aquifolium Lawsoniana is one of the most striking of all the Hollies, if not the most so. It is very near the Hodgkins Holly, with fine large leaves blotched with gold in a very effective and striking manner. The leaves are of good substance, and the plant vigorous. It is probably the finest-blotched Holly in existence.

The plant was sent out by the Lawson Seed and Nursery Company.—V.

TREES ON WHICH MISTLETOE GROWS.

I HAVE cultivated the Mistletoe on a great variety of trees, but have always failed to establish it on the Oak. It has germinated with me on that tree, and fixed its first radicle, and then died; and so I have not persevered. I am not sure that my failure has not been owing to the extreme dryness of our soil and atmosphere; so I am tempted to write and tell any of your readers who may wish to cultivate the plant, how it may be readily done on many trees (certainly on Apple, Poplar, Lime, and Hawthorn), in the hope that they will also try it on the Oak in a wet clay soil, where the atmosphere also is more or less humid. A healthy, smooth, thick branch should be chosen tolerably near to the trunk, where the bark is young, healthy, and smooth, and free from cracks. The seed should then be squeezed out of the berry, and pressed firmly on to the bark with the finger till it is made to adhere, and there left. In a day or two it will be found to have dried hard upon its bed, if unmolested by birds. If sown now, it will soon put forth two radicles, which will fix themselves in the bark on each side. These will form two separate plants, one of which will probably soon die, or be pushed out, or starved by its more vigorous twin-brother or sister (for the plant is dioecious). It will remain till autumn or next spring without any other outward growth than these two little, green, arched radicles. The next step is for each radicle (if both live) to put forth its two first leaves; in this state it again remains for another year, and not till after the third year does it get to any considerable size. I cannot help thinking that the common Mistletoe may be induced to establish itself on the Oak under favourable circumstances, yet I am told that the Oak Mistletoe is quite another species, and peculiar to that tree. Of this I have never been able to judge, as I have never seen it on the Oak. If an attempt is to be made this year, it should be done immediately, for the seeds are dropping fast. H. W.

— Some time ago I saw it mentioned in the "Hereford Times" that Mistletoe may be seen growing on Oak trees at Saltmarsh Castle, near Bromyard. We have here in the pleasure grounds one bunch growing on a grand old Acacia tree, which girths 10 ft. at 3 ft. from the ground, the bunch of Mistletoe being quite 18 ft. in diameter. There are several smaller bunches growing on other Acacia trees here; Mistletoe is also abundant on the Apple, and

near here I have seen it on the Poplar. The Thorns, both in the pleasure grounds and park, are well furnished—indeed, in some cases, overrun—with it.—JOHN GOUGH, *Westwood Park, Droitwich*.

— Mr. Pink (p. 221) can only record one instance of the Mistletoe on the Acacia. I have seen it on the Acacia at Alderley in Gloucestershire, where it also grows on the Chestnut and Lime; also at several places under the Mendip Hills, especially at Congresbury and Banwell; but it is very unusual. As compared to its occurrence on the Apple, it is as 1 to 25.—HENRY N. ELLACOMBE, *Bitton*.

NEW PLANTS.

Hypolytrum latifolium.—A graceful, broad-leaved Cyperus, from Ceylon and the Malayan Archipelago. It forms a useful, ornate, grassy-habited plant, bearing panicles of brownish flowers. It was sent to Kew from Ceylon by Dr. Thwaites, and deserves notice as a warm conservatory plant.—"Botanical Magazine," t. 6282.

Stenandrium igneum.—A dwarf-growing, fine-foliaged Acanthad from Peru, having oblong leaves of a deep metallic green colour, the midrib and principal veins being bordered with yellow, as in *Sanchezia nobilis*, the under sides of the leaves being dull purple. It is decidedly distinct and ornamental, and well deserves culture as a stove fine-foliaged plant.—"L'Illustration Horticole," pl. 266.

Lilium concolor var. *luteum*.—The crimson, erect-flowered *Lilium concolor* is tolerably well known in our gardens, but not so this distinct yellow-flowered plant, which will be welcomed by all Lily growers as affording a charming contrast to those of the typical form of the species. The size and shape of the flowers, habit of growth, &c., are the same as those of the type.—"Gartenflora," t. 855.

Curmeria picturata.—A low-growing South American stove Aroid, which in general appearance resembles some *Marantas*, the broad, undulate, margined, oblong, green leaves having a feathered band of silvery grey on each side the mid-rib. It may be grown as a fine-foliaged plant, but is not more showy than are many *Marantas*.—"Gartenflora," t. 891.

Torenia exappendiculata.—A rather slender-growing herb, bearing opposite zig-zag branches with thickened points. The purple and white tubular flowers are borne in clusters towards the apices of the branches, and are less showy than those of any other *Torenia* we know.—"Gartenflora," t. 892.

Calathea (*Maranta*) *Leopardina*.—A graceful-habited plant, having oblong, light green leaves blotched on each side; the mid-rib with darker velvety green. No improvement on the older cultivated kinds.—"Gartenflora," t. 893.

Solanum acanthoides.—A sub-shrubby, Brazilian plant, the tomentose stems of which are clothed with pinnatifid leaves often 1 ft. or more in length, the large purple flowers being borne in panicles at the apex of the young growth. The individual flowers are fully 2 in. in diameter and very showy. The plant deserves culture as a fine-foliaged, conservatory plant, or as a flower garden ornament during the summer months.—"Botanical Magazine," t. 6283.

Gongora portentosa.—One of the largest and most ornate of all the species of this curious genus of Orchids. It is a native of New Granada, where it was discovered by Mr. Wallis in 1868, and it has since flowered in several collections. The large insectiform flowers are borne on a drooping spike 1 ft. or more in length, and are of a soft, rosy colour generally, but here and there suffused with yellow or orange, the lip being profusely dotted with red.—"Botanical Magazine," t. 6284.

Boronia elatior.—A free-growing, greenhouse shrub, a native of South-West Australia, whence it was introduced by Messrs. Veitch & Sons. Nearly fifty species are known, but none are prettier than the present plant when clothed with wreaths of pinkish-purple flowers and berry-like buds. The plant was figured in *THE GARDEN*, Vol. X., p. 312, where the more important species of *Boronia* are described. It well merits culture.—"Botanical Magazine," t. 6285.

Pectis angustifolia.—A dwarf, yellow-flowered, compositae annual herb, native of New Mexico and Western Texas, whence it has been introduced by Mr. W. Thompson, of Ipswich.—"Botanical Magazine," t. 6286.

Camassia esculenta var. *Leichtlini*.—A pallid or creamy-white variety of a well-known hardy plant. It is a native of British Columbia, where it was first discovered by Mr. John Jeffrey in 1853. It has been introduced and cultivated by Herr Max Leichtlin, of Baden-Baden. If the flowers were really pure white, this plant would be an acquisition.—"Botanical Magazine," t. 6287.

CULTURE OF BALSAMS.

BALSAMS are exceedingly useful during autumn, both for conservatory and sitting-room decoration. They may be easily grown into specimens 18 in. or 20 in. high and 3 ft. in circumference, or, with a little extra care and a suitable place in which to grow them, they may be had 3 ft. high and as many through. I have grown them many years ago 4 ft., and occasionally 4½ ft. in diameter. Balsams have naturally a tendency to run into many varieties, the seed of one plant scarcely ever producing two alike. The double Camellia-flowered varieties are those which are most esteemed, their blossoms sometimes rivalling in beauty those of a finely-striped or flaked Carnation. In order to secure successions of bloom, seeds should be sown at two or three different times between the middle of March and the end of April. As the Balsam is of a vigorous habit, it is not important what kind of soil is used, provided it is of a light nature and tolerably rich. When the seeds are sown, the pot containing them should be plunged in a mild hotbed, and in a few days the young seedlings will make their appearance. As soon as they are sufficiently large to handle, they must be potted into 3-in. pots in soil of the same temperature as that from which they have been taken. They should be potted as deeply as possible without burying the lower leaves. At this period of their growth, the best position for them, when it can be afforded, is a small hotbed, where they can receive the treatment necessary to insure a dwarf and healthy growth. Great care must be taken to keep the plants as near the glass as possible, or they will soon grow up lanky and weak. When they have taken hold of the new soil, they should have a little air given on all favourable occasions. This is essential, in order to ensure a stubby, robust growth. When the pots have become filled with roots (but not pot-bound), they must be shifted into pots a size larger, an operation which must be repeated till they are potted into the size in which they are intended to bloom. Many are satisfied to bloom their Balsams in 7-in. or 8-in. pots, and if they are healthy, useful plants may be grown in that size; but to have fine specimens, 3 ft. or 4 ft. in diameter, fit for exhibition, they must be grown in 12-in. or 13-in. pots. As soon as the lower shoots can be got hold of, they must be tied or pegged down, and every fresh tier of shoots must be dealt with in the same manner. If they can be kept in pits near the glass, with plenty of air, and all the flower-buds picked off as they appear, till they are required to bloom, they will grow like Willows; and when the roots have thoroughly permeated the soil they will stand any amount of manure-water. When I have wished to have large specimens, I have given manure-water at every other watering, increasing it in strength as the plants increased in growth. Balsams treated in this way, and grown to the height of 3 ft. or 3½ ft., and from 3 ft. to 4 ft. in diameter, with side branches from top to bottom, all covered with beautiful, Carnation-like flowers.

R.

NEW HOLLYHOCKS.

In the north of England, and especially in Scotland, cultivators are remarkably assiduous in the matter of Hollyhock showing, and there is every inducement held out to raisers of this handsome flower to persevere in obtaining new varieties; whereas in London one rarely sees a Hollyhock of northern production, as there are no exhibitions at which prizes are offered for them; in fact, I believe that the only opportunity one has of seeing any of the new varieties of Hollyhock is when Mr. Chater sends a few flowers to one of the meetings of the Royal Horticultural Society during July or August. Those who wish to possess a row or two of Hollyhocks should at once obtain plants from a nursery, as they are at the present season of the year in a somewhat dormant condition, and travel better than when more advanced in growth. Strong, vigorous plants can be had in large 60-sized or small 48-sized pots; they should be housed in a cold frame and be shifted once into 32-sized pots before being planted out in May to flower during the summer. In 1876, Messrs. Downie & Laird distributed the following flowers:—Countess of Kellie, bright rosy-salmon, large, full flowers of perfect shape, forming a grand spike; Duke of Edinburgh, dark ruby-crimson, very large and full, a grand show flower; Lady Maxwell, rosy-blush suffused with carmine, a beautiful soft flower of fine form and substance; Lord Abinger, bright rosy-crimson, large and full; Mrs. Cowan, clear rosy-peach, very fine and full; and Maréchal Macmahon, bright scarlet,

large, and of extra fine form and quality. The new varieties to be distributed this spring consist of Amœna, delicate, soft, rosy-salmon, extra fine; Apollo, fine dark rosy-peach; Caloris, delicate rosy-peach, forming a fine spike; Neptune, bright ruby-crimson—whether grown for its spike or for single blooms, this makes a grand show variety; Pluto (dark rosy-purple, very fine), and Stella (glowing reddish-scarlet), form fine spikes. I should recommend, as a selection of eighteen of the finest of the northern flowers, the following, viz.:—Andrew Goodfellow, dark rosy-crimson, very fine; Andrew Jamieson, deep-shaded rose; Archbishop, light rosy-crimson, shaded with salmon, very fine; Black Douglas, intense black; Brilliant, bright rosy-scarlet; Countess of Craven, delicate rosy-peach; Cygnet, pure white; Edward Caird, bright ruby-scarlet; F. G. Doogall, glowing rosy-purple; Gem of Yellows Improved, deep yellow; James Neilson, bright rosy-salmon; James Whitton, salmon flushed with rose; John Gair, dark rosy-peach; Lady Home Campbell, pure white; Lady Eglinton, bright cherry-red; Miss Meiklam, light rose, very fine; Mrs. Graham, light rosy-lilac; and Primrose Gem, deep primrose.

D.

PLATE LXVI.

THE PITMASTON PEAR.

Drawn by H. HYDE.

THIS fine Pear, which originated at Pitmaston, in Worcestershire, is stated to be the result of a cross between Glou Morceau and Duchesse d'Angoulême. It is one of the largest melting Pears in cultivation, and is an excellent bearer both on walls and in open quarters. It was originally brought into notice by Mr. Turner, of Slough, about the year 1836, and was at first named Pitmaston Duchesse d'Angoulême, but it has since been found to be so wholly distinct from the Duchesse d'Angoulême and also from all other Pears, as to well deserve the name which we have given it.

Concerning this fine and large Pear, Mr. Wildsmith writes to us as follows:—Of recently-introduced Pears not one with which I am acquainted is in all points so good as this; as regards size, appearance, quality of flesh, and free bearing, it is of the first order. We have it growing on a west wall, and also as a pyramidal trained tree in an open situation, in both of which positions it does remarkably well, and except that the fruit on the wall tree is better coloured, and ripens ten days or a fortnight earlier than that on the pyramidal trained tree, it is equally good in either position. It comes into use about the beginning of October, and if gathered from the tree at different times, it may be had in use until the end of November; it therefore forms a succession to the Marie Louise, which in some respects it resembles, though it is much larger.

Mr. Wilmot, of Isleworth, who kindly furnished the fine specimen from which the annexed illustration was prepared, speaks very highly of this Pear, and is planting it largely. Most of his trees of it were grafted on old useless sorts that were cut back, but he has also some on the Quince stock, under which condition established trees yield larger fruit but do not bear so abundantly as those on the trees that were cut back. For walls, espaliers, or dwarf pyramids, this Pear is well adapted, but for standards it is not so suitable, as the fruit, which often attains a weight of 2 lb., is much too heavy for that form of tree. In whatever way it is grown, however, it has a tendency to produce fruit-buds at the extremities of the shoots; it is therefore necessary to cut back the latter to a leaf-bud after the bloom shows in order to obtain leading growths. As regards flavour Mr. Webber, of Covent Garden, asserts that, with the exception of Marie Louise, it is the best-flavoured Pear that comes into market.

Botryanthus conicus.—Eleven years ago I found in the Campagna and other parts of Italy a Muscari exactly intermediate between *M. botryoides* and *M. racemosum*, which has always puzzled me. I brought home bulbs, and they have flourished and increased in my garden. A short time since I submitted a flowering bulb to the inspection of Mr. Baker at Kew, and he pronounced it to be *Botryanthus (Muscari) conicus* of Jordan. In leaf, colour of bloom, and general habit of growth, it comes, as I said before, just midway between *M. botryoides* and *M. racemosum*. It is rather a shy bloomer, and has a habit of splitting itself up into numerous minute bulbs, which form a tangled mass.—H. HARPUR CREWE.

THE FLOWERS OF PEAR

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vineries.—As soon as the shoots are sufficiently advanced to show which are the best placed, and which are likely to produce fruit, remove such others as are not required. As they advance in growth tie them to the wires in the places which they ought to occupy, bringing them into their exact positions by degrees, for if bent too much at once they are liable to break. Close the house early every afternoon, and syringe overhead freely with tepid water. See that inside Vine borders are sufficiently moist all the way down; through inattention to this, Vines suffer more frequently and seriously than from any other cause. The appearance of the surface of the soil through daily syringing is very deceptive, as the top will often seem wet enough when below it is much too dry. Naturally there is a disinclination to disturb the soil in which the roots ought to be thickly interspersed by using a fork or other implement to examine what is the actual condition of the bottom portion of the border, but it is very easy to ascertain the exact state as to moisture from the surface down to the drainage by the use of the little implement which I have before mentioned. It consists of a hollow tube of thin iron open at both ends, in diameter something like an ordinary gun barrel; this, thrust down as far as the drainage, of course comes out charged with the soil, when, by pushing it out with a stick something like that used in the case of a boy's popgun, the condition of the soil may be seen at a glance. By using the implement in different parts of the border, the state of the whole can be ascertained with the slightest possible injury to the roots; it will involve little cost and equally little labour, and is much better than remaining in doubt as to the condition of the soil.

Peaches under glass started some time ago will by this time be in full bloom; go over them daily, and strike the trellis to which they are trained with the hand; the vibration thus produced, if done in the middle of the day when the pollen is dry, will help to disperse it and assist the setting of the fruit. Again examine the soil to see that it is sufficiently moist right through the border as far as the roots penetrate; the Peach is a water-loving plant, and will not succeed if the soil be at all dry. Give air more or less every day, according to the state of the weather, but avoid cold draughts coming in contact with the young and tender foliage. Be careful not to allow anything like overheating, as Peaches cannot bear, especially in their early stages, being hurried; a temperature of 46° or 48° is quite enough at night, and it should not be allowed, even on sunny mornings, to rise more than 10° above that, without giving air.

Tomatoes.—Some seeds of these should now be sown in heat, as it is necessary to get the plants sufficiently early to become established before planting-out time, especially in the northern parts of the kingdom; otherwise if we happen to have a senseless, indifferent summer, the cold autumn weather sets in on them before they have a chance of bearing much. Previous to putting them out they should be moved into pots large enough to keep the plants growing, though the bearing capabilities of the Tomato are rather improved than otherwise through being somewhat confined at the roots. The seeds may be sown in an ordinary 8-in. or 10-in. flower-pot, or a seed-pan, covering them with $\frac{1}{2}$ in. of soil, or half-a-dozen seeds each may be put into 2-in. or 3-in. pots, afterwards thinned out to a couple of plants, and potted on as they need it. As soon as the seed vegetates keep the plants near the glass, or they will get drawn up so weakly as to lack their requisite vigour.

Kitchen Garden.—Some seeds of Brussels Sprouts should now be sown. It is well to make sowings of this excellent vegetable twice—at the present time and again later on—the later sowing will form sprouts late in the autumn that will stand better through the winter than those sown earlier, but the latter furnish the finest produce. The Brussels Sprout is a vegetable to which a long season of growth is indispensable for its full development, and if not sown early, no subsequent treatment will enable the plants to bear the full weight of crop of which they are capable. With many the plants are never half grown through too late sowing and growing in alternate rows with Potatoes and other vegetables, whereby there is nothing gained but a decided loss, as the Sprouts reduce the produce of the crop grown with them, and are alike injured. **Cauliflowers.**—A little Cauliflower seed should also be sown at the same time. In all cases, it is advisable to coat the seeds of all the Brassica tribe with red lead, as a preventive to the attacks of birds, for although some cultivators assert that it does not always act as a preventive, yet where the coating is efficiently done, no birds will take the seeds. A little sweet oil used in place of water before the powdered lead is dusted upon the seed will cause it to adhere better, and prevent it being removed either by wet or by coming in contact with the soil.

The seed should always be well shaken or stirred with the hand after the lead is dusted on, so as to cause it to stick closely; then spread out thinly for a day or two to dry before sowing. It is the omission of the performance of these details that is so frequently the cause of failure.

Potatoes.—More Early and Second Early Potatoes should now be planted. Nothing of late years has been more perplexing to amateurs than the selection of the best varieties of this esculent for cultivation; the immense number of new kinds that have been offered to the public with the highest possible commendations have in very many cases proved undeserving of the character with which they were heralded. With few exceptions the high-priced American kinds have turned out heavy croppers, but utterly worthless in quality, being far inferior to many of the old well-proved British sorts. For the earliest in most soils Kidneys are preferable to the Round varieties, being much better for the table in a young state. As representatives of the old well-known Ashleaf Kidney, there is nothing to surpass Lee's Hammersmith Kidney, Mona's Pride, and Myatt's Ashleaf; they are all excellent in quality, very early, and much heavier croppers than the Ashleaf, succeeding better in old gardens and soils not the best adapted for Potato culture. As an Early Round kind, Early Oxford is a good sort and a free cropper; as a Second Early, nothing yet surpasses York Regent, either for its eatable properties, weight of produce, or adaptability to any soil where Potatoes can be grown; and if the seed have been properly prepared as suggested some time ago, by being subjected to sufficient light to solidify the sprouts, and some are planted at the same time as the Early Kidneys, they will be ready for use a month later, and will be found much better in quality than any of the Early Round kinds—also as a late sort to come in for use through April and May, and up to the time that the earliest are ready I should recommend amateurs to grow Paterson's Victoria; it will at this time succeed the Regents, and from its later disposition to sprout, will be found the best at this season. Any two of the above Kidneys, with the Regents and Victorias, are ample for a supply all the year round.

Peas sown in tines or boxes should now be planted out; give them a sheltered situation in the driest part of the garden, and choose a day when the soil is tolerably dry; where it is so moist as to become compressed by treading upon, boards should be used as before recommended while putting in these and other early vegetables. The little extra labour thereby involved will be well repaid by the better condition in which the ground will be left, as when trodden solid through this and the following month, and dry weather ensues, it becomes so hard and impervious to the roots, that even the strongest-growing plants fail to succeed in it as they otherwise would. As soon as the Peas are planted draw a little soil to them, and at once stake them with small sticks, placing outside these a few branches of evergreens to protect them from cold winds. Keep a daily look-out that sparrows do not molest them; I have seen these birds attack early Peas even up to the time that the flowers were formed, nipping out the extreme points, after which the plants make but slight progress, for although they make an attempt to break out lower down, yet the produce of the early sowings that have so suffered is never more than half a crop. Except in very light soils, ground that was dug and ridged up in the autumn from the excessive wet and absence of frost to pulverize it, will this season require more stirring before cropping than the ridges being levelled in the usual way, as where the soil is heavy, it has become as close and solid as it would be in ordinary seasons if not dug at all, and it will be necessary to re-dig it, after which, so far as possible, let it remain for a short time before cropping. In all cases the fork will be a better implement than the spade for this work; leave the surface as light and open as possible.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

March 26.—Potting off spring-struck Lobelias and Petanias. Shifting young Melon plants into 6-in. pots. Cutting up a large Dendrobium noble, and making three plants of it. Sowing all annuals, also Scotch Kale, Brussels Sprouts, Savoy, Cottager's Kale, a little Veitch's Autumn Giant Cauliflower, and Egyptian Green-flesh Melon; likewise sowing Grass seeds in bare places on lawn; also more Radishes, Lettuce, Waicheren Cauliflower, and Celery in heat. Putting in Purple King Verbena cuttings and Pink pipings. Plunging Rhododendrons, Azaleas, and spare Lilacs. Putting in another forcing of Seakale, and covering up a number of crowns out-of-doors with flower-pots, over which soil is put to keep them as late as possible.

Moving *Salvias* to cold pits; also *Balm*. Tying up Lettuces to blanch. Putting supports to Strawberries that have set their fruit. Keeping *Cattleya* and *Dendrobium*-houses at 65° during the night. Looking over *Saccolabiums* for scale. Watering Peach trees in second and third houses; also Radishes in frames. Levelling Celery land for Peas. Digging in litter round Globe Artichokes. Turning manure for Potatoes. Top-dressing Japan Lillies with peat and sheep manure. Earthing up Cucumbers and Cabbage plants. Clipping Holly hedges. Raking flower borders. Hoeing among Wallflowers, Sweet Williams, and Lettuces.

March 27.—Potting Azaleas, Camellias, *Cytisus*, Palms, and *Ericas*; also potting spring-struck *Pelargoniums*, *Alyssum*, *Coleus*, seedling *Petunias*, and *Balsams*, placing the latter in Cucumber-pit. Potting *Houletia chrysantha* in Moss, crocks, and charcoal, and *Sobralia virginialis* in Moss. Sowing *Solanum capsicastrum* and French Beans in heat, and another frame of Radishes. Planting China Roses; a few Canlilowers between cases out-of-doors. Beginning to plant Strawberries, taking them up with a ball and planting them with a trowel; also putting out Cucumbers and transplanting *Balm*. Plunging young Vines in span-roofed pits. Putting Hollyhocks out-of-doors, and potting off bedding plants that are established into cold pits. Preparing border for Carnations. Top-dressing pot Vines with loam and manure, giving them a little Standen's Manure once a week, and watering them every other day. Thinning Muscat Grapes and Strawberries. Pruning Roses. Making alleys deeper between Asparagus beds with a view to afford them better drainage. Keeping East India house at 68° during the night.

March 28.—Potting Ghent Azaleas, *Dielytras*, and *Spiræas*. Shaking-out and re-potting *Cattleya speciosissima*, and potting some *Calathes* in loam, peat, sand, charcoal, and manure. Putting fresh loamy peat to the roots of *Phajus Wallichi*; supplying *Dendrobium lasioglossum* with fresh Moss, and placing pieces of wood amongst it for the young growths to root upon. Sowing Peas, Long-pod Beans, Asparagus, and Spinach. Planting Fancies, Neapolitan Violets, and Sweet Peas. Putting in cuttings of *Iresine Lindeni* and *Alternanthera*. Sprinkling horse-droppings in Gardenia-house. Digging land for permanent Seakale, and manuring ground for remainder of autumn-sown Canlilower, placing Celery plants in cold pits. Earthing hand-light Canlilowers; also autumn-sown Cabbage. Keeping first Peach-house at 60° at night and 65° by day with fire-heat, leaving night air on all the Strawberry houses and pits.

March 29.—Potting *Petunias* and *Fuchsias*; also a batch of French Beans for front of late Vineries. Shifting *Cyrtopodium punctatum* into good rough peat. Sowing Cabbage and Canlilower to be ready September 1; also more Parsley, Alexandra and Neapolitan Lettuce, Early Dutch Turnips (to be ready June 10), Early Horn Carrots (to be ready June 19), and main summer crop of Cucumbers. Planting Apricot and Pear trees on walls. Transplanting Cabbage plants in drills; also last of autumn-sown Cauliflower. Pricking out Everlastings. Preparing bed in the open ground for Radishes. Digging vacant borders. Earthing up Cucumbers. Salting Asparagus and Seakale land. Potting Ferns. Putting labels to Orchids. Hanging *Phalaenopsis* near glass. Sowing Asters, Stocks, Sweet Peas, Lupines, Sunflowers, Carnations, and Larkspurs; also full crop of Radishes and a little Pine-apple Beet. Planting out Lily of the Valley and Hollyhocks. Pricking out *Celosias* and second-sown Cauliflowers. Putting in *Scatellaria* and scented *Verbena* cuttings, and moving *Mignonette* into cold frames. Tying down Vine shoots. Trenching vacant quarters. Putting soil into pit for Vines. Turning manure for Celery. Earthing up Melons, making the surface firm. Stopping shoots of Cucumber plants that are growing freely.

March 31.—Sowing main crop of Beetroot, Salsafy, *Scorzouera*, all hardy herbs, including Borage, Angelica, and Fennel. Planting Strawberry plants, and more Canlilowers and Lettuces; likewise *Pinus anstriaca* and Yews, and Berberies; also Lily of the Valley, a pit with Vines and a bed of Carnations. Putting *Amaryllis* on Fig-house shelves; *Ageratum*, *Salvias*, *Petunias*, and *Verbenas* into cold pits, and getting Lilacs out of doors. Putting strings to rows of Strawberries on shelves to support the fruit. Staking Hollyhocks and *Mignonette*. Earthing up Broad Beans, also autumn-sown Cabbages. Mowing Grass verges, hoeing among growing crops, clearing Violet beds. Plants in flower.—*Rhododendrons*, Azaleas, *Cinerarias*, *Primulas*, *Ageratum*, *Epacris*, *Heaths*, Lilacs, *Forget-me-nots*, *Cytisus*, Wallflowers, *Tulips*, *Hyacinths*, *Amaryllis*, *Gardenias*, *Crocuses*, *Mignonette*, *Kalmia glauca*, and *K. latifolia*, *Camellias*, *Pelargoniums*, *Lily of the Valley*, *Viburnum plicatum*, *Acacias* of different sorts, *Roses*, *Dielytras*, *Dentzias*, *Correas*, *Tydeas*, *Daphne indica rubra*.

Hardy Flowers.

Auricula-growers should now give their plants all the air possible, as they are making rapid growth, and should on no account be allowed to become drawn. They promise to flower somewhat early, and exposure will tend to retard them. When a mild, soft shower occurs, the lights may be removed to give the plants the benefit of it. Top-dressing should be finished at once, as surface roots will be getting active. Wallflowers should be sown at once in order to have the plants strong for transplanting in May. I have sown Harbinger, Young's Blood Red, Golden Tom Thumb, and Belvoir Castle Dwarf Yellow, and, indeed, they are already coming through the soil. Generally Wallflowers are sown much too late, and dry weather comes in before they can be transplanted. Those who grow for the London markets always make a point of sowing early in the year, Marigold, *Mimulus*, Pansy, *Petunia*, Primrose, *Polyanthus*, Stock, Viola, and *Zinnia* seeds, should all be sown now—those that require it in heat, the others in the open ground or in boxes or pans in cold frames. The season is rapidly advancing, and there is nothing like strong plants when required to plant out. Beds and lines of *Crocuses* require to have the decaying flowers picked off to make room for successional blooms. The varieties do not always come into flower at the same time, and the purple varieties are generally the latest. *Ranunculuses* should be planted without delay. The wet winter has justified spring in preference to autumn planting, but it is now high time it was done. The soil should be rich and light, and the roots placed at least 2 in. below the surface; in the event of severe frost setting in, a few old mats spread over the surface of the beds at night will save them from injury. Worms are apt to be troublesome, working among the bulbs and throwing them out of the ground, but they can be kept in check by pouring lime-water about their runs. *Anemones* are coming through the soil, and should be helped by stirring the surface about them. What a splendid object *A. fulgens* is just now with its showy scarlet blossoms, some of them of very large size and with petals measuring nearly an inch across! I have by the side of it *A. apennina*, which is also throwing up its charming pale mauve blossoms.—D.

PROFITABLE GARDENING FOR COTTAGERS.

The Cottager who wants to grow fruit fit for preserving for sale, will do well to turn his attention to the cultivation of Raspberries and Strawberries, both of which yield heavy crops, and are sure to command a ready sale at good prices. Of the Strawberry some account was given last week (see p. 211), and as regards the Raspberry, as it naturally likes a shady situation, good crops of it may be obtained from canes grown under fruit trees, where little else would succeed. Let plantations therefore of one or two good kinds be made under fruit trees, and never dig amongst them, as it injures the roots which ramify close to the surface of the soil. Keep weeds down with the hoe. In July when the fruit is ripening, if the weather be dry give abundance of water, otherwise the fruit will be small; even liquid manure given every week at that time has a wonderful effect in increasing the crop. In winter give a coating of manure the liquid portion of which gets washed into the soil during winter, and about February prick in the soiled part with a spade or fork by merely turning it over and covering it with one or two inches of the soil. Cut down the canes to 3 ft., and stake them in the usual way. Quite as much fruit will be got from a cane 2½ ft. in length as from one 4 ft., and in the case of a low fruiting cane, the fruit has a better chance of escaping without injury from birds. The suckers which grow rapidly in summer, spread out their foliage, and cover the fruit with 3 ft. canes, and the finest fruit is always found under dense foliage. In order to give an ideal of the value of a Raspberry plantation under fruit trees, I may state that one 20 yards long and 4 yards broad in a north aspect has been known to yield from 50 to 60 quarts of fruit during the summer, which at 6d. per quart, produce from 25s. to 30s. The fruit should be gathered three or perhaps four times a week. The Raspberry crop never fails like that of other fruit, but the plants must be freely watered, as water is always beneficial, especially during a dry season, when the fruit is ripening. H. T.

Preserved Peas.—The question of the legitimacy of the coloration of Peas by copper has been discussed at the Académie des Sciences of Paris on one or two recent occasions, and the result arrived at was similar to that respecting the adulteration of wine by fuchsine. It was strongly urged by M. Pasteur and others that if not a technical adulteration which could be shown to be injurious, it was at any rate a dishonest admixture, and that the preserved Peas which are coloured by copper ought to be distinctly designated as such; so that the consumer might at any rate choose for himself whether he would or would not consume habitually the small portions of copper contained in them.—*Lancet*.

THE PLANT-LORE OF SHAKESPEARE.

ALL the commentators on Shakespeare are agreed upon one point, that he was the most wonderful many-sided writer that the world has yet seen. Every art and science are more or less noticed by him, so far as they were known in his day; every business and profession are more or less accurately described; and so it has come to pass that, though the circumstances of his life are pretty well known, yet the students of every art and science, the members of every business and profession, have delighted to claim him as their fellow-labourer. Books have been written at various times by various writers, which have proved (to the complete satisfaction of the writers) that he was a soldier, a sailor, a lawyer, an astronomer, a physician, a preacher, an actor, a courtier, and I know not what else besides.

I also propose to claim him as a fellow-labourer. A lover of flowers and gardening myself, I claim Shakespeare as equally a lover of flowers and gardening; and this I propose to prove by showing how, in all his writings, he exhibits his strong love for flowers, and a very fair, though not perhaps a very deep knowledge of plants; but I do not intend to go further. That he was a lover of plants I shall have no difficulty in showing; but I do not, therefore, believe that he was ever a professed gardener, and I am quite sure he can in no sense be claimed as a brother-botanist, in the scientific sense of the term. His knowledge of plants was simply the knowledge that every man may have who goes through the world with his eyes open to the many beauties of Nature that surround him, and who does not content himself with simply looking, and then passing on, but tries to find out something of the inner meaning of the beauties he sees, and to carry away with him any of the lessons which they were doubtless meant to teach. But Shakespeare was able to go further than this. He had the great gift of being able to describe what he saw in a way that few others have ever arrived at; he could communicate to others the pleasure that he felt himself, not by long descriptions, but by a few simple words, a few natural touches, and a few well-chosen epithets, which bring the plants and flowers before us in the freshest, and often in a most touching way.

For this reason the study of the plant-lore of Shakespeare is a very pleasant study, but there are other things which add to this pleasure. One especial pleasure arises from the thoroughly English character of his descriptions. It has often been observed that wherever the scenes of his plays are laid, and whatever foreign characters he introduces, yet they really are all Englishmen of the time of Elizabeth, and the scenes are all drawn from the England of his day. This is certainly true of the plants and flowers we meet with in the plays; they are thoroughly English plants that (with very few exceptions) he saw in the hedgerows and woods of Warwickshire, or in his own or his friends' gardens. The descriptions are thus thoroughly fresh and real; they tell of the country and of the outdoor life he loved, and they never smell of the study lamp. In this respect he differs largely from Milton, whose descriptions (with very few exceptions) recall the classic and Italian writers. He differs, too, from his contemporary Spenser, who has certainly some very sweet descriptions of flowers, which show that he knew and loved them, but has chiefly allusions to classical flowers, which he uses in such a way as to show that he often did not fully know what they were, but used them because it was the right thing for a classical poet so to do. Shakespeare never names a flower or plant unnecessarily; they all come before us, when they do come, in the most natural way, as if the particular flower named was the only one that could be named on that occasion. We have nothing in his writings, for instance, like the long list of trees described (and in the most interesting way) in the first Canto of the First Book of the "Faerie Queene," and indeed he is curiously distinct from all his contemporaries. Chaucer, before him, spoke much of flowers and plants, and drew them as from the life. In the century after him Herrick may be named as another who sung of flowers as he saw them, but the real contemporaries of Shakespeare are, for the most part, very silent on the subject. One instance will suffice. Sir Thomas Wyatt's poems are all professedly about the country—they abound in woods and vales, shepherds and swains—yet in all his poems there is scarcely a single allusion to a flower in a really natural way.

And because Shakespeare only introduces flowers in their right place, and in the most purely natural way, there is one necessary result. I shall show that the number of flowers he introduces is large, but the number he omits, and which he must have known, is also very large, and well worth noting. He has no notice, under any name, of such common flowers as the Snowdrop, the Anemone, the Forget-me-Not, the Fox-glove, the Lily of the Valley, and many others which he must have known, but which he has not named; because when he names a plant or flower, he does so not to show his own knowledge, but because the particular flower or plant is wanted in the particular place in which he uses it.

Another point of interest in the plant-lore of Shakespeare is the wide range of his observation. He gathers flowers for us from all sorts of places—from the "turf mountains" and the "flat meads;" from the "bosky acres" and the "unshrubbed down;" from "Rose-banks and hedges unpleached." But he is equally at home in the gardens of the country gentlemen with their "pleached bowers and leafy orchards." Nor is he a stranger to gardens of a much higher pretension, for he will pick us famous Strawberries from the garden of my lord of Ely in Holborn; he will pick us White and Red Roses from the garden of the Temple; and he will pick us "Apricocks" from the royal garden of Richard the Second's sad queen. I propose to follow Shakespeare into these many pleasant spots, and to pick each flower and note each plant which he has thought worthy of notice. I do not propose to make a selection of his plants, for that would not give a proper idea of the extent of his knowledge, but to note every tree, and plant, and flower that he has noted; and as I pick each flower, I shall let Shakespeare first tell us all he has to say about it; in other words, I shall quote every passage in which he names the plant or flower; for here, again, it would not do to make a selection from the passages, my object not being to give "floral extracts," but to let him say all he can in his own choice words. There is not much difficulty in this, but there is difficulty in determining how much or how little I can quote. On the one hand, it often seems cruel to cut short a noble passage in the midst of which some favourite flower is placed; but, on the other hand, to quote at too great a length would extend these papers beyond the limits that the editor of THE GARDEN could spare. The rule, therefore, must be to confine the quotations within as small a space as possible, only taking care that the space is not so small as entirely to spoil the beauty of the description. Then, having listened to all that Shakespeare has to say on each flower, I shall follow with illustrations (few and short) from contemporary writers; then with any observations that may present themselves in the identification of Shakespeare's plant with their modern representatives, finishing each with anything in the history or modern uses and cultivation of the plant that I think will interest readers. For the identification of the plants, we have an excellent and trustworthy guide in John Gerard; he was almost an exact cotemporary of Shakespeare. Gerard's life ranged from 1545 to 1612, and Shakespeare's from 1564 to 1616. Whether they were acquainted or not we do not know, but it is certainly not improbable that they were; I should think it almost certain that they must have known each other's published works.

Of other works illustrating the plant-lore of Shakespeare, I need only mention "Shakespeare's Garden," by Sidney Beisly, 1864. I have to thank him for information on one or two points, but on the whole it is not a satisfactory account of the plants of Shakespeare, and I have not found it of much use.

My subject naturally divides itself into two parts—First, the actual plants and flowers named by Shakespeare; second, his knowledge of gardens and gardening. I now go at once to the first division, naming each plant in its alphabetical order:—

Aconitum.

K. Henry. The united vessel of their blood
Mingled with reason of suggestion
(As force perforce, the age will pour it in),
Shall never leak, though it do work as strong
As Aconitum or rash gunpowder.

2nd Henry IV., act. iv., sc. 4.

The plant here named as being as powerful in its action as gunpowder, is the *Aconitum Napellus* (the Wolf's-bane or Monk's-hood). It is a member of a large family, all of which are more or less poisonous, and the common Monk's-hood as much so as any. Two species are found in America, but, for the most part, the family is confined to the northern portion of the Eastern Hemisphere, ranging from the Himalaya through Europe to Great Britain. It is now found wild in a few parts of England, but it is certainly not indigenous; it was, however, very early introduced into England, being found in all the English vocabularies of plants from the tenth century downwards.

Its names are all interesting. Its Anglo-Saxon name was *thung*, which primarily meant anything very poisonous; it was then called *Aconite*, as the English form of its Greek and Latin name, but this name is now seldom used, being, by a curious perversion, solely given to the pretty little early-flowering Winter *Aconite* (*Eranthis hyemalis*), which is not a true *Aconite*, though closely allied; it then got the name of Wolf's-bane, as the direct translation of the Greek *lycoctonum*, a name which it had from the idea that arrows tipped with the juice, or baits anointed with it, would kill wolves and other vermin; and, lastly, it got the expressive names of Monk's-hood and the Helmet-flower, from the curious shape of the upper sepal overtopping the rest of the flower.

As to its poisonous qualities, all authors agree that every species is very poisonous, the *A. ferox* of the Himalaya being probably the most so. Every part of the plant, from the root to the pollen dust, seems to be equally powerful, and it has the special bad quality of being, to inexperienced eyes, so like harmless plants, that the poison has been often taken by mistake with deadly results. This charge against the plant is of long standing, dating certainly from the time of Virgil—*misericors fallunt aconita lygentes*—and, no doubt, from much before his time.

Yet, in spite of its poisonous qualities, the plant has always held, and deservedly, a place among the ornamental plants of our gardens; its stately habit and its handsome leaves and flowers make it a favourite. Nearly all the species are worth growing, the best, perhaps, being *A. Napellus*, with its white variety, *A. paniculatum*, *A. japonicum*, and *A. autumnale*. All the species grow well in shade and under trees. In Shakespeare's time Gerarde grew in his London garden four species—*A. lycoctonum*, *A. variegatum*, *A. Napellus*, and *A. pyrenaicum*.

Almond.

Thecites. The parrot will not do more for an Almond.

Troilus and Cressida, act v., sc. 2.

"An Almond for a parrot" seems to have been a proverb for the greatest temptation that could be put before a man. The Almond tree is a native of Asia and North Africa, but it was very early introduced into England, probably by the Romans. It occurs in the Anglo-Saxon lists of plants, and in the "Durham Glossary" (11th century) it has the name of the "Easterne nutte-beam." The tree was always a favourite both for the beauty of its flowers, which come very early in the year, and for its Biblical associations, so that in Shakespeare's time the trees were "in our London gardens and orchards in great plenty" (Gerarde). The name Almond comes to us through the French *amande* (Provençal, *amondala*), from the Greek and Latin, *amygdalus*. What this word meant is not very clear, but the native Hebrew name of the plant (*shaked*) is most expressive. The word signifies "awakening," and so is a most fitting name for a tree whose beautiful flowers, appearing in Palestine in January, show the wakening up of Creation. The fruit also has always been a special favourite, and though it is strongly imbued with prussic acid, it is considered a wholesome fruit. By the old writers many wonderful virtues were attributed to the fruit, but I am afraid it was chiefly valued for its supposed virtue, that "five or six being taken fasting do keepe a man from being drunke" (Gerarde). This popular error is not yet extinct.

As an ornamental tree the Almond should be in every shrubbery, and, as in Gerarde's time, it may still be planted in town gardens with advantage. There are several varieties of the common Almond, differing slightly in the colour and size of the

flowers; and there is one little shrub (*Amygdalus nana*) of the family that is very pretty in the front row of a shrubbery. All the species are deciduous.

Apple.

- (1) *Sebastian*. I think he will carry the island home and give it his son for an Apple.
Tempest, act ii., sc. 1.
- (2) *Malvolio*. Not yet old enough for a man, nor young enough for a boy, as a Codling when 'tis almost an Apple.
Twelfth Night, act i., sc. 5.
- (3) *Antonio*. An Apple cleft in two is not more twin Than these two creatures.
Twelfth Night, act v., sc. 1.
- (4) *Song of Winter*.
When roasted Crabs hiss in the bowl,
Then nightly sings the staring owl,
Love's Labour Lost, act v., sc. 2.
- (5) *Puck*. And sometimes lurk I in a gossip's bowl In very likeness of a roasted Crab; And when she drinks, against her lips I bob And on her withered dewlap pour the ale.
Midsommer Night's Dream, act ii., sc. 1.
- (6) *Antonio*. An evil soul producing holy witness Is like a villain with a smiling cheek,
A goodly Apple rotten at the heart.
Merchant of Venice, act i., sc. 3.
- (7) *Tranio*. He in countenance somewhat doth resemble you,
Biondello. As much as an Apple doth an oyster.
Taming of Shrew, act iv., sc. 1.
- (8) *Petruchio*.
What's this? a sleeve? 'tis like a demi-cannon.
What! up and down, carved like an Apple-tart?
Taming of Shrew, act iv., sc. 3.
- (9) *Fool*. Thy other daughter will use thee kindly; for though she is as like thee as a Crab to an Apple, yet I can tell what I can tell.
Lear. Why, what canst thou tell, my boy?
Fool. She will taste as like thee as a Crab to a Crab.
Lear, act i., sc. 5.
- (10) *Falstaff*. My skin hangs about me like an old lady's loose gown; I am withered like an old Apple-john.
1st Henry IV., act iii., sc. 3.
- (11) *1st Drawer*. What the devil hast thou brought there? Apple-johns? Thou knowest Sir John cannot endure an Apple-john.
2nd Drawer. Mass! thou sayest true; the prince once set a dish of Apple-johns before him, and told him there were five more Sir Johns; and putting off his hat, said, I will now take my leave of these six dry, round, old, withered knights.
2nd Henry IV., act ii., sc. 4.
- (11*) *Orleans*. English mastiffs . . . run winking into the mouth of a Russian bear, and have their heads crunched like rotten Apples.
Henry V., act iii., sc. 7.
- (12) *Shallow*. Nay, you shall see mine orchard, where in an arbour we will eat a last year's Pippin of my own grafting, with a dish of Carraways, and so forth.
Dary. There's a dish of Leather-coats for you.
2nd Henry IV., act v., sc. 3.
- (13) *Evans*. I pray you begone; I will make an end of my dinner. There's Pippins and cheese to come.
Merry Wives of Windsor, act i., sc. 2.
- (14) *Caliban*. I prythee let me bring thee where Crabs grow.
Tempest, act ii. sc. 2.
- (15) *Holofernes*. The deer was as you know in *sanguis*—blood; ripe as a Pomewater, who now hangeth like a jewel in ear of *cælo*—the sky, the welkin, the heaven; and anon falleth like a Crab on the face of *terra*—the soil, the land, the earth.
Love's Labour Lost, act iv., sc. 2.
- (16) *Petruchio*. Nay, come, Kate, come, you must not look so sour.
Katherine. It is my fashion when I see a Crab.
Petruchio. Why, here's no Crab, and, therefore, look not sour.
Taming of Shrew, act ii., sc. 1.
- (17) *Menenius*. We have some old Crab trees here at home that will not Be grafted to your relish.
Coriolanus, act ii., sc. 1.
- (18) *Suffolk*.
Noble stock
Was graft with Crab tree slip.
2nd Henry VI., act iii., sc. 2.
- (19) *Porter*. Fetch me a dozen Crab-tree staves, and strong ones.
Henry VIII., act v., sc. 3.
- (20) *Hortensio*. Faith, as you say, there's small choice in rotten Apples.
Taming of Shrew, act i., sc. 1.
- (20*)
How like Eve's Apple doth thy beauty grow,
If thy sweet virtue answer not thy show.

Here Shakespeare names the Apple, the Crab, the Pippin, the Pomewater, the Apple-john, the Codling, the Carraway, and the Leathercoat. Of the Apple generally I need say nothing, except to notice that the name was not originally confined to the fruit now so called, but was a generic name applied to any fruit, as we still speak of the Love-apple, the Pine-apple, &c. The Anglo-Saxon name for the Blackberry was the Bramble-apple; and Sir John Mandeville, in describing the Cedars of Lebanon, says:—"And upon the hills grown Trees of Cedre, that beu fulle hye, and they beren longe Apples, and als grete as a man's heved." (Cap. IX.). In the English Bible it is the same. The Apple is mentioned in a few places,

but it is almost certain that it never means the *Pyrus malus*, but is either the Orange, Citron, or Quince, or is a general name for a tree fruit. So that when Shakespeare and the other old writers speak of Eve's Apple, they do not necessarily assert that the fruit of the temptation was our Apple, but simply that it was some fruit that grew in Eden. The Apple (*pomatium*) has left its mark in the language in the word "pomatum," which, originally an ointment made of Apples, is now an ointment in which Apples have no part.

The Crab was held in far more esteem in the sixteenth century than it is with us. The roasted fruit served with hot ale (4 and 5) was a favourite Christmas dish, and even without ale the roasted Crab was a favourite, and this not for want of better fruit, for Gerard tells us that in his time "the stocke or kindred of Apples was infinite," but because they were considered pleasant food. Another curious use of Crabs is told in the description of Crab-wake, or "Crabbing the Parson," at Halesowen, Salop, on S. Kenelm's Day (July 17), in Brand's "Popular Antiquities" (vol. i., p. 342, Bohn's edition). Nor may we now despise

the Crab tree, though we do not eat its fruit? Among our native trees there is none more beautiful than the Crab tree, both in flower and in fruit. An old Crab tree in full flower is a sight that will delight any artist, nor is it altogether useless; its wood is very hard and very lasting, and from its fruit verjuice is made, not however much in England, as I believe nearly all the verjuice now used is made in France.

The Pippin, from being originally a general name for any Apple raised from pips and not from grafts, is now, and probably was in Shakespeare's time, confined to the bright-coloured long-keeping Apples (Justice Shallow's was "last year's Pippin,") of which the Golden Pippin ("the Pippin burnished o'er

with gold"—Phillips) is the type. It is not easy to identify the Pomewater (No. 15). It was highly esteemed both by Shakespeare ("it hangeth like a jewel in the ear of *Calo*,") and many other writers. In Gerard's figure it looks like a Codling, and its Latin name is *Malus carbonaria*, which probably refers to its good qualities as a roasting Apple. The name Pomewater (or Water Apple) makes us expect a juicy but not a rich Apple, and with this agrees Parkinson's description:—"The Pomewater is an excellent, good, and great whitish Apple, full of sap or moisture, somewhat pleasant sharp, but a little bitter withall; it will not last long, the winter frosts soon causing it to rot and perish." It must have been very like the modern

Lord Suffield Apple.

We have no such difficulty with the "dish of Apple-johns" (10 and 11). "The Deusan (*deusans*) or Apple-john," says Parkinson, "is a delicate fine fruit, well relished when it beginneth to be fit to be eaten, and endureth good longer than any other Apple." With this description there is no difficulty in identifying the Apple-john with an Apple that goes under many names, and is figured by Maund as the Easter Pippin. When first picked it is a deep green and very hard. In this state it remains all the winter, and in April or May it becomes yellow and highly perfumed, and remains good either for cooking or dessert for many months.

The Codling (2) is not the Apple now so called, but is the general name of a young unripe Apple.

The "dish of Carraways" (12) is by many supposed to be a dish of Carraway seeds, which I should think most improbable, or of cakes made of Carraways, which is possible, but looking at the context I have little doubt that it refers to the Carraway or Carraway-russet Apple, an excellent little Apple, still so called, that seems to be a variety of the Non-pareil.

The "Leathercoats" H. N. E.

(12) are the Brown Russets.

TROPICAL PARASITES.

(RAFFLESIA ARNOLDI).

THE RAFFLESIAS, of which three or four kinds are found in Java and Sumatra, are singular parasitic plants, we were going to say, but in reality they have neither stems nor leaves, the only evidence of the plant on its first appearance being a rounded bud, the size of a marble, protruding through the bark of a trailing *Cissus*, and which, after gradually enlarging for a

Rafflesia Arnoldi.

month or two, attains the size of a medium-sized Cabbage, and finally expands its five thick, warty, wax-like petals, forming a flower from a foot to a yard in diameter. These plants, so different in structure, appearance, and habit of growth from any other parasites, were first made known in 1818, when Sir Stamford and Lady Raffles, Dr. Arnold, and others discovered *R. Arnoldi* during one of their tours in the interior of Sumatra, and on descriptions and drawings being sent to this country, Robert Brown named the plant in honour of its discoverers. Several other species have since been found, but *R. Arnoldi* still remains the largest and most singular. In colour, the flowers are yellow, flushed here and there with pink, the petals being marbled with lurid purple, and the whole flower exhales a foetid odour by which insects are attracted to it, as in the case of *Stapelias*. The flowers remain open three or four days only, and then gradually collapse and decay. Another species—*R. Rochussenii*—was discovered in Java in 1850 by MM. Teysmann and Binnendijk, and this plant was, a year or two later, cultivated—I believe successfully—in the botanic garden at Leyden. B.

THE FRUIT GARDEN.

INSIDE *v.* OUTSIDE VINE BORDERS.

An impression prevails amongst some cultivators that Vines, the roots of which are altogether confined to inside borders, are shorter-lived, or at least sooner exhausted than those, the roots of which are allowed to ramble outside at will; but my own opinion is that the matter is entirely a question of management. If well supplied with food and moisture, inside borders for early Grapes are certainly to be preferred; they may be composed of richer materials—especially in the way of top-dressings—than would be desirable or even safe with borders exposed. I have always adopted this plan in preference to using strong liquids too freely, as there is a possibility of the latter, if given in excess, affecting injuriously the colouring of Black Grapes. Any one starting with the idea that inside borders require no more care than outside ones, or, who from the force of habit or the influence of the rule of thumb, treat them in the same way as they are often managed when in connection with houses where the Vines have both inside and outside root-space would, I fear, before long see reason to regret ever having come to such an erroneous conclusion; but the result would only show the necessity there is for forming a correct estimate of the different conditions under which the two are placed. It is nearly twenty years since I planted a number of Black Hamburgs and Muscat of Alexandria Vines in a brick-built pit inside a small forcing-house: the Hamburgs occupied the cool end of the house, and the Muscats the warmest position, and were at first planted one Vine to each rafter. After the lapse of two or three years, I encouraged the two strongest (a Hamburg and a Muscat) gradually to extend, removing the supernumeraries, as the two permanent Vines required the space, until in a short time they filled the house. As this extension was progressing, I could see a marked development in their strength, with a corresponding improvement in the quality of the fruit. The border or pit was altogether above the ground-level, and not more than 6 ft. wide. Stones to the depth of about 6 in. were placed in the bottom, and the roots could not by any possibility get out, being bricked in on all sides. The soil was not quite of the description that I should have chosen under other circumstances, but as it was to carry out an idea of my own, I did not feel justified in using the best turfy loam (which, by-the-by, was somewhat difficult to obtain); therefore the border was made up of a variety of substances, including the clearings from the rubbish-heap mixed with wood-ashes and burnt earth, and there was, I remember, rather more than the average number of stones, pieces of brick, oyster-shells, and materials of that character; this mixture, however, helped to keep the rich border open and porous, and perhaps was of no slight assistance in keeping the Vines in health under the rich top-dressings and the delugings with water that the border frequently had. There was no bottom-heat, but, as already mentioned, the border was above the ground-level, and there was a stack of hot-water

pipes close to the wall of the pit which would furnish a small degree of warmth, and the border was always watered with tepid water, so that its temperature would not be much below the mean average of the atmosphere. During the time of my stay there, the Vines continued to bear good crops of well-finished fruit; the Muscats especially were better than we had elsewhere. Eight years ago when I came here (Ramsey Abbey) a demand having arisen for early Grapes, and having fresh in my mind my previous experience, I adopted the same system of planting out Vines in a narrow brick pit, inside a lean-to house, instead of growing them in pots, which would have been the only other alternative. The root-space is very small, not more than 4 ft. wide, in fact, it might almost be called an amplification of the pot system. I may say I am rather partial to growing Grapes in pots, and generally grow a few fruiting canes most years, but for quality and quantity, with economy of labour, the potted Grapes with me do not equal those planted in the brick pit. There are two pipes under the bed for bottom-heat; this was an arrangement that was made for another purpose, otherwise in so confined a space I am not quite convinced of their necessity; the pipes, however, are never allowed to get more than comfortably warm, but of course even this must raise considerably the temperature of the bottom of the border. The main objection to hot-water-pipes under a Vine border is they have a dangerous tendency to dry the border too much, and the evil may exist for some time without its being suspected, and unless some provision is made for moistening the bottom of the border other than the customary one of pouring water on the top, the chances are some day a sudden difficulty may arise with the crop. I believe the best plan (and the one I adopt) is to fix earthenware pipes at intervals with one end resting on the rubble on the bottom of the border, and the other projecting an inch or two above the soil at top, and once a week or so to pour water liberally down, varying it occasionally with liquid manure. Bottom-heat from hot-water pipes skilfully managed will do no injury, but the good they do appears to me somewhat doubtful, *i.e.* in connection with brick pits raised above the ground-level in the atmosphere of the house, which is the only way I have yet had an opportunity of trying it; at any rate, I have had under similar circumstances as good Grapes without as with their use.

In the management of the Vines planted out in the way described, I consider there is a great advantage in training in a young rod or two wherever there is sufficient space without unduly crowding the foliage, and, after the fruit is all cut, remove a similar number of old ones, so that there are never any bearing rods more than three years or so old. I attach some importance to this as a means of keeping up and perpetuating vigour, and some kinds, such as Buckland's Sweet-water, bear best on young rods. With borders so limited in size it is a very great advantage (I had almost said a necessity) to remove as much of the surface-soil as possible; of course, as the border is full of roots, some disturbance of them must take place, but the work is done as carefully as possible, and the Vines take so kindly to the rich top-dressing, and derive so much benefit from it that I have never any hesitation or feel any compunction in removing as much of the old soil as possible, and as the two Vines that now fill the space are located one at each end, with the branches trained horizontally, I occasionally (perhaps once in three years) remove the border for a space of several feet in the centre, and fill in with fresh turfy loam and manure. The conclusion I have drawn from my grubbing amongst Vine roots is, that if the work be carefully and quickly done, they do not seem to resent this interference; on the contrary, when growing in a limited root-space, much good will result therefrom. Taking a general view of this question, if I had an early Vinery to plant now, I should certainly prefer planting inside the house in a border surrounded by brickwork; and if I had the option of a couple of hot-water pipes I should certainly accept them, feeling convinced that I could prevent them doing harm, although, as I have already remarked, the experience I have had with them so placed has not strongly impressed me with their being a necessity; but the truth is, I have faith in the utility of bottom-heat when rightly applied, rigidly watched, and proper precautions taken against over-dryness at the bottom.

A lack of moisture is the main cause of inside borders failing to attract and keep possession of the roots, and when once a border in such a position becomes thoroughly dry, it is a very difficult matter to moisten it. I believe, also, with small early houses and circumscribed borders, that the fewer Vines there are in proportion to the size of the house, and the more individual freedom of growth is encouraged, the better both for their productiveness and long living.

Since writing the above THE GARDEN has come to hand, and I have read Mr. Grieve's excellent remarks on the same subject, and with which in the main I entirely agree.

E. HOBDAV.

MELON CULTURE FOR AMATEURS.

THE inexperienced generally shun Melon culture as being a rather uncertain speculation, though they may be very successful perhaps in Grape-growing or Cucumber culture, both of which require just as much skill and attention, if not more than the Melon. The Melon is a most desirable summer fruit, and if obtainable would, we have no doubt, be more appreciated and generally used than even the Pine-apple. I shall, therefore, endeavour to explain, for the benefit of those who have not the usual appliances—in the shape of pits efficiently heated—at their command, how they may grow Melons by similar means. In the first place, it is necessary to state that, except under peculiarly favourable circumstances indeed, it is hopeless to think of growing the Melon in the open air in this country with any certainty of success, even with the assistance of hand-lights or cloches, in the way these are employed for Ridge Cucumbers and similar plants. Hardy varieties, so called, are recommended, which are said to succeed under such conditions; but we do not believe in them any more than we do in the culture of the Pine-apple out-of-doors. The Melon, in a usual way, requires a considerably higher temperature than we often experience in this country, for a period of four months at the least from the time the seed is sown, to produce ripe fruit, some idea may therefore be formed how little likely success is to attend any attempt at open-air culture; it may, nevertheless, be grown to perfection between the beginning of April and the end of September in a common glass frame, assisted by a moderate-sized hotbed, composed of materials which are within the reach of those who are possessed of either horses or cows.

The Hotbed and the Frame.

The frame should be made of good deal or planks, and should be 12 ft. long by 6 ft. wide, 2 ft. deep at the back, and 18 in. deep in front, and have three sashes. This is a convenient size, and it is better to have such portable structures, and more of them, than one or two very unwieldy ones. If the frame be made at home, the sides and ends should be made in separate pieces, with bolts and holes for securing them together when wanted; and at other times the frame can be taken to pieces and stored away in small compass. Some people find it considerably cheaper and more convenient to buy such things than to make them themselves. The hotbed is the great difficulty with most amateurs—not the finding of the material so much as the making and management of the bed, which however is more an imaginary than a real difficulty. The secret of the matter consists in making the bed right at first, and not putting it together a few days before the Melons have to be planted, as under such circumstances success cannot be expected. For a frame 12 ft. by 6 ft., a bed 14 ft. by 8 ft., and at least 2½ ft. deep after being well trodden, will be required. This area will allow a foot margin all round the frame, and the depth will be sufficient to sustain the required bottom-heat throughout the summer. The site for the bed should be sheltered, and it should have an open exposure to the south, in order that the frame may receive the sun's rays as long as possible every day; and it should not therefore be placed where it will be shaded by trees or walls from the morning and afternoon sun. This is an important point and one frequently overlooked. It is not by any means enough that the frame gets the sun about noon only; it must have it all day. If it be necessary, for the sake of appearances, to place such structures out of sight among the bushes or amongst

trees, we should say then, do not attempt Melon culture at all, for success is, under such conditions, extremely doubtful. The making of the hotbed is a very trifling matter, for a man may do all the work about it in a few hours; but the expense of the materials is a consideration to some people, who forget that the hotbed comes in the following year as a fund of excellent manure, suitable for almost any gardening purpose, and it may also be used instead of fresh leaves for tempering the rank litter for the next hotbed. We are in the habit of using old hotbeds for this purpose annually; Melon beds may, therefore, be said to cost only the trouble of making. For a kitchen garden several acres in extent, and for many flower beds and borders, we are allowed only the stable litter and manure; but nearly the whole of this has to do duty first as Mushroom beds and hotbeds for a variety of purposes, before it can be used on the garden ground. It will be necessary to begin making the hotbed three or four weeks before it is wanted. About three good cart-loads of litter will be required for a bed of the dimensions given. If it be from the stable, it must be taken as it comes, long and short together; but if from the farmstead heap, it is better to shake the rank cow manure out of it, and take the moist straw only, if horse-droppings cannot be had with it. These are always to be used with the litter if procurable, particularly if dead vegetable refuse has to be mixed with the litter instead of fresh leaves. The litter and leaves should be deposited for preparation near where the bed is to be erected; and if leaves cannot be procured to mix with the litter—and equal quantities of each will be required—then some substitute must be found. Old decayed hotbed material is the next best to leaves, and, failing either, any available decayed vegetable refuse may be employed, such as old Pea or Bean haulm, Potato tops, and the refuse vegetables from the kitchen garden generally, which might be saved for the purpose. Sawdust may also be employed—in fact, anything that is likely to ferment moderately. The stable litter is the principal thing, but the hotbed cannot be made of it alone, for it would be too hot, and the heat would soon subside. What is wanted is material to moderate the fermentation. If stable litter be plentiful and leaves scarce, more of the former may be used, and to prevent violent fermentation, soil, turf, and such like may be mixed with it at the rate of about one-fourth. Leaves themselves make an excellent summer hotbed for Melons if the bed be made 3 ft. or 4 ft. deep, but they are generally more difficult to procure than the litter. Leaves alone seldom heat to a higher temperature than 80° or 90°, and a good body of them is required to sustain that figure for a long period; but stable litter mixed with droppings will heat up to 150° or more. Now, for Melons the hotbed temperature will require to be about 85°, and the cultivator will therefore be able to judge what proportions of the different materials, according to their kind, he will require for the purpose; of course, if the litter be much decayed, it will not ferment so much, and the removal or addition of the droppings will make a great difference. One thing we must caution the reader against, and that is the use of newly-cut, short Grass; it ferments very violently and quickly, and subsides as fast, and is very unsafe for such purposes, though we are aware it is commonly used by amateurs, and often with disastrous results. Whatever materials are employed, they must be thoroughly mixed together twice or three times at intervals of ten days or a week, and well watered, if dry, at the same time, but it must not be trodden at this stage, and if the heat be pretty strong in the heap just before it is made into a bed, it is a good sign. The bed should not be constructed in a slovenly matter, but built as methodically and squarely as a hay-stack, or even more carefully, and it will be sure to stand well and not fall to pieces; it must also be trodden with the feet as firmly as possible as it is built, and it should be begun and finished in the same day. A thermometer should be inserted in the bed after it is finished, and as soon as the temperature has subsided to 100° or thereabouts, and is observed to be on the decline, the frame may be set on and filled with the soil.

Soil.

The materials suitable for a Melon bed are very simple. If we had our choice we should perhaps prefer good, half-rotted, turfy loam, for a Melon-pit, and for the same reason

that we should prefer such a soil for Potatoes; but it is by no means indispensable for either. The Melon will grow in any good garden soil that is not too heavy nor yet too light. As a rule, soil in which ordinary vegetables grow will well suit it, and the more loam there is in it the better; but it must not be too heavy. We have often run out of turfy loam procured from the pastures for our Melon beds, as they take much soil; but we never ran short of a soil so long as we could sift what we wanted from the kitchen garden quarters, taking the top spit, and getting it on a dry day if possible, and we could not say that our crops were ever really either better or worse in consequence. We would recommend the amateur, therefore, to use turfy loam alone, after it has been laid up in heaps till the fibre is dead, if he can get it; and if not, to use the soil from his Cabbage or Potato quarter. Our Melon-beds are heated by hot-water pipes underneath, and have not to be removed periodically as in the case of beds; consequently we just dig the beds over, add a good dressing of fresh soil, and plant at once without the slightest misgivings as to the success of the crops.

Sowing and Planting.

The middle of April or beginning of May is soon enough to plant out Melons in a frame under the circumstances here contemplated. To plant them sooner would entail extra appliances in the shape of linings of litter applied frequently to keep the heat of the bed up; whereas, after the beginning of April these can be almost dispensed with. It is needless to get the hotbed ready long before the plants are fit to put into it, unless there is no other convenience for raising the seeds, in which case it should be prepared three weeks earlier. If, however, the plants can be raised somewhere else than in the bed, it is better; and in such a case the seed should be sown when the fermenting material gets its first turning, and they will be ready for planting just about the time the bed is ready, if all have gone on well. A dozen good seeds or more should be sown to ensure a sufficient number of plants; a 6-in. pot will hold them all, and it should be well drained and filled with fine, light soil, in which the seeds should be sown and covered with a little fine soil. The pot should be plunged up to the rim in a bottom-heat of 80° or 85°, and no water should be given for three or four days after sowing, or until the seeds are seen to be pushing through, when the soil may get a soaking with tepid water, and be kept moderately moist afterwards. When the plants have made their first rough leaves, they should be shaken carefully out, and potted off singly in 4-in. pots, using a light, fine, and open soil, and potting them right up to their collars, and returning them to the hotbed. From this time also—in fact, from the time they appear above the soil—they must have an atmospheric temperature of from 65° to 70° at night, with a rise of from 5° to 20° during the day, accordingly as the weather is clear or dull, and treated to genial temperature generally, but not kept too damp overhead. The plants under this treatment, and if they have been kept near the glass, will grow rapidly, and will be ready for planting out in the bed by the time the frame is ready for them. A week or so before planting, 9 in. of soil, of the kind before described, should be placed in the frame in the form of a ridge, rounded on the top a little, or it may be spread out perfectly flat in the same slope as the frame. When the soil has got warm, the Melons should be planted—two in the centre of each light—and watered; and if they have not been topped before, that operation should be performed now, leaving only two or three good leaves, from the axils of which the bearing limbs will proceed.

Training and General Treatment.

We have recommended two plants to be planted in each light, which may appear close to experienced cultivators, but it is the best way to insure a regular crop with the inexperienced. The plants are placed back to back, and one is trained towards the back of the frame, and one towards the front. Two limbs only must be trained from each plant, in the form of a V; that will be one leg towards the corners of each light. Before they have travelled so far, however, say more than 3 ft., they must be stopped by having their points pinched off, and both limbs of the same plant must be stopped on the same day, even

though the one be shorter than the other. This is to insure the production of flowers on each limb at the same time, and a simultaneous "set," for it is a peculiarity of the Melon that if one fruit be set a few days before the others, that fruit will swell and the others will not. For this reason the methodical pinching and training of the Melon is an important matter. Very frequently the later-set fruits will just stand still when about the size of small marbles (unless they turn yellow and drop), and then begin to swell when the fruits that got the lead have ceased swelling and begun to ripen; this we have noticed often. After pinching, each limb will produce side shoots along the stem, all of which must be pinched off at the first joint, and kept pinched, except two or three on each side near the extremity of the limb; these must be left, and pinched in their turn, two joints forward or one joint beyond the fruit, which is likely to appear at this stage, either on the first laterals or the sub-laterals; and when the flowers expand they must be impregnated with a camel's-hair pencil from the pollen of the male flowers, which always appear in abundance. Two days will suffice to show whether the fruits have set well or not, and in a few days more the number may be reduced to three or four to each plant; it is always well to set plenty of flowers the first chance to ensure a crop. After this the pruning and training consist in allowing the bearing shoots to grow, and thinning the others out by turns, so as to prevent overcrowding; but the fewer pegs used the better. As regards airing, it is a good plan never to shake off air altogether, unless when the night temperature falls below 70°, and it should be gradually and sufficiently increased during the day with sun-heat to prevent the temperature rising above 86° or 90°, but reduced at a quicker ratio in the afternoon in order to shut in sun-heat against cold nights. Shading should never be used, except for a couple of days after the plants have been put in, and syringing once a day, and that on sunny afternoons only, when the frame is shut up, will be quite enough. The bed should be watered thoroughly with tepid water when it appears to be dry to the touch, but hotbeds do not require such frequent waterings as beds placed above hot-water pipes.

"Field."

BULLFINCHES AND FRUIT-BUDS.

BULLFINCHES are once more at their spring work of bud-thinning, or rather the absolute clearing of Plum trees, and where these birds abound, they are destroying the pistils or nectaries of Apples and Pears where the blossoms are partially opened. I observe that they treat different buds with different degrees of attention. Plum-buds never receive more than one peck, which is invariably of sufficient force to drive the bud to the ground. They peck so rapidly that I have noticed thirty buds fall in a minute; on a careful examination of the fallen buds, a small part of the pistil appears removed, and occasionally a piece of the ovary. Is it for this infinitesimal morsel that the buds are knocked off? Or do the bullfinches become so fastidious in their tastes that, like the gods of the ancients, they feed only on nectar, and destroy the fruit-buds in their eagerness to obtain it? Saffron was formerly cultivated extensively for the sake of the dried pistils of the flowers—and are whole crops of fruit to be sacrificed to fatten bullfinches and others of the feathered tribe on the tips of pistils, the bases of ovaries, or the sweets of nectar? If so, their songs may well be sweet and their breasts rosy red. But their beauty and their song may also be purchased too dearly. I wish some student of ornithology would investigate this matter and inform fruit cultivators why bullfinches destroy the buds with such celerity and apparently for such very limited food results. Again, they are much longer in their attacks on Pear blossoms than on those of Plums, scooping the former out rather than knocking them to the ground; moreover, they seem to eat much more of them, and hence they destroy fewer in the same time. I may here remark that I do not believe in the insect theory. The bullfinches seldom, if ever, eat insects; besides which, I have never been able to discover any insects in the buds of Plums and Pears that they were determinately destroying. The suggestion that the birds are in any sense or degree the friends of fruit-growers must be propounded in utter ignorance of the enormity of the evils and losses they inflict: facts, losses, crosses, failures innumerable, all point to a contrary conclusion. The bullfinch, notwithstanding his winning ways, his beauty of plumage, and sweetness of song, is the arch enemy of the fruit cultivator in the spring, and often destroys more crops in the bud than the stinging frosts or the most withering winds.

D. T. FISH.

SOCIETIES (AND) EXHIBITIONS.

ROYAL BOTANIC SOCIETY, REGENTS PARK.

MARCH 21.

THIS was the Society's first exhibition this year, and the main difference observable on contrasting it with the spring shows of former years was the nearly total absence of stove and greenhouse plants, and the preponderance of more easily cultivated bulbs and flowering decorative plants. Hyacinths, as shown by Messrs. Veitch & Sons and by Messrs. Barr & Sugden, were in excellent condition; as also were Tulips, Narcissi, and other early spring flowers. New plants were scarcely so numerous as usual; most of those shown on this occasion have been exhibited and certificated elsewhere, and as they have already been described in THE GARDEN, we omit them on this occasion.

Certificates.—These were awarded to the following new plants and florists' flowers:—

Panax laciniatum (Veitch and Williams).—A graceful little stove shrub, which will be useful as a fine-foliaged plant. Its leaves are rather finely cut, and are of a fresh green colour, the whole plant being evidently of a vigorous habit of growth.

Alsophila philippinensis (Veitch).—A very stately-habited Tree Fern, having ample dark green fronds nearly 4 ft. in length, the pinnae being of great substance, and curled slightly so as to give the fronds a crispulate appearance. The plant is quite distinct, and, being a strong grower, merits culture either for decorative or exhibition purposes.

A. pycnoptera (Veitch).—Like the last-named species this is robust in habit, the fronds being ample and of great substance; in colour it is a light, fresh green, forming quite a contrast in this respect to that of *A. philippinensis*.

Cyclamen roseum grandiflorum (Edmonds).—A large-flowered form of *C. persicum* with petals of a rich rosy tint, the ring at the base being deep crimson.

C. persicum, White Swan (Edmonds).—A large-flowered form similar to the last in shape and size, but of a pure white colour throughout—a desirable variety.

Nephrolepis Duffii (Veitch).—A dwarf and elegant-habited Fern, having constricted dark green fronds curiously crested at their apices as in some *Lastreas*. It appears to be vigorous in habit, and will be a welcome addition to decorative Ferns.

Adiantum æmulum (Veitch).—A pretty Maiden-hair Fern, apparently as vigorous as *A. cuneatum*, and not unlike *A. assimile* in habit, but having more rhomboidal or diamond-shaped minor divisions. The fronds are light and graceful in outline, and of a fresh green tint.

Croton, Earl of Derby (Veitch).—A robust-growing plant belonging to the *C. trilobum* section, and having bold, halberd-shaped leaves of a dense green colour boldly blotched with golden-yellow. It is a plant which cannot fail to be popular when more plentiful.

Hyacinth, Orange Queen (Veitch).—A striking, rosy-crimson-flowered single variety, forming an excellent spike, and well deserving a place in every collection.

Hyacinth, globosus (Veitch).—A strong-growing variety, bearing a stout spike of double buff-tinted flowers nearly 2 in. in diameter.

Hyacinth, Queen of Lilacs (Veitch).—A distinct and free-growing kind, bearing a stout, erect spike of soft lilac or purplish flowers.

Hyacinth, Marquis of Lorne (Veitch).—A vivid, single-flowered, blue variety, the flowers of which are arranged symmetrically on a stout spike.

Pultenæa rosea (Rollisson).—A bushy little Pea-flowered plant, not unlike a Heath in general appearance, bearing tufts of rosy-lilac flowers at the ends of the young branches. It is a native of Mount William, one of the peaks of the Grampian chain in the colony of Victoria; and as it is found at an altitude of 5000 ft. it is supposed to be nearly hardy, it will therefore make a pretty cool greenhouse shrub.

Cinerarias (James).—Six varieties were selected from Mr. James' batch of seedling Cinerarias as being worthy of floral certificates, all of which were of dwarf and compact habit, and furnished with large and well-formed flowers arranged in dense, shapely clusters. Of these, one named *Mary*, a rosy-lilac, nearly perfect flower, was decidedly the best. Mrs. F. Watson is a large rosy crimson, having a distinct white ring around the eye. Thomas Winter is a good purple form; as is also the rich rosy-crimson Thomas Stent. Purple Gem is a large violet-purple flower, the colour of which is delicately shaded towards the narrow white ring which surrounds the eye. Jane is a good rosy-lilac; and Mrs. Winter a rich, dense purple flower.

Miscellaneous Plants.—A select group of flowering and fine-foliaged plants came from Messrs. James Veitch and Sons; among them we noted *Philodendron Haltonianum*, a kind with undulated, trilobed, dark green foliage; several new *Crotons*; *Dendrobium amethystoglossum*, a rare species bearing clusters of white amethyst-tipped flowers on leafless pseudo-bulbs 2 ft. in length. In the same collection were likewise *Alsophila philippinensis* and *A. pycnocarpa*, both stately and distinct Tree Ferns with ample fronds, and a dwarf, attenuated, crested *Nephrolepis* named *Duffii*, which is likely to please all Fern growers, as is also the delicate, grass-green foliaged *Adiantum æmulum*. The Brisbane Lily (*Eurycyles anstraliasica*) to which we have before alluded, was conspicuous, as was also the harsh-looking *Masdevallia chimera*. Messrs. Veitch also

sent a perpetual-flowering Clove Carnation named Tom Thumb Scarlet, a kind dwarf in habit, and bearing bright orange or vermilion-scarlet flowers on stems scarcely 6 in. in height. A showy group of forced Clematises came from the same establishment, the most conspicuous varieties being Miss Bateman, a silvery-white, eight-rayed flower; Stella, lilac purple; Lady Londesborough, lilac; and Marie Lefebvre, a large, eight-rayed lilac flower with a bluish-purple stripe down the centre of each sepal. This group was tastefully associated with fresh green specimens of the Japanese Cut leaved Maple. A large collection of Hyacinths shown by Messrs. Veitch deserved more than a passing notice, for, in addition to the plants being remarkably well grown, the spikes generally were of large size and well finished; the tasteful way, too, in which the colours were blended, and the finishing off of the whole with a top-dressing of fresh green Moss distinguished this collection from all others. It included a selection of all the best varieties in cultivation. Among the newer kinds we noted *Reine de Naples*, a vivid rosy-crimson, with a stout and well-formed spike; *Purity*, white, large both in flower and spike; *John Bright*, good single blue; and *Anton Belle*, a distinct variety, of a soft rosy-lilac colour, the flowers, which are well shaped, being remarkably well arranged on the spike. The best twelve Hyacinths in the nurserymen's class came from Messrs. Barr & Sugden, who had the following kinds: *Czar Peter*, light blue; *Grandeur à Merveille*, creamy-white; *General Havelock*, black-purple; *Macaulay*, rose; *Leviathan*, white; *Haydn*, purple; *Vuurbaak*, crimson; *De Candolle*, lilac-blue; *King of Blues*, dark blue; *Bleu Grand*, light blue; *La Grandesse*, pure white. All these were single kinds, having bold, well-developed spikes, supported by stout, fresh green foliage. Mr. James Douglas, who was first in the amateurs' class for twelve Hyacinths, had *Ida*, single yellow; *Vuurbaak*, crimson; *King of Blues*, dark blue, very good spike; *Grandeur à Merveille*, flesh; *Baron Von Tuyll*, dark blue; *Fabiola*, light red; and others: all good. In the open class for Hyacinths, Mr. Douglas was first with well-grown spikes, Messrs. Barr & Sugden being second, and Messrs. Cutbush third. The first prize for twelve pots of Tulips was obtained by Messrs. Barr & Sugden, who had the following varieties:—*Vermilion Brilliant*, scarlet and yellow; *Proserpine*, purple; *Joost Van Vondel*, crimson, white, and cerise; *Gresdeline*, rosy-purple, edged with straw colour. In the amateurs' class for Tulips, Mr. Douglas was first with *White Pottebakker*, white; *Van der Neer*, purple; *Vermilion Brilliant*, scarlet and yellow; and *Keizer Kroon*, scarlet edged yellow. Narcissi in pots were very effective, the first prize being awarded to Messrs. Barr & Sugden; the best six pots of Lily of the Valley came from Mr. J. Douglas. Mr. G. Wheeler obtained the first prize for twelve miscellaneous stove and greenhouse plants, the most remarkable specimens being *Phalaenopsis Schilleriana* and *Eriostemon densiflorum*. Mr. W. P. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham, sent twelve well-grown pots of bulbous plants, to which the first prize was awarded, the most effective plants being *Amurillus Distinction*, *Triteleia uniflora*, *Scilla sibirica*, and blue and white *Muscari* of different kinds. Mr. R. Dean was first in the class for hardy Primroses with good plants of *Primula denticulata*, the larger and darker-flowered *P. purpurea*, an effective kind, with flowers in dense, globular heads, well elevated on stout scapes; the others were lilac, crimson, yellow, and double forms of *P. vulgaris*. The best six Chinese Primulas came from Mr. James, all fairly well-grown specimens, the colours of which were white and purple. Mr. B. S. Williams sent a large and well-arranged group of Orchids, Palms, Ferns, Agaves, and other decorative plants in excellent condition. Well-grown plants of *Dielytra spectabilis* came from Messrs. J. Carter & Co. Among *Dentzias* the best were sent by Mr. J. Douglas, of Loxford Hall, Hford, whose specimens consisted of well-grown old plants, 3 ft. or more in height and nearly as much in diameter, the sticks around which they were trained being completely hidden in fresh green foliage and snow-like masses of flowers and buds. Mr. James, of Redlee, Isleworth, contributed smaller but well-bloomed plants. The best group of twelve Cyclamens also came from Mr. James, who showed remarkably robust and well-bloomed plants in 32-sized pots, each bearing from 50 to 150 or 200 flowers, the colours of which were bright and distinct. Mr. H. Little was first in the amateurs' class for six Cyclamens, each of which was furnished with about 200 blooms, but much smaller than those in the last-named class. Mr. Charles Turner sent his new perpetual-flowering Carnation, *Rose Perfection*, in good condition, and also a stand containing a dozen flowers of other varieties, among which we noted *C. Gloire de Lyon*, scarlet; *Mazeppa*, rose-flaked scarlet; and *Fairy Queen*, a small white flower striped with rose. Mr. Turner, who was the only exhibitor of pot Roses, gained the first prize with well-grown specimens 4 ft. through, the sorts being *Alfred Colomb*, rosy-crimson; *Celine Forestier*, yellow; *Paul Verdier*, rosy-purple; *Le Mont Blanc*, creamy-white; *Marquise de Castellane*, a full bright rose; and the ever-welcome *Souvenir d'un Ami*, with globular, flesh-tinted buds and flowers. Mr. Turner also obtained a first prize for six well-flowered Azaleas, each about 3 ft. high and 2 ft. in diameter. The most distinct and effective sorts were *Stella*, scarlet flushed with purple; *Belle Gantoise*, blush; *Duc de Nassau*, crimson; and *Apollo*, white flaked with rose. In the amateurs' class Mr. A. Ratty, of the Hoo Gardens, Sydenham, was first with well-grown pyramidal plants. Messrs. W. Paul & Son, of Waltham Cross, sent twelve stands of cut *Camellia* blooms in very good condition. Among the varieties we noted *fimbriata*; *Princess Charlotte*, a white, elegantly-cupped flower; *elegans*; and others. Mr. James, gardener to W. F. Watson, Esq., Isleworth, sent a collection of well-grown seedling Cinerarias similar to those shown at the last South Kensington meeting. Messrs. Smith & Sons, of Dulwich, showed a stand of cut Cineraria flowers of good form and brilliant colour, to which we have previously referred.

ROYAL HORTICULTURAL SOCIETY.

MARCH 21.

At this exhibition, which was a very interesting one, nearly all the principal nurserymen showed collections of early flowering or new decorative plants. Messrs. Veitch & Sons had an extensive and well-arranged group of forced Roses, Clematis, Hyacinths, and a small group of new fine-foliaged plants, to several of which certificates were awarded. Mr. J. Wills showed some thirty remarkably well-grown specimens of his new seedling *Dracænas*, the most conspicuous of which were *D. terminalis* alba, *D. Carolettae*, *D. salmonæa*, and *D. Gladstonei*, all of which are decided improvements on existing kinds. A beautiful group of fine-foliaged and flowering plants, arranged for effect by Mr. Wills, was much admired, and was mainly composed of slender Palms interspersed with Ferns and other fine-foliaged plants, Azaleas, &c., the whole being fringed with creeping *Ficus*, *Isolepis gracilis*, among which pots of the sky-blue *Myosotis dissitiflora* or early-flowering *Forget-me-not* were placed with excellent effect. Sir H. Peek sent from Wimbledon House a choice and well-grown group of *Orethids*, among which we noticed a large-flowered plant of the beautiful *Odontoglossum Roezli album*.

First-class Certificates.—These were awarded to the following new and rare plants:—

Croton McArthurianum (Veitch).—A distinct and free growing variety of bushy habit, having broadly strap-shaped leaves curiously lengthened at their apices into tail-like terminations; their colour is a dark glossy green, variously barred or blotched with golden yellow, and here and there suffused with red—altogether a handsome stove shrub.

C. trilobum, Earl of Derby (Veitch).

Nephrolepis Duffii (Veitch).

Primula purpurea (Dean).—A robust and free-flowering plant belonging to the *P. denticulata* group, but with larger flowers and of a more decided purple colour. It is so distinct and effective that it will be welcomed in all collections of hardy flowers.

Cyclamen persicum, Ruby (H. Little).—A free-growing and profuse-blooming kind, bearing vivid crimson purple or rather ruby-tinted flowers. It will be useful for breeding purposes, and for contrasting with the white and rosy-lilac varieties in decorative arrangements.

Primula sinensis fl.-pl., Marchioness of Exeter (Gilbert).—A robust-growing plant, the specimen exhibited being 2 ft. 5 in. in diameter, and bearing 113 fully expanded flowers, and twice that number of unexpanded buds. This plant had been grown from a cutting inserted in April last, and was perhaps the finest specimen of a double-flowered Chinese *Primula* ever exhibited. The flowers are large and perfectly double, the colour of this particular variety being rosy-blush; but the strain varies in tint from pure white to carmine, some of the seedlings being very delicately flushed and speckled or flaked with rose.

H. P. Rose, Duchess de Vallambrosa (H. Bennett).—A robust-habited variety, evidently belonging to the same race as Captain Christy, which it somewhat resembles in form and habit. The colour is a delicate silvery-rose, inclining to bright salmon-rose in the centre.

Poinsettia pulcherrima plenissima (Veitch).—A now well-known plant, to which a certificate was awarded for the first time. It is a great improvement on the type, from which it differs in having a greater profusion of crimson-scarlet bracts, forming what is popularly known as a double inflorescence. It was described and figured in the pages of THE GARDEN last year.

Fruit and Vegetables.—Mr. J. Maher, gardener to C. Allbansen, Esq., Stoke Court, Slough, sent a box of Cucumbers named Maher's Eclipse, along black-spined variety; and the Hon. and Rev. J. T. Boscawen sent a shapely, white-spined, seedless variety of Cucumber, which he has grown for some years in his garden at Lamorran in Cornwall. Mr. R. Gilbert sent from Burghley a small winter Cabbage of good quality, two splendid dishes of Mushrooms from open-air beds, and Rhubarb, Seakale, and French Beans in excellent condition. Mr. Batten, gardener to Mrs. Willis Fleeming, Chilworth Manor, Romsey, sent a very good dish of the rosy Extra Early Vermont Potato, grown on the back shelf of a Vinery; the tubers were planted on Jan 1 in 7½ in. pots.

ROYAL HORTICULTURAL SOCIETY AND FELLOWS' PRIVILEGES.

HAVING reason to know, from conversation with numerous amateurs and others, that the lengthened correspondence which has recently appeared in the newspapers has tended only still further to mystify the public, and consequently to injure the Society even more than was previously the case, I venture briefly to direct attention to the following facts, hoping thereby to remove the doubts of many who will then be willing to come forward and aid by their subscriptions a Society which has done in the past, and is still doing, much valuable work:—(1) The Society is now, financially, in a better position than it has been for several years past, but its income is still most inadequate, and, with additional aid, it would be able to carry on its experiments, and maintain the efficient working of those committees whose labours have been, and are still, so beneficial to the public. (2) Besides other valuable work, competitive trials of great scientific and practical value have for years been carried on, and are still continued at Chiswick with the best results, whilst the reports in the horticultural papers are sufficient testimony to the thoroughly successful working of the Scientific Fruit and Floral Committees connected with the Society. The fortnightly shows are also a great success, even beyond the most sanguine expectations. (3) What is now required is to obtain an increase of Fellows and members,

and I think it cannot be too well known that those who wish to join the Society can do so on the following terms:—(A) By payment of one guinea per annum, which payment entitles the member to see the gardens at all times, including all shows, fêtes, conversazioni, and promenades, both at Chiswick and South Kensington, but without giving a vote at the meetings of the Society; or (B) by payment of two guineas a year, which entitles the Fellow to one yearly transferable ticket, admitting the bearer every day, and to all shows, fêtes, conversazioni, and promenades both at Chiswick and South Kensington, and enabling him to visit the shows at an earlier hour than the general public; also admitting the bearer with two friends on all ordinary days; to receive forty orders giving free admission to promenades on all days, excepting show and special days; to have the right of voting at all meetings, besides other privileges; or (C) by payment of four guineas a year, which entitles the Fellow to two yearly tickets, both of which are transferable, and which give the bearers admission every day and to all shows, fêtes, conversazioni, and promenades, both at Chiswick and South Kensington; to visit the shows at an earlier hour than the general public; to receive forty orders giving free admission to the promenades and on all days, excepting show and special days; the right of voting at all meetings; free admission to the reading room, besides many other minor privileges. (D) *Bonâ fide* head gardeners, on payment of 10s. 6d. annually, are admitted as members with the same privileges as amateurs who pay one guinea per annum. (E) There is now no entrance fee, and any one subscribing is in no way liable for any amount beyond the subscription for the year. I am surely not too sanguine in expressing a hope that throughout Great Britain, where the love of flowers is so universal, there are many who will be willing to come forward, and at so small a cost to themselves, to help to support a society which has done so much good in the past, and which I feel confident must, with efficient aid, have a very brilliant future. I venture to appeal on its behalf for such support, and shall gladly receive the names of any who are willing to become members; and I shall be happy to obtain the necessary signatures to the nomination papers, so as to save as much trouble as possible as regards election, &c.

March 20.

HARRY J. VEITCH, *Royal Erotic Nursery, Chelsea.*

GUINEA FELLOWSHIPS.

MAY I beg the favour of space for a last letter on Guinea Fellowships in the Royal Horticultural Society? The Council have adopted the guineas, but, alas, only to the extent of membership without a vote, instead of, as we asked, fellowship with a vote, as our one object has been to infuse good, new horticultural blood into the Society and so strengthen it. I need hardly say that the restriction renders the concession in this view worthless. I am told that it was considered if a vote had been given, so many persons living in the neighbourhood of the gardens would have become Guinea Fellows that the votes of those not on the spot might have been swamped. Taking the idea from a member of Council after the last general meeting, I suggested to the President that if the Council would give Guinea Fellowships with votes to those living outside the London postal district, I thought many good country horticulturists might be induced to come in. This was only on the principle that if you cannot get best you must try for second best, the Society having still its old heavy load of incumbrances on its back; but I thought that our Fellows would get horticultural consideration for their guineas, and that they would leave the Society. This proposal was not adopted. Some of your readers who have given their names as would-be Guinea Fellows ask what they ought to do. I think our best course is to go on quietly collecting names, and waiting, trusting to the chapter of accidents. The Council may re-change their policy. It is an unpleasant reflection: but for country horticulturists to give their guineas to the Society without getting a vote, would be, I think, merely to that extent to bolster up a state of things which the experience of now very many years has shown to lead only to constantly recurring seasons of discomfort and failure. The question is, as I have had to repeat over and over again, one of simple common sense. Every scientific society with head-quarters in London has more or less prospered, except the Royal Horticultural Society; there is no science with nearly as many friends as horticultural science. Every other scientific society (excepting the Zoological Society, with its show every day, and the position of which is essentially peculiar), trusts for its support to those interested in its object. The Royal Horticultural Society, except quite at its commencement, has never done so; surely it is a fair inference that if it followed the course of its sister societies in this respect, with the advantages of its wide sweep and more general constituency, it would become the most prosperous of all. It now only remains for me to thank you for the valuable space given to me, and to thank those good horticulturists in the country who have taken so much trouble in this matter; their work will assuredly bring fruit hereafter. Four years ago, when Guinea Fellowships were first mooted, their supporters were counted by tens; they now are by hundreds, including the best horticulturists of the country: when they come up next (with the gained experience) they should be by thousands. I ought perhaps to apologise for having put myself forward, but having served for many years in almost every office of the Society, I know exactly its requirements, and having time and means, knowing its past troubles, and seeing a remedy against future ones, it seemed that I ought (no one else having come forward) to undertake the work at first. Before long I became merely the mouth-piece of many of the best and most experienced horticulturists of the country, who urged me not to let the matter rest till the Guinea Fellowship was accomplished and the Society reconstituted.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

PEAR INSECTS.

(ANTHONOMUS PYRI).

PARIS is now suffering from a pest from which this country is happily free. From recent advices we learn that the larvae of the above insect are very active in destroying the fruit-buds of the Pear in the fruit gardens about Paris; as our correspondent says, it is even a worse enemy than the spring frosts, destroying the buds of whole trees at a time. We have an allied species in England (*Anthonomus pomorum*) which specially attacks the Apple tree; another which attacks the Cherry tree; a third devoted to the Bramble, and so on. The Pear tree species has not, however, we believe, been found in England. But twenty years ago Paris, too, was almost free from it. Boisduval, writing in 1867, says:—"For some years past this insect, which was formerly almost unknown in the environs of Paris, has become a perfect scourge for the Pear trees. Its appearance in our gardens, according to M. Forest, does not reach farther back than a dozen years." The perfect insect is a long-snouted weevil, about $2\frac{1}{2}$ lines in length. It winters in a torpid state in the crevices of the Pear tree. It awakes at the commencement of spring (beginning of March) couples and lays its eggs in the flower-buds, one in each bud, eating out a tiny hole with its beak to allow passage for the egg, which is hatched in about eight days. No bud containing a larva ever flowers; a blackish circle is formed at its base, and the bud itself ends by blackening, too, and drying up. The larva takes about a fortnight to reach maturity, and it then undergoes its metamorphose in the bud itself. This is just one of those cases in which combined action might do something to abate the mischief. It is obvious that, with a minute insect which in the perfect state has wings, and flies readily from tree to tree, it is not in that state that it can be attacked; but in the larval and pupal stages it is at our mercy, if we will take the trouble. The attacked buds are readily recognisable, and if every one were everywhere to pick them off from the trees in their own garden and burn them, the insect might be stamped out in a single season; but although that might be easy in a small garden with a few espaliers or trained wall trees, it would not be so easy in a large orchard where there are high and thickly branched trees. Still, there is no other remedy, and if every one made an effort, and all at the same time, it seems to stand to reason that the insects would be much diminished in number and kept within ordinary bounds. What is wanted just now in this country and in all other civilized countries—not only for this insect, but for hurtful insects generally—is a commencement of this system of stamping out. All that is needed is a knowledge of the right time to attack each insect, and simultaneous action in doing so. The latter is the real difficulty, and Government ought to undertake it.

A. M.

GRASS LAWN DEPREDATORS.—I have sent you what I take to be the larvae of the daddy long-legs, which have committed much damage in St. James's Park, the Embankment Gardens, and London Fields. Can you oblige me by suggesting an easily applied remedy?—G. H. [As you suppose, the grubs are those of the daddy long-legs. To destroy them I should be disposed to sprinkle the ground of the Embankment with Paris green (emerald green of our shops), and then water it. I have tried the experiment with the specimens sent, putting them in earth in a box, and next morning they were all lying dead on the surface. The price of emerald green is 1s. per lb., but a small quantity will go a long way.—A. M.]

SCILLA BIFOLIA ROSEA.—This rose-coloured form of one of our most attractive spring-flowering bulbous plants, is now in good condition in Mr. Parker's nursery at Tooting. Though not so showy as the blue-flowered Scillas, yet when associated with them it forms a pleasing contrast; and when plants of it are plentiful, and it can be had at a cheap rate, it will doubtless be appreciated.—C. S.

ANEMONE FULGENS FROM SEED.—In the extensive experiments made by Mr. Henry Vilmorin in the culture and propagation of this plant it was found that many of the seedling plants were not of the brilliant colour so remarkable in the true and finest strain, but of a red with a shade of brick in it. We have seen many of these plants which were carefully separated from the pure stock. They are singularly alike in hue, and manifest no tendency towards *A. stellata*. On the other hand, plants of the true colour are raised in this way, and sometimes remarkably fine ones, but seed is, nevertheless, not to be depended on for reproducing the plant in its finest form. Nor did any of these numerous seedlings ever manifest the slightest tendency to approach the broad-petalled *A. coronaria*. It must not be forgotten that there are here and there single forms of the old garden *Anemone coronaria* which are splendid in their brilliancy of colour, and there can be little doubt that one of these was the variety sent by Mr. Boscawen last week, and which is described on p. 225. Some of these forms deserve to be increased and widely distributed by nurserymen.—V.

THE PITMASTON PEAR.—This is, so far as I know, the finest Pear ever raised in England. The figure in no way over-praises the fruit, indeed, I have seen larger specimens. The flavour is in all ways excellent, and the flesh melting and tender as could be desired in a Pear. With this and the precious Doyenné du Comice we are now rich in the noblest Pears that could be desired for their seasons. Can any reader of THE GARDEN tell us a little more of the origin of the Pitmaston Pear?—ENQUIRER.

ASPARAGUS FORCING IN PARIS.—I have lately visited a very extensive establishment for the forcing of Asparagus in Paris, of which a few words may not be without interest to readers of THE GARDEN. In all about half an acre of glass is devoted to the culture, and a supply is obtained from early in September to the end of April. It is forced in three ways—in houses heated with hot water; in frames sunk in the ground and heated in the same way; and lastly, in frames plunged in warm stable manure. It appeared to be forced with equal success in each case, though the stable manure seemed to offer the simplest means. As usual here the frames are small—about 4 ft. wide; the roots are placed directly on the manure, not flat as they would be in the open ground, but packed as closely as possible, from 500 to 2000 roots—according to size—going under one light; a mere sprinkling of soil is placed over them. As a result, the shoots come up very thickly. The roots employed are strong and fine ones, three years from the seed; as many as five crops of roots follow each other throughout the autumn, winter, and spring in the same frame. The universal straw mat is used to cover the frames at night. A dozen persons were employed solely in gathering and "bundling" the Asparagus for market, so that the quantities gathered for use are considerable. All is done in the simplest and rudest manner, the securing of good crops being the only thing considered.—R. W.

SHOW OF COVENT GARDEN PRODUCE.—It is proposed to hold an exhibition of fruits, flowers, and vegetables in the Royal Horticultural Gardens, at South Kensington, the exhibits to be contributed by the salesmen and dealers in Covent Garden Market. The idea, which is a good one, originated, we believe, with Mr. W. Howard, who, in conjunction with Mr. A. F. Barron, has conferred with the principal market dealers, who agree to the project, and the exhibition is, we understand, arranged to take place on the 18th of April. When it is considered what a wealth of home-grown and imported fruits and vegetables is exhibited daily in Covent Garden Market, together with a profusion of the most tasteful wreaths, bouquets, and other floral decorations, the exhibition now proposed ought to be one of the most interesting ever held at South Kensington. This movement deserves all the more encouragement from the fact that whilst gardening generally has been steadily progressing, our exhibitions of garden produce have kept to the old beaten track. We have looked on the "twelve stove and greenhouse plants," the "six Orchids," and the "nine fine-foliaged plants," until we are weary of the name of horticultural shows, in which the only innovation of recent years has been the classes set apart for interesting hardy flowers. Let us, therefore, hope that this show of Covent Garden produce will meet with the amount of encouragement which it deserves.—B.

FIG TREES AT ARGENTEUIL.—The Fig trees so well and extensively grown round Argenteuil have now been raised from the earth more than a month, and the leading bud of each shoot has recently been nipped out. The reason of raising the shoots so early from the earth in which they are buried, is that a longer stay would probably cause the fruit-buds to decay. The severe frosts that endanger the

Fig are over by the 20th of February. The trees are trained in huge bundles leaning slightly towards the earth, so as to facilitate their interment after the pruning in November. Some of the trees trained thus were very large specimens before the severe winter of 1870 and 1871. The people had to fly from their homes in the autumn of that eventful year, and as the trees were not buried, most of them were cut to the ground. Now, however, many of the young plantations are making rapid progress. It is not often one sees an example of culture in the open air so successfully adapted to adverse conditions.

LILY OF THE VALLEY FROM HOME-GROWN ROOTS.—Mr. Henry Wood, of Willow Lodge, Mitcham, has sent us some very remarkable spikes of Lily of the Valley, each bearing from fifteen to twenty flowers, each bell being nearly one-third of an inch in diameter. The roots which produced these fine spikes are of home growth.

A BEAUTIFUL SPRING-FLOWERING SHRUB.—We have lately (March 21) seen with Messrs. Thibault and Keteleer, at Sceaux, one of the most graceful and abundant-blooming, spring-flowering shrubs that could be desired. This was *Andromeda japonica*, a neat shrub, veiled over, and with pendent racemes of white waxy bells. The plant is unfortunately very scarce as yet; it is said to be hardier than the common and much smaller *A. floribunda*.

A SULPHUR-CROWNED CORBULARIA.—One of the most beautiful and distinct of all the hardy flowers which we have seen in bloom this week, is a large-flowered Hooped Peticotot Narcissus or Corbularia, sent us by Mr. P. Barr. The individual flowers are much larger than those of the common variety, but the main point of distinction, and one which contributes most to the attractiveness of the plant, is its distinct colour. The widely-expanded corona, which in all the other varieties known to us is of a deep rich golden-yellow tint, is in this case of a clear sulphur-yellow or primrose colour.—B.

THE FOUR SEASONS' STRAWBERRY FORCED.—This useful little Strawberry finds a place among the fruits and vegetables forced for the Paris market. It flowers and fruits freely and well in the little frames so much used round Paris plunged in stable manure. The Strawberries are planted out in autumn where they are to fruit, and when the lights are put over them, the plants are within a few inches of the glass. At present, being both in flower and fruit, they form a pleasing sight. In the market lately they have been worth twice the price of the larger kinds. In frames of the same kind the Parma Violets lately spoken of in THE GARDEN are grown.—V.

RHODODENDRON NUTALLI IN FLOWER.—An attractive flowering specimen of this greenhouse *Rhododendron* may now be seen in the conservatory at Claydene, Edenbridge, Kent. It is 9 ft. high, grows in a 14-in. pot, and is fourteen years old. It flowered for the first time in 1874, when it produced two buds and ten blossoms; in the following season it had three buds and nineteen flowers; and this year it has five buds and twenty-seven flowers—one truss consisting of eight flowers measuring 1½ in. in diameter; another truss has seven flowers, and two have six flowers. The average size of each bloom is 7 in. in diameter, and the depth of the cup 6 in. The blooms are pure white and very fragrant. The fifth bud will expand in a few days.—A. O. FELCOUR.

PLANTING ASPARAGUS AT ARGENTEUIL.—The present is the season of planting in this town, where Asparagus is cultivated so well. The planting season lasts from the first week in March to about the 20th of April. The best Asparagus in France is grown here, and by one system mainly. The plants, one-year seedlings (never more), are planted in shallow trenches 7 in. or 8 in. deep, the plants a little more than 1 yard apart, and the lines 4 ft. apart; no manure is given at planting, no trenching, or any preparation of the ground (beyond digging the shallow trench) takes place. In subsequent years a little manure is given over the roots in autumn, the soil thrown out of the trench, and forming a ridge between them, is planted with some crop in spring. In all subsequent years the soil is placed over the crowns in spring and removed in autumn. The culture is for the most part conducted by peasants who own their own ground; the size attained by the shoots is very remarkable. The soil varies a good deal, but not the system; good results are obtained in all soils by it. In planting on cold clay soils, the only difference made is that of planting a little shallower.

THE STEEL GLOVE FOR THE PHYLLOXERA.—This useful article, recently invented in France for the removal of the loose bark, &c., from the stems of Vines, is also used with good effect in removing Moss, &c., from other trees. A great deal of work may be done with it in a very short time, and the stems cleared of much that might afford cover to the eggs of insect enemies. It is very well made, and is lined with canvas to make it convenient to the hand.

PETUNIAS DOUBLE AND SINGLE.

PEOPLE are apt to look with disfavour on the *Petunia* as a bedding plant, but, nevertheless, it possesses great merits for decorative purposes, whether it be employed to form a mass of colour or a variety of tints. *Petunias* are not only free bloomers, but they last long in flower; and though a storm of rain may destroy the effect of a mass of them, two or three sunny days will soon brighten it up and restore to it its wonted beauty. Although I entertain a general dislike to the modern system of flower gardening, which consists in bold masses of isolated colours, I nevertheless admire the *Petunia* when employed in this way. There are a few varieties with self-coloured flowers, such as purple, rose, pink, &c., that, when propagated by means of cuttings, make a dwarf stocky growth, flower with remarkable freedom, and rarely produce seed. A bed of mixed colours is also highly attractive, and especially so when formed of the blotched and striped varieties. The first blooms of the finest strains of striped *Petunia* will, as a general rule, come self-coloured and then break into stripes and blotches of a very attractive character, which are more developed in hot weather than during rain. A pinch of seed of some good strain of striped *Petunia* will be certain to furnish some self-coloured flowers; and a few self-colours dotted about among the striped and splashed flowers afford a striking contrast; and then there is the additional advantage that the *Petunia* commences to flower when quite small in size, and continues flowering till cut down by frost. In some parts of the country *Petunias* are much grown as exhibition plants, and with remarkably good results. At Trowbridge, in Wiltshire, the annual exhibition being held in the end of August, *Petunias* in pots form a fine feature, but they are grown in a manner peculiar to the district. The plants are placed in large pots at least 8 in. or 9 in. in diameter, and the shoots are trained to a shield-shaped wire frame, which, leaning back, presents a front like that of an oval looking-glass. On plants thus managed I have counted as many as sixty to eighty blooms. I may add that it is only the free-blooming single varieties that are grown in this way. The double kinds are grown in the form of a bush, much as one would grow a specimen *Kalosanthes*. Both the single and double varieties make very good exhibition plants.

Petunias can be readily raised from seed, and any particular variety can be propagated by means of cuttings. Those who have a brisk bottom-heat at their command, may be content to sow their seed early in March, as it soon germinates; and by pushing their plants on they become strong by the end of May, when they may be planted out. Those who are not so well situated in the matter of heat, may sow their seeds in pans at the end of August, prick off the seedlings into shallow boxes, and winter them on a warm shelf of a greenhouse near the glass. It is by no means difficult to winter young plants of the *Petunia*. When planted out it should be into beds of rich soil, for when the plants get well established, a glorious head of bloom is invariably the result. In order to have a supply of cuttings of any particular variety, a few plants should be grown in 4½-in. pots during the summer, and wintered in them as store plants for supplying cuttings in spring; or cuttings may be taken of any particular variety in August, and put into 1½-in. pots, inserting from nine to twelve cuttings in a pot, and using a soil made up of two-thirds leaf-mould, one-third of mellow loam, and a little silver sand, taking care to have the pots well drained; these should have a gentle watering, be kept for a time in a close frame, and then wintered in the greenhouse. In spring these stock plants will supply many cuttings, which may be struck in a brisk heat in pans of sand. When rooted they should be potted singly in thumb-pots, and then grown on as required for planting out to flower in summer. It is not difficult to obtain a collection of fine varieties of both double and single *Petunias*. Of the former, King of Crismons, Mottled Beauty, Patroness, Favorita, Favour, Sensation, Mrs. Wilson, Diamond, and Minnie Evans, form a group of nine good and distinct varieties. They should be grown in pots and not planted out, giving them rich soil and good shifts, so as to keep them from becoming pot-bound too early in the season, plenty of air, and the branches should be kept well tied out. Of fine single varieties I may mention Spitfire, Moonstone, Black Knight, Master William, and Mrs. R. Roche among the self flowers; and among the striped and blotched varieties, Imperial, Mrs. William Elder, John Lindley, Mrs. Burron, Mrs. L. Wilson, and Miss Redman. But named varieties are now very plentiful, and any nurseryman can make up a small collection that could not fail to give satisfaction, while, from a good strain of seed, a large variety of striking forms would be forthcoming. D.

OPONTOGLOSSUM HALLI.—A plant of this *Opontoglossum* in Lord Lonsborough's garden at Norbiton, is now bearing numerous long, graceful flower-spikes, thickly studded with large and beautifully-marked blossoms. Associated with it are *O. crispum*, *O. Alexandra*, and *O. Pescatorei*, all in equally good condition.—C. S.

PALLAVICINI GARDENS, GENOA.

THERE is a curious garden at Genoa, that of the Villa Pallavicini, which well shows some diverse features of Italian gardening. It is on one of those steep hills which overlook the sea; it occupies a considerable space, for the most part covered with the native Evergreen Oak, through which many shady walks are made. These wind up the woody slope, and open here and there into little glades, embellished in various ways. For the greater part of its space, it is not laid out in what is called the Italian style; though there are the usual, and, on such slopes as this, the necessary terraces near the house. After these, however, the shady woods, with their native Oaks and Pines, and numerous wild Ferns and streamlets, and their many different peeps at the blue sea beneath, are refreshing. There is much to admire, were it not for the introduction of puerilities that might, perhaps, be in place in a tea-garden or in a rollicking playground, but not in a true garden.

—an ancient cemetery, in fact. Some antique sarcophagi, perhaps? or, it may be, the tombs of the owner's ancestors? Nothing of the kind—it is all artificial! Presently an Egyptian obelisk is seen, reminding one of some of those at Rome, but on getting nearer we find it is of terracotta! After this we ought to be grateful that the trees, too, are not artificial. Happily, a little way off, by the streamlet, there are masses of Maiden-hair Fern; there are plenty of Camellias, and other flowers (greenhouse ones with us) to soften matters a little. Passing by these, we soon arrive at a stalactite cave of distressing gloom and dimensions, after wandering through which a boatman is discovered, who ferries us through another tortuous winding or two of the cave, and soon ushers us into the fall sun in a small lake, with marble statuary and fountain, and round its margin a pretty flower-garden. Even this, however, like much of the place, suffers from being too much "cut up" and frittered away by small

View in the Pallavicini Gardens, near Genoa.

Sundry grottoes met with are arranged so as to syringe the visitor with water in various ways; and, as he escapes by the only open path, other cleverly-arranged jets attack him at every point. Imagine such puerilities in a garden rich with plants, and which, if it only possessed those native to the spot, would be lovely! There are half-a-dozen different contrivances, in different spots, for squirting water in this manner! However, here is an experimental plantation of Palms, and the larger kinds of succulent plants, that have been planted in the open ground for some years, and which compensates us for this infantile fooling. Here we notice that *Agave Salmiana* is much more massive and stately in port than the common American *Agave*, fine as that is in Italy, *Cocos campestris*, *Corypha australis*, *Cycas revoluta*, *Dasyllirion* in variety, and many species of *Agave*; presently masses of our greenhouse *Azaleas* are seen in bloom; and soon we come to a knoll of Pines and Oaks, where the golden light has some difficulty in penetrating; and here are sarcophagi, a warrior's tomb, &c.,

temples and tortuosities of various kinds. A Camphor tree in this garden is very fine, almost as handsome as a Plane in the spread of its branches. There is also a fine Cork tree, said to be the finest in Italy, but it is not half the size of the trees at Caserta, near Naples, nor quite so good as a tree at Linton Park, in Kent. There is a very remarkable specimen of *Cycas revoluta* planted out for some years, with a clear stem of 4 ft. which shows that this plant will flourish in a cooler temperature than is generally supposed. The garden, notwithstanding the objectionable features spoken of, is one of the best in Italy—its best aspects, however, rather arising from the beauty of the position and the natural woods which occur in it, than from the gardening. There is a noble greenhouse shrub cultivated here, and in many Italian gardens, called *Enkyanthus quinqueflorus*, reminding one of *Kalmia latifolia*. It is abundantly grown in tubs for placing in the open air in summer, and flowers very handsomely in spring. It well deserves extensive culture for conservatory decoration.

THE PLANT-LORE OF SHAKESPEARE.

Apricots.

- (1) *Titania*. Be kind and courteous to this gentleman . . .
 . . . Feed him with Apricocks and Dewberries.
Midsummer Night's Dream, act iii., sc. 1.
- (2) *Gardener*. Go, bind thou up those dangling Apricocks,
 Which, like unruly children, make their sire
 Stoop with oppression of their prodigal weight.
Richard II., act iii., sc. 4.

SHAKESPEARE'S spelling of the word Apricocks takes us at once to its derivation. It is derived undoubtedly from the Latin *præcox* or *præcocus*, under which name it is referred to by Pliny and Martial; but, before it became the English Apricot it was much changed by Italians, Spaniards, French, and Arabians. The history of the name is very curious and interesting, but too long to give fully here; a very good account of it may be found in Miller and in "Notes and Queries," vol. ii., p. 420 (1853). It will be sufficient to say here that it acquired its name of "the precocious tree," because it flowered and fruited earlier than the Peach, as explained in Lyte's "Herbal," 1578:—"There be two kinds of Peaches, whereof the one kinde is late ripe . . . the other kinds are soner ripe, wherefore they be called Abrecox or Aprecox." Of its introduction into England we have no very certain account. It was certainly grown in England before Gerarde's time, but the only account of its introduction is by Hakluyt, who states that it was brought from Italy by one Wolfe, gardener to King Henry the Eighth. If that be its true history, Shakespeare was in error in putting it into the garden of the queen of Richard the Second, nearly a hundred years before its introduction.

Ash.

- Aufidius*. O let me twine
 Mine arms about that body, where against
 Mygrained Ash a thousand times hath broke.
Coriolanus, act iv., sc. 5.

Warwickshire is more celebrated for its Oaks and Elms than for its Ash trees. Yet, considering how common a tree the Ash is, and in what high estimation it was held by our ancestors, it is strange that it is only mentioned in this one passage. Spenser spoke of it as "the Ash for nothing ill;" it was "the husbandman's tree," from which he got the wood for his agricultural implements; and there was connected with it a great amount of mystic folk-lore, which was carried to its extreme limit in the Yggdrasil, or legendary Ash of Scandinavia, which was almost looked upon as the parent of creation: a full account of this may be found in Malet's "Northern Antiquities" and other works on Scandinavia. It is an English native tree, and it adds much to the beauty of any English landscape in which it is allowed to grow. But to see it in its full beauty it must be seen in our northern counties, though the finest in England is said to be at Woburn.

The Oak, the Ash, and the Ivy tree
 O, they flourish best at home, in the north countrie.

Old Ballad.

In the dales of Yorkshire it is especially beautiful, and any one who sees the fine old trees in Wharfedale and Wensleydale will confess that, though it may not have the rich luxuriance of the Oaks and Elms of the southern and midland counties, yet it has a grace and beauty that are all its own, so that we scarcely wonder that Gilpin called it "the Venus of the woods."

Aspen.

- (1) *Marcus*. O, had the monster seen these lily hands
 Tremble like Aspen leaves upon the lute?
Titus Andronicus, act ii., sc. 5.
- (2) *Hocless*. Feel, master, how I shake. . . . Yea, in very truth do I,
 an 'twere an Aspen leaf.
2nd Henry IV., act ii., sc. 4.

The Aspen or Aspe (*Populus tremula*) is one of our three native Poplars, and has ever been the emblem of enforced restlessness. How this perpetual motion in the "light quivering Aspen" is produced has not been quite satisfactorily explained; and the mediæval legend that it supplied the wood of the Cross and has never since ceased to tremble, is still told as a sufficient reason both in Scotland and England. Its grey bark and

leaves and its pleasant rustling sound make the tree acceptable in our hedgerows, but otherwise it is not a tree of much use. In Spenser's time it was considered "good for staves;" and before his time the tree must have been more valued than it is now, for in the reign of Henry V. an Act of Parliament was passed (4 Hen. V., c. 3) to prevent the consumption of Aspe otherwise than for the making of arrows, with a penalty of an Hundred Shillings if used for making pattens or clogs. This Act remained in force till the reign of James I., when it was repealed. In our own time the wood is valued for internal panelling of rooms, and it is used in the manufacture of gunpowder. Gerarde's use of the tree must not be omitted, though it is probably the rudest remark that even he ever wrote:—"In English Aspe and Aspen tree, and may also be called Tremble, after the French name, considering it is the matter whereof women's tongues were made (as the poets and some others report), which seldom cease wagging."

Balm, Balsam, or Balsamum.

- (1) *K. Richard*.
 Not all the water in the rough, rude sea
 Can wash the Balm from an anointed king.
Richard II., act iii., sc. 2.
- (2) *K. Richard*. With mine own tears I wash away my Balm.
Richard II., act ii., sc. 1.
- (3) *K. Henry*. 'Tis not the Balm, the sceptre, and the ball.
Henry V., act iv., sc. 1.
- (4) *K. Henry*.
 Thy place is filled, thy sceptre wrung from thee,
 Thy Balm washed off, wherewith thou wast anointed.
3rd Henry VI., act iii., sc. 1.
- (5) *K. Henry*. My pity hath been Balm to heal their wounds.
3rd Henry VI., act iv., sc. 8.
- (6) *Lady Anne*.
 I pour the helpless Balm of my poor eyes.
Richard III., act i., sc. 2.
- (7) *Troilus*. But saying thus, instead of oil and Balm,
 Thou lay'st in every gash that love hath made me
 The knife that made it.
Troilus and Cressida, act i., sc. 1.
- (8) *1st Senator*. We sent to thee, to give thy rages Balm.
Timon of Athens, act v., sc. 5.
- (9) *Fearne*.
 Balm of your age,
 Most best, most dearest.
King Lear, act i., sc. 1.
- (10) *K. Henry*. Let all the drops should bedew my hearse
 Be drops of Balm to sanctify thy head.
2nd Henry IV., act iv., sc. 8.
- (11) *Dromio of Syracuse*. Onr fraughtage, Sir,
 I have conveyed abroad, and I have brought
 The oil, the Balsamum, and aqua vitæ.
Comedy of Errors, act iv., sc. 1.
- (12) *Alcibiades*. Is this the Balsam that the usurping senate
 Pours into captains' wounds?
Timon of Athens, act v., sc. 5.
- (13) *Quickly*. The several chairs of order, look you, scour
 With juice of Balm and every precious flower.
Merry Wives, act v., sc. v.
- (14) *Cleopatra*. As sweet as Balm, as soft as air, as gentle.
Antony and Cleopatra, act v., sc. 2.

In all these passages, except the two last, the reference is to the Balm or Balsam which was imported from the East, and was highly valued for its curative properties. It is now known that it was the produce of several Gum-bearing trees, especially the *Pistacia lentiscus* and the *Balsamodendron gileadense*; and now, as then, the name is not strictly confined to the produce of any one plant. But in Nos. 10 and 11 the reference is no doubt to the Sweet Balm of the English gardens (*Melissa officinalis*), a plant highly prized for its medicinal qualities (now known to be of little value) by our ancestors, and still valued for its pleasant scent and its high value as a bee plant, which is shown by its old Greek and Latin names, *Melissa*, *Melissophyllum*, and *Apiastrum*. The Bastard Balm (*Melittis Melissophyllum*) is a handsome native plant, found sparingly in Devonshire, Hampshire, and a few other places, and is well worth growing wherever it can be induced to grow; but it is a very capricious plant, and is apparently not fond of garden cultivation. "Très jolie plante, mais d'une culture difficile (Vilmorin). It probably would thrive best in the shade, as it is found in copses.

Barley.

- (1) *Iris.* Ceres, thou bounteous lady, thy rich leas
Of Wheat, Rye, Barley, Vetches, Oats, and Peas.
Tempest, act iv., sc. 1.
- (2) *Constable.* Can sodden water
A drench for surveined jades, their Barley broth
Decort their cold blood to such valiant heat?
Henry V., act iii., sc. 5.

These two passages require little note. The Barley (*Hordeum vulgare*) of Shakespeare's time and our own is the same. We may note, however, that the Barley broth (2) of which the French constable spoke so contemptuously as the food of English soldiers was probably beer, which long before the time of Henry V. was so celebrated, that it gave its name to the plant, Barley being simply the Beer-plant, and in Shakespeare's time, "though strangers never heard of such a word or such a thing, by reason it is not everywhere made," yet "our London Beere-Brewers would scorne to learne to make beere of either French or Dutch" (Gerarde).

Bay Trees.

- (1) *Captain.*
'Tis thought the King is dead. We will not stay.
The Bay trees in our country are all withered.
Richard II., act ii., sc. 4.
- (2) *Patrol.* Marry, come up, my dish of chastity with Rosemary and Bays.
Pericles, act iv., sc. 6.

It is not easy to determine what tree is meant in these two passages. In the first there is little doubt that Shakespeare copied from some Italian source the superstition that the Bay trees in a country withered and died when any great calamity was approaching. We have no proof that such an idea ever prevailed in England. In the second passage reference is made to the decking of the chief dish at high feasts with garlands of flowers and evergreens. But the Bay tree had been too recently introduced from the south of Europe in Shakespeare's time to be so used, though the tree was known long before, for it is mentioned in the Anglo-Saxon vocabularies by the name of Beay-beam, that is, the Garland tree; but whether the Beay-beam meant our Bay tree is very uncertain. We are not much helped in the inquiry by the notice of the "flourishing green Bay tree" in the Psalms, for it seems very certain that the Bay tree there mentioned is either the Oleander or the Cedar, certainly not the *Laurus nobilis*. But in the present day no garden of shrubs can be considered complete without the Bay tree, both the common one and especially the Californian Bay (*Oreodaphne californica*), which, with its bright green lanceolate foliage and powerful aromatic scent (to some too pungent), deserves a place everywhere, and it is not so liable to be cut by the spring winds as the European Bay. Parkinson's high praise of the Bay tree (forty years after Shakespeare's death) is too long for insertion, but two short sentences may be quoted:—"The Bay leaves are of as necessary use as any other in the garden or orchard, for they serve both for pleasure and profit, both for ornament and for use, both for honest civil uses and for physic, yea, both for the sick and for the sound, both for the living and for the dead . . . so that from the cradle to the grave we have still use of it, we have still need of it." The Bay tree gives us a curious instance of the capriciousness of plant names. Though a true Laurel it does not bear the name, which yet is given to two trees, the common (and Portugal) Laurel, and the Laurustinus, neither of which are Laurels, the one being a Cherry or Plum (*Prunus* or *Cerasus*), the other a Guelder Rose (*Viburnum*).

Beans.

- (1) *Poor.* When I a fat and Bean-fed horse beguile.
Midsommer Night's Dream, act ii., sc. 1.
- (2) *Carrier.* Pease and Beans are as dank here as a dog; and that is the next way to give poor jades the bots.
1st Henry IV., act ii., sc. 1.

The Bean (*Faba vulgaris*), though an Eastern plant, was very early introduced into England as an article of food both for men and horses. It is not apparently a romantic plant, and yet there is no plant round which so much curious folklore has gathered. This may be seen at full length in Phillips' "History of Cultivated Vegetables." It will be enough here to say that the Bean was considered as a sacred

plant both by the Greeks and Romans, while by the Egyptian priests it was considered too unclean to be even looked upon; that it was used both for its convenient shape and for its sacred associations in all elections; that this custom lasted in England and in most European countries to a very recent date in the election of the kings and queens at Twelfth Night and other feasts; and that it was of great repute in all popular divinations and love charms. I find in Miller another use of Beans, which we are thankful to note among the obsolete uses:—"They are bought up in great quantities at Bristol for Guinea ships, as food for the negroes on their passage from Africa to the West Indies." As an ornamental garden plant the Bean has never received the attention it seems to deserve. A plant of Broad Beans grown singly is quite a stately plant, and the rich scent is an additional attraction to many, though to many others it is too strong, and it has a bad character—"Sleep in a Bean-field all night if you want to have awful dreams or go crazy," is a Leicestershire proverb: and the Scarlet Runner is one of the most beautiful climbers we have. In England we seldom grow it for ornament, but in France I have seen it used with excellent effect to cover a trellis-screen, mixed with the large blue *Convolvulus major*.

Bilberry.

- Pistol.* Where fires thou find'st unaked and hearths unswept,
There pinch the maids as blue as Bilberry—
Our radiant Queen hates sluts and sluttery.
Merry Wives, act v., sc. 5.

The Bilberry is a common British shrub found on all Mossy heaths, and very pretty both in flower and in fruit. Its older English name was Heathberry, and its botanical name is *Vaccinium Myrtillus*, and we have in Britain four species of *Vaccinium*, the Whortleberry or Bilberry (*V. Myrtillus*), the Large Bilberry (*V. uliginosum*), the Crowberry (*V. Vitis Idea*), and the Cranberry (*V. Oxycoccus*). These British species, as well as the North American species (of which there are several) are all beautiful little shrubs in cultivation, but they are very difficult to grow; they require a heathy soil, moisture, and partial shade.

Birch.

- Duke.* Fond fathers,
Having bound up the threatening twigs of Birch,
Only to stick it in their children's sight
For terror, not to use, in time the rod
Becomes more mocked than feared.
Measure for Measure, act i., sc. 1.

Shakespeare only mentions this one unpleasant use of the Birch tree, the manufacture of Birch rods; and for such it seems to have been chiefly valued in his day. "I have not red of any vertue it hath in physick," says Turner; "howbeit, it serreth for many good uses, and for none better than for betynge of stnborn boys, that either lye or will not learn." Yet the Birch is not without interest. The word "Birch" is the same as "bark," meaning first the rind of a tree and then a barque or boat (from which we also get our word "barge"), and so the very name carries us to those early times when the Birch was considered one of the most useful of trees, as it still is in most northern countries, where it grows at a higher degree of latitude than any other tree. Its bark was especially useful, being useful for cordage, and matting, and roofing, while the tree itself formed the early British canoes, as it still forms the canoes of the North American Indians, for which it is well suited, from its lightness and ease in working. We still admire its graceful beauty, whether it grows in our woods or our gardens, and we welcome its pleasant odour on our Russia-leather-bound books; but we have ceased to make beer from its young shoots, and, on the whole, we hold it in almost as low repute (from the utilitarian point of view) as Turner and Shakespeare seem to have held it.

Blackberries.

- (1) *Falstaff.* If reasons were as plenty as Blackberries
I would give no man a reason on compulsion.
1st Henry IV., act ii., sc. 4.
- (2) *Falstaff.* Shall the blessed sun of Heaven prove a nicher and eat Blackberries?
1st Henry IV., act ii., sc. 4.

- (3) *Thersites*. That same dog-fox Ulysses is not proved worth a Blackberry.
Troilus and Cressida, act v., sc. 1.
- (4) *Rosalind*. There is a man hangs odes upon Hawthorns, and elegies on Brambles.
As You Like It, act iii., sc. 2.
- (5) The thorny Brambles and embracing bushes,
As fearful of him, part, through whom he rushes.
Venus and Adonis.

I here join together the tree and the fruit, the Bramble and the Blackberry (*Rubus fruticosus*). There is not much to be said for a plant that is the proverbial type of a barren country or untidy cultivation, yet the Bramble and the Blackberry have their charms, and we could ill afford to lose them from our hedgerows. The name Bramble originally meant anything thorny, and Chaucer applied it to the Dog Rose,

“He was chaste and no lechour,
And sweet as is the Bramble flower
That bereth the red hepe.”

But in Shakespeare's time it was evidently confined to the Blackberry-bearing Bramble. There is a quaint legend of the origin of the plant which is worth repeating. It is thus pleasantly told by Waterton:—“The cormorant was once a wool merchant. He entered into partnership with the Bramble and the bat, and they freighted a large ship with wool; she was wrecked, and the firm became bankrupt. Since that disaster the bat skulks about till midnight to avoid his creditors, the cormorant is for ever diving into the deep to discover its foundered vessel, while the Bramble seizes hold of every passing sheep to make up his loss by stealing the wool.”

As a garden plant, the common Bramble had better be kept out of the garden, but there are double pink and white-blossomed varieties, and others with variegated leaves, that are handsome plants on rough rockwork. The little *Rubus saxatilis* is a small British Bramble that is pretty on rockwork, and among the foreign Brambles there are some that should on no account be omitted where ornamental shrubs are grown. Such are the *R. leucodermis* from Nepal, with its bright silvery bark and amber-coloured fruit; *R. nootkanus*, with very handsome foliage and pure white rose-like flowers, *R. arcticus*, an excellent rockwork plant from N. Europe, with very pleasant fruit, but difficult to establish, *R. australis*, a most quaint plant, apparently without any leaves, and hardy in the south of England; and *R. deliciosus*, a very handsome plant from the Rocky Mountains. There are several others well worth growing, but I mention these few to show that the Bramble is not altogether such a villanous and useless weed as it is proverbially supposed to be.

Box.

- Maria*. Get ye all three into the Box tree.
Twelfth Night, act ii., sc. 5.

The Box tree is a native British tree, and in the sixteenth century was probably much more abundant as a wild tree than it is now. There were also probably more woods of Box in England than the two which still remain at Box Hill, in Surrey, and Boxwell, in Gloucestershire. From its wild quarters the Box tree was very early brought into gardens, and was especially valued, not only for its rich evergreen colour, but because, with the Yew, it could be cut and tortured into all the ungainly shapes which so delighted our ancestors in Shakespeare's time, though one of the most illustrious of them, Lord Bacon, entered his protest against such barbarisms:—“I, for my part, do not like images cut out in Juniper or other garden stuff; they be for children.”—(“Essay of Gardens.”)

Briar.

- (1) *Ariel*. So I charmed their ears,
That calf-like they my lowing followed through
Toothed Briars, sharp Furzes, pricking Gorse and Thorns.
Tempest, act iv., sc. 1.
- (2) *Fairy*. Over hill, over dale,
Through bush, through Briar.
Midsommer Night's Dream, act ii., sc. 1.
- (3) *Thi-be*. Of colour like the red Rose or triumphant Briar.
Ibid, act iii., sc. 1.

- (4) *Puck*. I'll lead you about a round,
Through bog, through bush, through Brake, through Briar.
Ibid, act iii., sc. 1.
- (5) *Puck*. For Briars and thorns at their apparel snatch.
Ibid, act iii., sc. 2.
- (6) *Helena*. Never so weary, never so in woe,
Bedabbled with the dew and torn with Briars.
Ibid, act iii., sc. 2.
- (7) *Oberon*. Every elf and fairy sprite
Hop as light as bud from Briar.
Ibid, act v., sc. 2.
- (8) *Adriana*. If aught possess me from thee, it is dross,
Usurping Ivy, Briar, or idle Moss.
Comedy of Errors, act ii., sc. 2.
- (9) *Plantageant*. From off this Briar pluck off a Rose with me.
1st Henry VI., act ii., sc. 4.
- (10) *Rosalind*. O! how full of Briars is this working-day world!
As You Like It, act i., sc. 3.
- (11) *Helena*. The time will bring on summer,
When Briars shall have leaves as well as thorns,
And be as sweet as sharp.
All's Well, act iv., sc. 4.
- (12) *Polygenes*. I'll have thy beauty scratched with Briars.
Winter's Tale, act iv., sc. 3.
- (13) *Timon*. The Oaks bear masts, the Briars scarlet hips.
Timon of Athens, act iv., sc. 3.
- (14) *Coriolanus*. Scratches with Briars,
Scars to move laughter only.
Coriolanus, act iii., sc. 3.
- (15) *Quintus*. What hole is this,
Whose mouth is covered with rude-growing Briars?
Titus Andronicus, act ii., sc. 4.

In Shakespeare's time the “Briar” was not restricted to the Sweet Briar, as it usually is now; but it meant any sort of wild Rose, and even it would seem from No. 9 that it was applied to the cultivated Rose, for there the scene is laid in the Temple Gardens. In some of the passages it probably does not allude to any Rose, but simply to any wild thorny plant. That this was its then common use, we know from many examples. One is enough from “A Pleasant New Court Song,” in the Roxburghe Ballads:—

I step me close aside,
Under a Hawthorn Bryer.

It bears the same meaning in our Bibles, where “Thorns,” “Brambles,” and “Briars,” stand for any thorny and useless plant, the soil of Palestine being especially productive of thorny plants of many kinds. H. N. E.

Strelitzia Reginae.—This is one of the most accommodating and continuous-blooming plants which we possess. We have two large plants of it, and just now one has seventeen and the other nineteen flower-spikes in full bloom, and they have been nearly equally well supplied all through the winter, and are likely to continue so for some months to come. Throughout the summer and autumn months they bloom more or less. We winter them in the coolest portion of the Palm-house, where the temperature at night is usually from 43° to 45°, but 37° or 40° is enough for them. During the summer months we put them out-of-doors on the terrace in the full blaze of the sun, and give them water when dry just as we do our Palms and other terrace pot plants. Some of our neighbours, however, keep their *Strelitzias* in summer in company with *Azaleas* and some other greenhouse plants out-of-doors, but in comparative shade, and I must admit that the leaves of their plants look better than the leaves on ours, but we still retain the credit for having the greatest quantity of flowers.—W. FALCONER, *Cambridge, Massachusetts*.

Toreñas.—*T. Fournieri*, *T. intermedia*, and *T. Thorelleana* are all the same. The plants are found in the gardens of the Pagodas in Cochinchina, where I have seen them.—J. G.

Black Auts and Peach Flowers.—Mr. Pearson (see p. 226) asks if any one has noticed ants attacking *Azalea* flowers. I have not observed them attack that particular flower, but I have on several occasions known them to injure the blossoms of Peach and Nectarine trees. As they are not easily dislodged, when once established amongst the roots of plants or trees, without injury to the latter, some means of trapping them generally have to be resorted to. This is however a slow operation, but if persisted in, their number may be greatly reduced, if not entirely destroyed.—J. G., *Henham*.

THE FRUIT GARDEN.

EXPERIMENTS IN VINE CULTURE.

SOME two years or so ago I promised to give some account of an experiment made with a house of Vines planted (if the term may be considered correct) without natural soil. It occurred to me that Grapes could be grown without soil, and I resolved to give such a method a trial in a small house 30 ft. by 12 ft. In August, 1873, immediately after gathering a crop of Black Hamburgs, the Vines, which for many years had been severely forced, were taken out. Immediately inside of the front wall I had the old soil removed down to the drainage for a width of 4 ft.; this was refilled with the freshest of last year's leaves and cow-manure pressed as firmly together as possible. The Vines were then planted, and a little soil was used to surround the balls; in November I added to the border 1 ft. outside and

thus prepared has produced fruit equal in every respect to what the house before produced, and to what houses of the same size are now producing where the borders have been prepared in the old way. The kinds planted were varied for the sake of experiment, and consisted of Dr. Hogg, Canon Hall Muscat, Barbarossa, Foster's Seedling, Black Hamburg, Duke of Buccleuch, Waltham Cross, and a seedling. There was nothing in the Vines or fruit that would lead one to suppose that they were growing in any other than an ordinary border. The Hamburgs were fine in colour and flavour, Canon Hall set like Hamburgs, and Waltham Cross had none of the small berries which it often produces from imperfect setting; this Grape was good, and well liked at the table in February at Lambton.

In the latter end of August, 1875, I planted another house of the same dimensions as the one just described, and with the view of retaining the turf as long as possible in a fresh

Another View in the Pallavicini Gardens (see p. 247).

4 ft. inside, made as before, when I found the roots in quite a promising condition. The material used was always in a fresh state, and this process was continued until last year, when the border was finished. I may add that top-dressing was oftener required than in the case of borders made with soil, as the border subsided more rapidly; the whole was covered with charcoal for the sake of appearance, no soil being used. After years of experience under the tuition of men famous in the Grape-growing world, I confess that the compost described appears to be a most unsatisfactory mixture in which to plant young Vines. The first part of the border made has become a light black soil without any adhesive texture, and is soft and spongy when trodden on. No doubt to some this experiment will appear very startling, more especially to those who condemn the practice of using manure in a raw state in the formation of a Vine border. But we are told that one fact is worth a thousand arguments. Now the fact is, this border

condition, it was not broken up, as is generally done when making a Vine border, but was put in the full size, 12 in. by 9 in.; commencing at the bottom and working upwards, I placed the turves as a mason would bricks in building, using cow-manure as mortar. As to the result of this arrangement, Mr. Westcott, of Raby, when looking over the gardens at Lambton, said, "Well, you have just gained a year on my young Vines," when only the year before I had congratulated him on their vigorous growth. I do not wish it to be understood that I prefer manure in which to grow Vines, or that I consider it better than other mixtures, but I believe it to be good along with them, and that no newly-made border is perfect without manure. Many ills are attributed to an over-rich border, such as mildew, gross growth, watery shoots, badly ripened wood, an abnormal amount of pith, shanking, badly coloured Grapes, and so forth; but when one ventures an experiment and finds that it puts all these aside, what then? There is much yet to be learned with reference to Vine culture, but when we are able to put our hands with more certainty

* Read at the Darlington Gardeners' Institute, March 15, by Mr. Hunter, Lambton Castle.

on the causes which produce the ills to which the Vine is heir, we shall become better able to remedy them. I am prepared myself (the more so after another year's experience) to say, that the growth of a Vine depends more upon the internal atmosphere, the amount of moisture it is charged with, and the light under which it is grown, than upon the richness of the border; it seems to me to be one of those plants which cannot be grown too fast or too strong. Some tell us that it is not from the strongest wood we get our finest fruit; that in some cases I grant, there being so many ways of growing and ripening the canes. A house may have every attention paid to it, it may be properly drained, looked through in the evening, and a temperature of 65°, 70°, or 75° rigidly maintained; yet if the Vines be encouraged to make their growth in darkness instead of daylight, the shoots will be watery, and there will be an abnormal amount of pith. From such management the stamina of the Vine is reduced until tendrils instead of bunches are the result. From the time when Vines commence to grow a little air should be considered of the greatest importance to them, and the quantity should be increased as the foliage becomes stouter and able to endure it. A given temperature sufficiently high for the well-being of the Vine can easily be maintained with a requisite quantity of air to prevent what we call watery shoots, if encouraged and grown in sufficient light by day. I hope some day to find instruments used as extensively to indicate the strength of light, as they now are to register the temperature correctly. Let me hope that these experiments may lead to some further researches in the same or some other direction that will be advantageous to Grape growers.

FIGS IN POTS.

I QUESTION whether there is any fruit tree grown that will maintain its fertility for such a lengthened period, or that will produce so much fruit from a given space, as the Fig. Restrict its roots either in pots or in brick pits, and its greatest amount of fertility will be ensured, for if allowed a free root-run in rich soil its energies are expended in producing gross, watery shoots and leaves, whereas, when starved into a fertile state, and furnished with short, hard, well-ripened shoots, fruit in abundance is the result. We have here at present, showing a capital crop of fruit, a quantity of Fig bushes that have probably occupied the same-sized pots for these last twenty years, and they are certainly more productive than young trees; in fact, I see no reason why a Fig tree might not do good service as a pot tree for a century. In selecting young Figs, the same rule should be followed as in the case of Gooseberry and Currant bushes, viz., those should be chosen which have single stems about 1 ft. high, and regular, well-balanced heads of branches should be formed by pinching out the points of the strong shoots as soon as they have attained the desired length; after the heads are well furnished with bearing wood, every shoot should be stopped at the third or fourth leaf, as the second crop under glass is usually more abundant than the first; and if well supplied with liquid manure, the trees will perfect both crops well, and likewise ripen off their young wood and an embryo crop for the first of the following year, but care should be taken not to excite growth before the trees have shed their foliage. As soon, however, as the fruit is ripe the trees should be kept as cool and airy as possible, and less root and atmospheric moisture supplied so as to ripen off the wood and induce a season of rest under as natural conditions as possible. I believe that the wood of pot Fig trees grown in this manner would stand without injury a degree of cold that would prove fatal to the soft, watery shoots that are frequently found on trees out-of-doors. Pot Fig trees are, however, always safest under some kind of protection, and as light is not absolutely necessary for them during the resting period, they may be set in any dark shed, and the Fig-house may be more advantageously employed up to the season when it is thought most desirable to re-introduce the Figs for the season's work, which must of course be regulated by the time at which the produce is most required. Figs will not only bear, but are greatly improved by a high temperature and plenty of moisture, the two chief elements in forcing, but along with them the plants should have all the light which it is possible to give them in our dull climate, for if grown under Vines or other kind of shade, only secondary results must be expected. As regards soil, I find nothing better than turfy loam and old mortar rubbish rammed hard into the pots, room being left for watering, which is one of the chief items in Fig culture, for when loaded with fruit and foliage, the amount of

moisture which a large Fig bush will require on a bright day is astonishing, and if allowed to get dry enough for the foliage to flag, the loss of the crop will probably be the result. J. G.

APPLE CROPS AND SPRING FROSTS.

THE failure of this, the most important of our fruit crops, last year was perhaps the most complete that has occurred during the last twenty years, for in former notoriously bad fruit seasons, in some favoured localities there were abundant crops; but the crop of 1876 was an utter failure all over the kingdom as regards large standard trees that supply our markets, and the main supply furnished by our gardens was derived from dwarf bush trees and espaliers. Here we had a good crop on espaliers in our walled kitchen garden, while on large orchard trees there was no fruit. It has become such an established custom to attribute fruit crop losses to spring frosts, that no other explanation of our failures in this respect is sought for, and the idea that the calamity is beyond our control prevents any efforts being made to check or alleviate it; yet minor details, if carefully worked out, might eventually considerably diminish, if not altogether overcome, the difficulty. There are a few points on which I cannot but think doubts ought to exist as to the losses of our Apple crops being wholly occasioned by spring frosts:—(1) How is it that Apples which flower considerably later than Pears, Plums, or Cherries, are oftener injured from some cause or other than either of the two kinds of fruits just named? (2) How is it that our surest-bearing Apples are nearly all early kinds, such as Keswick Codlin, Hawthornden, Cellini, and Lord Suffield, while some of the latest, as, for instance, Court Pendu Plat, that is not in flower until quite the end of May, is nevertheless not a certain cropper? (3) Why should dwarf trees and espaliers bear a crop when standards are almost, or quite bare, as the difference in temperature in which the two trees exist must be very slight; while, as regards protection, the lower branches of standards would be in a better position than either if the effects of spring frosts had only to be guarded against, as we often get a few Gooseberries destroyed on the topmost branches, while the fruit on the lower part of the tree is safe? My impression is that the blossoms of the Apple are seldom frozen sufficiently to destroy their vitality, but that cold winds and sudden changes of temperature occurring just at a critical stage of flowering, cause a certain amount of paralysis, so to speak, to be experienced by the whole tree, and as a result the blossoms drop, certain varieties being more affected than others. There can be no doubt that the Apple is the most important of all our fruit crops, and yet, as regards any certainty of supply, we are apparently more at the mercy of the elements than in the case of more tender fruits. The subject is well worth attention, and by a comparison of notes from sheltered and exposed situations, something like a certainty of supply might eventually be arrived at.

Henham.

J. Groom.

INSIDE v. OUTSIDE VINE BORDERS.

OF all that relates to Vine culture the making of the border forms the most important part. Errors concerning general treatment may be rectified; Vineries may be altered and modified with comparative ease, but if the conditions under which the root is placed be unfavourable, all the care and skill expended in other respects will be labour in vain. Grape-growing may be roughly divided into three heads, viz., early, mid-season, and late. Early Grapes, that is, those which ripen before the sun has power to raise the temperature of the soil, should have an inside border. Good early Grapes can be, and doubtless are, obtained from Vines which have their roots outside, but this can only be done at the expense of a considerable amount of extra labour, and merely serves to show what skill and care may achieve. As Mr. Grieve observes (p. 197), when two methods ensure the same success, it behoves us to choose that which is easiest to carry out. In the case of mid-season Grapes (those ripening during the summer months) little, if any, advantage would be gained by confining any portion of the roots to the interior of the house. During the swelling and ripening processes, which extend over the hottest and driest portion of the year, a thoroughly good root-run in congenial soil, combined with means of supplying abundance of water, is required, and that is best secured out-of-doors. With respect to late Grapes, that is, those that are not cut before January, the case is altogether different; they have to be kept some months after they are ripe. Having only the growth of the Vines in view, I should myself prefer outside borders for all Grapes which ripen during summer and early autumn, inasmuch as the roots are not only in a position to be benefited by the summer temperature, but they also get the benefit of whatever rainfall there may be. The question, how-

ever, is, whether Grapes can be easily, and with any degree of certainty, kept upon Vines, the roots of which are entirely outside, and whether greater success is not as a rule attainable where the borders are inside; and if so, whether the difference is great enough to overbalance other drawbacks, such as a more restricted root-run, extra labour in watering, &c. I merely put these questions. I do not attempt to answer them, not being in possession of sufficient data to be enabled to do so, but there are many probably who have had experience enough in this matter to warrant their expressing a decided opinion in reference to them. A comparison of notes and experience in regard to this subject would prove, I have no doubt, of great interest to many.

JOHN CORNHILL.

Byjlect.

THE CASHEW NUT.

I WAS much interested in the account which you gave of this Nut (see p. 211), having often eaten it roasted in the West Indian Islands; I have also purchased Cashew Nuts several times in the streets of London. The way in which these Kidney Bean-like Nuts are set on the end of the fleshy, Pear-shaped receptacle to which they are attached is always to me a matter of interest, and one which I have never been able to solve to my satisfaction, although we have an

Section of the Cashew Nut.

analogous arrangement in the Australian Cherries, the stones of which are nearly always on the outside of the pulp, which grows in a lump by the side of them. The common Strawberry, too, is another example of dry fruits being placed outside a fleshy receptacle, an arrangement the utility of which it is difficult to guess. J. E. S.

Early Melons.—Several growers have kindly favoured me with seeds of their early Melons, all of which I have sown and intend to test, and those that seem to indicate that they possess the qualities of fruiting in the shortest time from the sowing of the seed, and are fairly good in quality, shall be noticed in due time. With a careful and discriminating selection it would doubtless be possible to classify Melons into three sections, viz., early, midseason, and late, with as little trouble and as much certainty as is done in the case of Peas. This would be of great service to cultivators, for Melons are often in demand at certain seasons for shooting and other parties, and a mistake in the time of ripening the crop is often most vexatious, and is far worse than a similar mishap with Pine-apples or Grapes, for these will keep sound and good for a long time after they are ripe. Melons, too, will keep for a longer period without deterioration than is generally supposed, if cut just before they are ripe, wrapped round with several thicknesses of tissue-paper or thin sheets of cotton wool, and placed in a dry atmosphere at a temperature ranging from 50° to 55°; still of course they are a quickly perishable fruit, and ought to be used exactly at the right time, for if eaten too soon they are worthless, and if too late, they eat stale, and with an incipient flavour of decomposition that is altogether unpleasant. For both the earliest and latest varieties pot culture will be found the safest and fastest. The bottom-heat can be easily renewed around the pots, and thereby the roots can be kept at a uniform temperature, which is a great feature in the rapid growth and early maturity of Melons. Perhaps some of the numerous correspondents of THE GARDEN will favour its readers with the names of their early, midseason, and late Melons.—D. T. FISH.

American Apples.—About 250,000 barrels of Apples raised in America last year were shipped to Europe. More than half went to England, and 11,000 were taken to St. Petersburg.

BOG PLANTS AND UNDERGROUND TANKS.

I HAVE great pleasure in giving details of the underground tank (alluded to at page 121) for growing bog plants, but it must be remembered that my gardening experience is of a very youthful and experimental kind. Probably I shall not be able for several seasons to give perfectly satisfactory information about this mode of growing plants that require a large amount of moisture at their roots. Imagine a border about 50 yards long and 2½ yards wide, down the centre of which, about 1 in. under the surface, is laid a line of 4-in. clay pipes; each pipe is laid on a brick in a bed of mortar, and the joints are perhaps an eighth of an inch apart. The pipe does not appear aboveground, and the whole is on a slight slope. At the highest end of the border I have a large tank holding about 350 gallons of water; the border pipe runs into the tank, and has a valve which can be easily opened. A hand-spring well and pump fill the tank; the water is very hard when first pumped up, but after remaining a few hours in the sun it becomes soft and warm (on the hot days last July the water in the tank was at 77°), and I then pull up the valve. In about two minutes the whole of the 350 gallons have disappeared down the pipe, the water rushing along leaks out at each joint. I plant along the border and near the pipe such plants as want a moderate amount of water at their root, and if they need still more I put a few ashes close to the pipe joint, and plant their roots as close to the joint as I can. Many people come into this garden with nothing particular to do (a state of existence from which I have never suffered); I dare not set them to work with water-pots, as in giving relief to *Spiraea venusta*, they might step on *Dianthus Hentrianus*. Moreover, I find there are several herbaceous plants that will not stand being watered when the ground is hot and dry. Such well-meaning people are very well in their way, but I do not feel happy if they even press the ground with their feet; any one, however, can pump, and they may do so here to their heart's content. Indeed, I am thinking of being cicerone only to those who help to fill my tank. When the water is warm and well aired, I come fresh from my painting maybe, armed with a hook, and pull up the valve. Down goes the water with a rush, and in a few minutes I have done more for the plants and my own happiness than in an hour's work of the old fashion. Moreover, there is no stiff back, no wet clothes, no lost temper, no plant crushed. It is all very well for people who have lots of time and nothing to do in life to wheel about tubs and carry water-pots, but for a young painter just beginning to feel the value of every moment of daylight, a contrivance of this sort is very easing to the conscience. Whilst I am talking of this tank, I may as well give a few details about it, as I believe wooden tanks are not in common use, and it answers our purpose perfectly. It is all of 1½-in. deal, 22 in. deep, 3 ft. wide, and 11 ft. long. The sides are of two 11-in. planks, tongued and grooved, and sectionally bolted together. We opened the joints all over the tank with a blunt chisel, and caulked them with oakum, exactly like a boat's side; then the whole inside had a good coating of pitch with a little grease in it, and the outside was painted chocolate. It was some time before we got it quite water-tight, but it is all right now, and as long it is kept full I do not think it will leak. The valve at the bottom immediately over the border pipe is of sheet iron, with a rubber ring on the lower side, and this fits on to another rubber ring; the weight of the water not being sufficient to keep it quite water-tight, I put a weight on it and this answers the purpose. There is a strap of iron across the centre of the tank to prevent sagging. I have not yet come to the underground tank; it is really very difficult to describe, but if any readers of THE GARDEN happen to be in this neighbourhood during the summer I should be delighted to show them the results of my endeavours to grow plants that I cannot properly attend to when I am in my other home at Salisbury Street, Strand. The real and proper way to grow Lady's-slippers, Vernal Gentians, and other bog plants, would be to have them in immediate contact with running water, but I believe these plants may be grown in the hottest and driest garden, provided some provision is made for keeping the rainfall from passing away through the soil. I have several underground tanks considerably varying in size, but the description of one will suffice for all. During

the heat of last summer I took out the soil of my border 18 in. deep, about 10 ft. long by 4 ft. wide; the sides of the hole were dug slightly sloping. A compound of gravel and good lime well sieved and mixed together with water was laid about 4 in. thick all over the bottom and sides, and in a few days, when it was quite hard, we put over the surface of the concrete a slight coating of diamond cement. As soon as this was quite hard we had a tank capable of holding water, but instead of water we filled it up with peat and leaf-soil, putting some cinders for drainage at the bottom. When filled up level with the rest of the border there was no appearance of the underground tank, and the whole looks level and neat. Whatever falls in the shape of rain remains at the bottom till it has evaporated; no roots from surrounding trees or shrubs can penetrate the concrete. People come and see my Lady's-slippers growing vigorously, and think Nottinghamshire must be a very wet county, or that the soil is very suitable for Lady's-slippers. Close by one of these tanks, full of Trolliuses, Marsh Marigolds, and Lady's-slippers, I have a little cluster of Californian bulbs, which require exactly the opposite treatment, as these bulbs require to be kept as dry as possible. Without a tank I do not see how one could grow Lady's-slippers and Californian Tulips next to each other on the same border. I have not had full experience of herbaceous Phloxes under this wet treatment, but the finest Phloxes I ever saw were growing close to a railway cutting within 6 in. of stagnant water. In another large tank about 4½ ft. wide and 20 yards long, and into which my border pipe leaks freely, I have planted quantities of the very finest Phloxes and Irises; the tank is filled with leaf and turf soil, and I believe my Spiræas and Irises will flower grandly.

Bingham.

Plants in the Island of Capri.—A relative of mine has been residing, for the benefit of her daughter's health, during the past winter in the Island of Capri opposite Naples—and judging from the plants mentioned in her letters, that part of Europe seems to me to be a botanist's paradise—at least in winter and spring. The following are a few extracts from her letters. December 17:—My nosegay gathered in my last walk consisted of Maiden-hair Fern, Myrtle in full bloom, Jonquils, Narcissus, Arbutus with berries as large as our biggest Strawberries, and an evergreen creeper, (a leaf of which I enclose) which covers the rocks everywhere, at present covered with berries in most graceful bunches, like miniature purple Grapes; also a broader-leaved variety, which has pretty transparent red berries. [This is plainly *Smilax aspera*; I have had it in good health in my greenhouse for many years, but it has never flowered.—J. G.] The little silvery leaf enclosed belongs to a *Convolvulus*, and bears a beautiful flower in spring. That great Cactus with leaves like a battle-dore grows abundantly here. They call it the African Fig. They cut it down and dry it for fuel. The fruit is peeled before being sent to table, and the orange coloured juice is very cool and refreshing.—March 10—I have found three Orchises, the Spider, the Bee, and O. Morio. A *Cistus* is now in flower which is just like a Brier Rose bloom set on a Sage bush: there is both a pink and a white one. It is the *Cistus salviflora*; it would be a charming plant for a mixed border. One little wood is quite carpeted with a purple *Crocus*, viz., *C. Imperati*, and the spring *Cyclamens* and numerous varieties of *Violets* are now out. The little Fern which I enclose is coming up in patches on the walls. The crisp leaf of the barren frond looks a little like the Parsley Fern, and the fertile frond is much like that of the true Maiden-hair. I gathered some with a little round scattered sori upon the leaves.—In a letter dated December last, mention is made of meeting with immense patches of *Lithospermum* in full bloom, and many other interesting plants. In a letter dated March 4 it is said people who have lived here for ten years never saw such a severe winter. I yesterday saw ice 1 in. thick.—JACKSON GILLIBANKS, *Whitefield, Cumberland*.

Dandelions as Salad.—Dandelions are eagerly sought after at this season of the year by foreigners, especially French and Germans. On fine days I have observed them with a basket and knife searching Grass plots and banks for them, and carrying them home for salad. How is it that we English people do not do the same thing? Is it a question of taste, or is prejudice against anything common stronger in Britons than any other nation? "What's in a name?" it has been said; but under the name of "weeds" are frequently classed plants of more general utility than those we import at great expense and cultivate with assiduous care.—JAMES GROOM, *Henham*.

PLATE LXVII.

THE MOCCASSIN FLOWER.

(*CYPRIPEDIUM SPECTABILE* *).

Drawn by Mrs. DUFFIELD.

This plant is undoubtedly one of the most beautiful among hardy North American Lady's Slippers, and at the same time it is one of the most manageable from a cultivator's point of view; indeed, as regards beauty of form and delicate colouring, it is second to no other Orchid in the group to which it belongs, albeit that the genus itself is a large one, embracing some forty or fifty species, scattered in the nearly tropical, intertropical, and temperate climates of the world. *C. spectabile* was introduced to Kew about 1770 from North America, where it naturally luxuriates in woods, moist meadows, and also peaty bogs in the Northern States. Good native specimens produce from fifty to seventy flowers on a single tuft a yard across, formed on a thick, mat-like mass of fleshy roots, from which shoot up from twenty to thirty or more stout, erect, leafy stems nearly a yard in height. The plant is perfectly hardy in this country; plants, indeed, even which had been forced in pots have survived the winter although fully exposed, and have flowered the following season. It succeeds perfectly if planted out in a deep, rich, peaty soil, and if a few nodules of sandstone or rough sandstone grit be mixed with the soil, so much the better. We have also seen this Lady's Slipper thrive well in turfy loam on a moist, peaty bottom; in either case, however, deep planting is necessary, as the roots are then cool and moist during the hot summer weather, and they do not suffer from frost in the winter. In Messrs. Backhouse's nurseries at York, where this plant is well established, it forms stout tufts of stems, each of which is terminated by two or three great snow-white, rosy-lipped flowers about June or July. The plants here succeed in a deep bed of peaty compost, and have a western aspect, being so planted as to secure shade from the midday sun. This Orchid, having been quite recently largely imported, is consequently much more plentiful than formerly, but as it is one of those plants which none but a real lover of hardy flowers can grow in a thoroughly permanent and satisfactory manner, it is never likely to become a common plant. One interesting fact connected with this charming Orchid is that it may be forced as easily as a Tulip, by potting it in peat, and placing it in heat in January or February, removing it to the conservatory just as it comes into bloom; of course a succession may be kept up thereafter. Mr. Sturtevant (who has introduced quantities of this plant from America) and Mr. Bull have forced successfully plants of it started in heat in February and flowered early in April; and now that large quantities of its roots are easily imported, it will doubtless prove a valuable addition to our early, blooming indoor flowers. The forced plants, if allowed to die down gradually in frames or pits, may be planted out permanently in beds or borders in sheltered and partially shaded situations, where they will establish themselves and eventually flower well. The annexed illustration was prepared by Mrs. Duffield from a highly coloured variety, grown by Mr. G. F. Wilson, of Heatherbank, Weybridge Heath, who has been very successful in its culture, as well as in that of many other equally valuable hardy plants. A full descriptive account of all the *Cypripediums*—hardy as well as tender—will be found in *THE GARDEN* (1874), Vol. IV., pp. 43, 67.

B.

* *CYPRIPEDIUM SPECTABILE* (Swartz).—A hardy, herbaceous plant. Roots thick and fleshy, forming mat-like masses 1 ft. or more in diameter; stems erect, leafy, slightly fluted, and covered with soft white hairs attaining a height of from 1 ft. to 3 ft. Leaves (three to eight on a stem) 4 ft. 6 in. in length, 2 ft. 3 in. broad, sessile, broadly lanceolate in form, having numerous longitudinal nerves which give the foliage a plaited appearance; colour, bright green, sparsely covered with soft white hairs. Flowers terminal (two to three); sepals, oblong or ovate, 1 in. to 1½ in. in length, white, suffused with pale green at their apices; petals, linear, oblong or strap-shaped, pure white in colour, 1½ in. to 2 in. in length. Lip rounded, inflated, 1 in. or more broad; colour, creamy white, suffused in front with bright rose. Staminode, tongue-shaped, yellowish, spotted with crimson. Column, white. Anther cases yellow.—[Synonyms: *C. album*, Aiton; *C. Calceolus*, Linn. in part; *C. canadense*, Michaux; *C. hirsutum*, Miller; and *C. Roginae*, Walt. See also Linn. Trans. 1. p. 3. Bot. Reg., vol. xx., t. 1666. Sweet, Fl. Gard., 240. Wooster's Alpine Plants, vol. 1. pl. 6.]

MCCASKEY FLOWER. CYPRIPEDIUM SPECTABILE. E

GARDENERS' FRIENDS.

THESE are often in ignorance confounded with gardeners' foes, and treated accordingly. The one now about to be noticed is the nimble little lizard (*Zootoca vivipara*). This is generally regarded with aversion, not only by common people, but also by some who should know better, under the idea that it is venomous and next door to a snake. It is, however, a most harmless and timid little creature, graceful and elegant in its motions, and especially to be cherished by cultivators on account of the quantity of insects which it devours. These are its food, and the kind which it specially prefers are flies,

The Garden Lizard (*Zootoca vivipara*).

the different kinds of which do an infinity of damage in gardens, and are less easily caught in the perfect state than most other insects. It may be seen lying motionless basking in the sun until an insect comes within its reach, when it turns round with remarkable speed and snaps it up in a moment. It has sharp little teeth, which, however, are more useful for seizing its prey than rending it. It is common on most of our heaths and banks in England, but less so in Scotland, and it is also found in Ireland. It is said not to be common on the Continent. Unlike other lizards, this species is viviparous. A. M.

FRAME COVERINGS.

IN addition to what has already been stated in reference to these, will you allow me to contribute my idea about them for "South Italy's" information (see p. 14)? Let us take frames made of 1-in. thick and 2-in. broad deal board, and have them made immovable in themselves by nailing or inserting a board crosswise. After this, one side must be covered by some rough material nailed on the frame; the cheapest canvas, even worn Coffee bags, might do, nay, even Russia mats if not torn. This done, that material must be coated

inside and outside with thick oil paint; inside once will do; outside perhaps, according to the roughness of the material, three or four times will be necessary. The side exposed to the weather must be painted until the surface is entirely coated. Such frames are light, will last for years, and will be cheap. Of course every five years a fresh painting will be necessary, and if not in use they must be stored away in a dry place. Any handy labourer can make them, or an amateur may amuse himself with their manufacture.

Baden Baden.

MAX LEICHTLIN.

Trees on which Mistletoe Grows.—I have seen Mistletoe growing on a tree belonging to the Service family, called by the Italians *sorbo*, at La Cava, between Naples and Salerno, and I think I have also observed it on a Cherry tree in the vicinity of the town of Naples, and on Poplars between Rome and Naples.—CRAE.

— Mistletoe may be seen growing in the park here, and also in the open forest, on the White Thorns, that grow in hundreds; it may also be found on the Lime and Apple, but only once have I seen it on the Chestnut. Those on the Thorns are always the best, and produce the largest quantity of berries. Although old Oaks surround us, I have never seen Mistletoe on any of them. —A. HENDERSON, *Thoresby, Notts.*

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Indoor Plants.—Hard-wooded greenhouse plants of all descriptions, except Azaleas, which are better moved later on, should immediately be potted. It is a very great mistake to defer this operation (as is frequently recommended) until further on in the season, as then the greater amount of solar heat necessitates air being given to an extent that the plants cannot well bear for two or three weeks after potting, the ill effects of which are further aggravated by the then drier condition of the atmosphere. Another great advantage in early potting plants of this description is that whilst the weather is cool they do not require water being given so soon after; this also is a most important matter, as the more time that elapses before it is necessary to moisten the soil, the less chance is there of the roots suffering thereby, for despite the greatest care, there is always some mutilation in re-potting which renders them highly impatient of moisture. In all cases, see that the ball of every plant which has to be moved is thoroughly moistened beforehand; this should be attended to the day previous to potting, so as to give time for the water to drain off. Do not further disturb the roots than by the removal of the drainage crocks from the bottom of each ball; ram the new soil with the potting-stick until it is as close and solid as the ball of the plant, otherwise, when water is given afterwards, it will pass off through the new material, leaving the roots so dry that death or an unhealthy condition is sure to follow. In potting plants, amateurs very often fall into the error of placing them too high in the pots, the effects of which are more injurious upon hard than soft wooded subjects, the result to all being that there is a difficulty in watering, through insufficient space between the surface of the soil and the rim of the pot. All plants, large and small, should be placed sufficiently low in the pot for it to hold enough water at one application to moisten the soil, as where the watering of a plant has to be done by degrees in two or three applications (should this be omitted) the surface alone gets moistened. Some seed of *Celosia pyramidalis* should now be sown; it is well to sow it twice or thrice at intervals through the spring, by which means this useful decorative plant can be had in flower from the latter end of summer to the close of the year. Some Balsams, Cockscombs, (Globe Amaranthus, and Petunias, should also now be put in; sow in shallow pans sufficiently drained in fine sifted soil, made light and open by the addition of leaf-mould, also sifted, and a good sprinkling of sand; it is necessary thus to make the soil light in which to sow all such seeds as the above, for if this precaution be not taken when the seedlings are moved to separate pots, a considerable portion of their roots are sure to be broken, which seriously injures the plants. Fill the pans with soil, press down moderately firm with the bottom of an empty flower-pot so as to make it quite smooth, then sow the seeds and just cover with about an eighth of an inch of the finest of the soil. See that before using the soil it is neither too wet nor too dry—if the former, it will rot the seed; if the latter, it necessitates watering before germination takes place, which in the case of tender seeds should be avoided if possible. After they are covered thinly as above described, again press the surface in order to make it a little firm, which will have the effect of preventing the soil getting too dry before the plants are up. The pans should be placed in a stove, Vinery, heated pit, or hotbed, and the temperature at about 60°; if too cold, the seeds will perish. The sun should not shine directly on the top of the soil until the young plants have made their appearance, or it will dry the surface so as to require water being given sooner than it ought to be. Immediately these are through the soil, they must be placed where they will get plenty of light, and have air given, according to the state of the weather, in sufficient quantity to keep the plants stout and short, for if any plant of the above character that has to be grown in pots be ever allowed to become drawn, it renders them all but worthless. Helichrysums, French and African Marigolds, Phlox Drummondii, Portulacas, Tropæolums, and *Zionia elegans* (especially the double forms of this latter plant) are most beautiful, and deserving of a place in every garden. They should now be sown in pans or small boxes in soil similar to that recommended for the more tender annuals, but these, being more hardy, do not require so much warmth to induce them to vegetate; an ordinary greenhouse temperature will suit them. *Tropæolum canariense*, where required for running over low fences, walls, or ornamental archways, should be sown three or four seeds each in 4-in. pots, and, if they require it, give them a shift before the time for planting out, which will be towards the end of May. It is advisable to get the plants of this annual large and strong by sowing in this manner now, for although it will succeed well sown in the open ground later on, yet those sown in pots produce an effect much earlier in the season. Some more Stock and Aster seed should also now be put in, sowing some of the Stock seeds in small pots, as in

this way the plants, when newly vegetated, are less liable to damp than in pans; the Asters may be similarly sown in small pots, or in pans or boxes. Where Mignonette is required before it can be obtained from the open ground, ten or a dozen seeds may be sown in each 6-in. pot.

Herb Plantations.—Herbs in many gardens frequently do not receive the attention which they require; they are often found thrust in some out-of-the-way corner, where they become almost wholly neglected; from this cause their produce is but small, and their appearance very untidy; Mint especially, if it be allowed to occupy the same ground too long, exhausts the soil, which generally gets foul with weeds. Now is a good time to make a fresh plantation of Herbs; fork up the underground creeping roots, prepare a piece of ground in size proportionate to the supply required by digging and putting in a fair amount of manure, forming it into a bed about 1 ft. or 5 ft. wide; then take an inch or two of the soil off the top, lay on the roots not too thickly, and cover them with the soil that was removed, leaving the surface tolerably smooth. Growth will soon commence, but the produce will not be so soon ready as from an established bed, consequently it will be well to leave a portion of the old plantation undisturbed until that from the new is ready for use. Camomile, Pennyroyal, and similar Herbs, where required, should be planted in similar beds prepared in like manner, putting in rows 1 ft. apart small pieces divided from the old plants. Sage is best grown from cuttings struck in the latter part of summer, when they root freely; such as were struck at that time can now be planted in rows in a bed where they are to remain permanently, as also Borage and Fenel; the latter, from its taller growth, must have considerably more space allotted to it. The principal thing necessary with the above and any other Herbs that may be required is to keep the ground clear from weeds, and not to allow them to grow too long in one place. Chives.—Where these are held in estimation they may be fast increased by taking up and dividing the root clumps, replanting in thin rows. The planting of all the above should not be delayed, otherwise the season's growth is much interfered with through their not getting established in their new quarters before dry weather sets in.

Rhubarb.—This crop, from the great weight of its produce, quickly exhausts the soil; neither is it desirable to let it stand too long without removal, as plants that have been for some time undisturbed have a greater disposition to produce flowering shoots, which, even if cut out as soon as they make their appearance, interfere with the growth of the edible stalks; but it is not a good plan to disturb the whole plantation at once, as this stops the supply for a time. If some of the outside crowns be severed from strong established stools with a portion of root each, and planted now two or three together, and allowed to attain a maximum of strength, not gathering from them this summer, they will bear strong stalks next spring; or roots that have been forced through the winter planted now and permitted to regain strength through the summer, will succeed. As Rhubarb is a deep-rooting, gross-feeding plant, in all cases it should have rich deep soil, and if it be of a heavy, retentive nature some old exhausted tan, leaf-mould, wood ashes, or sandy road-drift, if such can be procured all mixed together, with 6 in. or 8 in. of good rotten manure, should be mixed with it, trenching the ground 2 ft. or 2½ ft. deep, planting 6 ft. apart each way. A crop of Radishes, Spinach, or Lettuce may be had off the ground betwixt the rows before the Rhubarb makes sufficient growth to interfere with them. Existing beds of Rhubarb will be much benefited by heavy drenchings with strong manure-water during the next two months.

Globe Artichokes should now have attention, removing the soil and stable litter or decayed leaves that were put round them in the autumn. Strong, established plantations produce a great deal more shoots than they can sustain, which, if allowed to remain, tend to weaken and interfere with the production of heads; four or five shoots are enough to remain on each plant, even when strong; remove all the weak suckers, retaining about the above number of the strongest; but in taking these off see that they come right out from the base, for if the leaves be merely pulled off, they will grow again directly. Where a supply of this vegetable is required as late in the season as it will grow, it is necessary about this time of each year to plant some suckers in numbers proportionate to the demand; some of the strongest of the above taken off with root fibres, planting three or four together in clumps about 1 ft. apart, are the best for this purpose, as if well attended to, they will bear good heads towards the end of August. Have the ground well prepared by digging and liberal manuring, and plant immediately, not allowing the suckers to flag; give water afterwards, and protect from the sun and drying winds with inverted flower-pots sufficiently large to cover without breaking the leaves; these may be used as occasion requires for ten days or a fortnight, until the plants get a good hold of the soil.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

April 2.—Potting Feverfew, Lobelias, and remainder of both kinds of Achyrantes; also Coleuses, and another batch of French Beans. Removing *Lælia autumnalis*. Sowing Stocks, Asters, Balsams, Cinerarias, Larkspurs, Picotees, Pansies, and Cockscombs; also Veitch's Perfection and Champion of England Peas, Long-pod Broad Beans, and a little Marjoram and Sweet Basil in heat; likewise Cabbage and Cauliflowers out-of-doors. Planting Cerastium; also Hollyhocks, and sheltering them with Laurel branches; likewise planting *Vinca minor*, autumn-sown Cabbage, Red Cabbage, and Cauliflower. Dividing *Dahlia*s. Grafting old Pear stumps. Disbudding trees and watering third Peach-house border. Earthing-up Cauliflowers under hand-glasses. Cutting Laurels. Hoeing among Roses and Strawberries. Cleaning Creepers in conservatory. Making a new Mushroom bed.

April 3.—Potting *Calceolarias*, *Delphinium formosum*, latest-struck *Heliotropes*, Mrs. Pollock *Pelargonium*, Crystal Palace *Tropæolum*, and *Verbena venosa*; also *Salvias*, *Centaureas*, and *Cineraria maritima*; likewise potting *Dendrobium Paxtoni* in small lumps of peat and broken crocks. Sowing Parsnips, Red and White Celery, and a frame of Radishes. Planting Arabis, Pinks, Carnations, Antirrhinums, and *Phloxes*; also Rhubarb and Potatoes. Pricking-off *Perilla* and Potatoes. Putting in a batch of Mint to force. Earthing-up Potatoes in pits. Emptying Vineries of bedding plants. Cleaning and dressing Globe Artichokes. Snaphoring *Vinca* pipes for red spider. Re-staking, cleaning, and tying *Lupagerias*. Hoeing among trees and shrubs. Cleaning and mowing all Grass.

April 4.—Potting *Dracenas*, Ferns, and first-sown Balsams. Sowing *Invincible* and other Sweet Peas, Mignonette, and Bush Basil; also Seakale in well-watered drills; likewise Summer Savory, Angelica, pot Marjoram, Salsafy, Spinach, and a second crop of Turnips. Planting *Salvia patens* and British Queen Strawberries. Top-dressing *Lilium lancifolium*. Earthing up Melons and watering Potatoes in frames. Preparing more land for Peas, and old Seakale land for Potatoes. Planting *Dielytras* for next year's forcing out-of-doors. Tying up late Vines. Putting *Artemisia* and *Nepeta* out-of-doors. Re-arranging conservatory. Watering Cauliflower plants under glass with guano-water. Staking Hyacinths in open flower-beds.

April 5.—Potting off Tomatoes and Capsicums, replacing them in heat, and shifting *Centaureas* and *Heliotropes* into larger pots. Re-potting large *Aerides*, and making up other small pots with the offsets; also *Cypripedium barbatum*, using nothing but Moss. Planting Globe Artichokes, Seakale, and Sir Harry Strawberry. Plunging *Rhododendrons*, Azaleas, and other forced shrubs in open ground. Preparing frame for Celery, filling up cracks in clay round grafts, and thinning fruit in third Peach-house. Hoeing and raking Strawberry plantations. Earthing up Cauliflower plants between rows of Peas; also autumn-sown Cabbage. Cutting July-sown Cabbage.

April 6.—Potting off *Taberoses*, *Thunbergias*, and Melon plants. Shifting Musk and Intermediate Stocks into larger pots; also young *Fuchsias*, Anne Boleyn Pinks, and *Kalmia latifolia*. Potting *Callanthes* in peat, loam, and leaf-soil in equal parts mixed with sand and crocks. Putting Moss over the drainage. Sowing *Zinnias*, *Gomphrenas*, *Godetias*, Globe *Amarantus*, *Primulas*, *Thunbergias*, *Mimulus*, and Borage. Planting selected Beetroot for seed; also Ash-top Potatoes and spring-sown Cauliflowers. Pricking off Annuals, White Celery, and *Perilla* in boxes and placing them in Vineries. Putting in *Bouvardia cutinosa*. Disbudding Black Hamburg and Muscat Vines, and thinning Grapes where ready. Earthing up spring-sown Cucumbers. Clipping Ivy. Clearing away Brussels Sprouts to make room for more Potatoes. Making up hotbed for Pink cuttings. Throwing out Celery trenches. Dividing *Mimulus*. Getting *Epacris* from conservatory and placing them in greenhouse. Putting *Camellias* in Peach-house and *Primulas* into cold frames. Commencing to water bedding plants in afternoon instead of morning.

April 7.—Potting *Achimenes*, Stocks, Sweet-scented *Verbenas*, and *Pelargoniums*; also *Chamaepeuce Casabone*, and putting them in Vinery. Shifting Castor-oil plants into larger pots, old *Fuchsias* into their flowering pots, and basketing large plants of *Vanda cœrulea*. Sowing Annuals in border, Mignonette among Rose bushes, and a bed of Sage. Pricking out Golden Feather *Pyrethrum*, more Lettuce, Cauliflower, first-sown Celery plants in frames. Thinning Carrots in frames, and fruit in Strawberry-house. Putting a few

Azaleas and other plants likely to be too forward into back shed to retard their flowering until wanted. Watering Potatoes, Carrots, and Lettuce. Tying up more Lettuce. Throwing up ridges for Vegetable Marrows. Trenching vacant land, and digging borders for Violets. Temperature—Late Vinery, ready for disbudding, 58° at night; second Peach-house, stoning, 55°; late Peach-house, ready for first thinning of fruit, 55° at night; Phaleuopsis-house, 75°; East Indian-house, 70°; Dendrobes, 65°; Odontoglossums, 55° to 57°; and Cattleyas, 65°; Strawberries setting, 55°.

THE INDOOR GARDEN.

CULTURE OF EUCHARIS AMAZONICA.

Of all the plants requiring stove treatment that have been introduced to Europe during the present century, there are few, if any, that have become more general favourites than this, or that better deserve to be grown by all who have the convenience of a house wherein can be kept up an amount of temperature sufficient to grow it. When the plant first made its appearance in the gardens of Britain, the extreme purity of its lovely white flowers, combined with their exquisite fragrance, at once produced an impression in its favour, even from the imperfectly grown examples that were first seen—imperfectly, so far that the small pot culture to which it was then thought best to confine it was not such as to admit of that full development which it has since exemplified under more liberal treatment, as the restriction of its roots to promote flowering (at first thought requisite) has been found altogether unnecessary, and so mischievous that it seriously interferes with the bulbs increasing in the same degree as when they are accommodated with plenty of space for growing. In this it differs from most bulbous plants, the generality of which do not succeed well under pot culture unless their roots are somewhat confined, whereas this *Eucharis* will thrive in any amount of room.

It has no particular season of flowering, as with suitable treatment the same plants will bloom three times in the course of the year, by subjecting them to alternate short seasons of growth and rest. To render it full justice, it should not be moved when in bloom to a conservatory or similar house that is cooler than where it has been brought on into flower, as growth should immediately follow the production of bloom, and it naturally receives a check if removed from heat. It is a remarkably effective plant in the stove, where its stout, ample, deep green leaves set off to the best advantage the numerous umbels of wax-like flowers that rise well above the foliage; but it is especially for the production of cut flowers for filling vases and for bouquets that it is most valuable, almost rivalling the *Camellia*. In addition to the individual flowers standing well when cut (which their peculiar texture and substance insure), it also has the merit of succession, each umbel opening consecutively, and also throwing up a succession of flower-stems, so that, when desired, almost every flower can be cut as required, a circumstance that has made the plant a general favourite with those who grow flowers for market, or who have to provide for private establishments where a continuous supply is needed. The plant is propagated by separating the bulbs, which increase moderately fast when well grown; but, like most other evergreen bulbous subjects, it does not like to have its roots much disturbed—which, whenever interfered with to the extent necessary in separating them, has the effect of retarding growth for a time; therefore the plants should only be broken up when they have either got larger than is requisite, or when it is desirable to increase the number. The time for carrying out the operation should also be chosen when growth is complete, not attempting it when the leaves are in course of formation, or when they are not fully matured. We will suppose that early in the spring a large plant exists which it is deemed advisable to break up, the growth of which is completed as above described; turn it out of the pot, and if the roots be very much matted and the soil of an adhesive nature, it will be very difficult to separate them without breaking; to avoid this place the plant in a tub large enough to admit the ball, and half fill it with tepid water, and work out all the soil with the fingers, which will leave the roots so that they can be separated with less breakage;

the bulbs may be divided with a knife at the point where they adhere to each other, or they can be parted by hand, placing them singly or two or three together in pots from 5 in. to 7 in. in diameter. The plant when growing requires a copious supply of water, consequently the pots must be well drained. They will thrive in good turfy loam, to which add as much sand as will keep it in a condition for the water to pass freely through it. Pot firm without injuring the roots, covering the bulbs to about half their depth. Do not give much water until growth has commenced; place them at once in a temperature of 70°; if they can be plunged in a bottom-heat 10° or 15° higher, they will progress all the quicker. In this temperature they will grow fast; shade slightly during the hottest part of the day in very bright weather, but in doing so do not darken the plants too much, or it will cause them to grow weakly; for this reason they should have as light a situation as can be given them. Let them have a moderate amount of air early in the day, shutting it off in good time, and syringing overhead at the same time. They will bear through the summer as much heat as the generality of stove plants. It will not be advisable the first summer to rest them for flowering, as it will be better to get as much growth as possible. About the beginning of August shift them into pots 2 in. larger; continue to keep them on with a liberal amount of heat and moisture, both at the roots and in the atmosphere, until the autumn, by which time they will have made considerable progress. At this time, when the leaves are fully matured cease shading, and gradually withhold water till the soil gets so dry as to cause the leaves to flag slightly, but not so as to injure them, giving a little before this occurs just to freshen them up, and again alternating the treatment by drying and then slightly watering them. Continue this treatment for seven or eight weeks, during which time they can be kept in a night temperature of 50° with a few degrees higher in the day, when they may be well watered and placed in 10° more heat; if they can be plunged in 10° higher than this, it will be still better. So managed they will quickly push up their flower-stems, and they should be encouraged by supplying them with plenty of water at the roots, and as much heat as is consistent with the diminished light of the season. Thus treated, after flowering they will grow on slowly through the winter, and after their full development they may be again submitted to the drying and resting process, after which increase the temperature, give water, and treat them in every way as before. This alternate growing, resting, and flowering, can be practised two or three times in the year with the best results without injuring the plants in the least; do not at any time pinch them for want of pot room. When the soil is well filled with roots they will be much benefited by a good soaking with manure water once or twice a week. For general purposes moderate-sized plants in 12-in. or 13-in. pots will be found the most convenient, but where it is desired, they may be grown on into specimens 6 ft. across, by simply using pots or tubs proportionate in size. When large they make fine exhibition plants, their general appearance being such as to contrast well with anything else.

INSECTS.—Most of the pests that infest stove plants will live upon *Eucharis*, but, from the nature of the leaves, they are much easier to destroy than on some subjects. If thrips or green fly make their appearance, fumigation will generally be found the best remedy, but from the regular use of the syringe, these and red spider are not often troublesome. Should scale or mealy bug gain a footing, they must be diligently sought for and removed by sponging, using a soft brush down to the base of the leaf-stalks where the bugs will lodge; and if these pests be not destroyed, they will soon increase to an extent that will both disfigure the plants and do them serious injury by the constant cleaning process requisite.

T. BAINES.

PROPAGATING VARIEGATED PELARGONIUMS.

SPRING-STUCK plants of these are for some purposes more useful than autumn-struck ones. The best way is to fill as many 3-in. pots as may be required, allowing half-a-dozen cuttings for each pot; use light, rich, sandy soil, and press it into the pots rather firmly; on the top of this place $\frac{1}{4}$ in. in depth of silver sand, and either water before inserting the cuttings or not, according to circumstances.

Plant the cuttings round the sides of the pots, and if they be large and have much foliage, perhaps less than six will be sufficient for each pot; at any rate, do not remove more of the leaves than will allow the cuttings to be made firm. When they are all in, water them with a rosed pot, and place them on shelves in the brightest and hottest part of any forcing-house available, where they can stand in the full sunshine. Our spring stock of cuttings is just rooted, and I am quite sure that we have not lost more than five per cent.; they have been placed on shelves at the back of a forcing-house, where the temperature never falls below 60°, and at closing time in the afternoon, it is often for a short time above 90°. Yet the cuttings have never been shaded, and they have scarcely lost a leaf; they have, however, always been kept regularly moist, and the watering was effected by introducing the pipe of a small watering-pot between the cuttings, and damping the sand carefully, yet thoroughly, without wetting their leaves. Damp being the great enemy to this class of plants when in a confined atmosphere, watering must be carefully done, and yet at the same time the soil must be kept in a moist condition if the cuttings are to root well and quickly. The cause of cuttings of tricolor and other variegated *Pelargoniums* damping off is not unfrequently due rather to the unequal condition the soil is in as regards moisture, than to too much water being given. Too often, from a fear of wetting them too much, they are allowed to get dust-dry, the tissues become shrunken, and yet, perhaps, the leaves do not flag. Well, after a time comes the watering-pot, and they get a good soaking as a matter of course; the tissues imbibe too much water—become gorged in, fact—and as a natural consequence the cuttings fog or damp off. When cuttings or seedlings damp off, the cause might often be found in a previous period of neglect, rather than a present superabundance of moisture.

E. HOBDAY.

EUPHORBIA JACQUINIEFLORA.

VIEWED either as regards its general usefulness or for the exquisite beauty of its bright cerise-coloured flowers, the *Euphorbia jacquiniæflora* stands quite unrivalled as a winter-blooming plant, and is one of those good things of which it may truly be said that one can cut and come again, as the cutting is but the prelude to a fresh crop of flowers being produced, for the top is no sooner removed than the plants break again, and, from having more branches, are even more attractive than before. The loss of so much growth as is necessarily entailed where cut blooms are in great request, is a serious matter for most plants, but in the case of the *Euphorbia jacquiniæflora* no damage is done by the cutting, and its value is not deteriorated in any way beyond the loss of its flowers, the removal of which only forms part of the requisite pruning to which the plants have to be subjected later on in order to get young wood for propagating or to grow on for another season's display. Although the individual blooms are small, they are produced in such profusion and are so elegantly arranged as to form the most charming natural wreaths for ladies' hair, for which purpose they are peculiarly adapted, and are always special favourites. Besides being of such great value for cutting, they are equally serviceable as pot plants for decorative purposes in either large or small sizes, the latter of which are specially suited for the embellishment of dinner-tables, where their gracefully arching branches and the rich glow of colour of the flowers with which they are so thickly studded show off to great advantage in contrast with the usual surroundings.

The *Euphorbia jacquiniæflora* is naturally of a loose, straggling habit, but nevertheless it is a very tractable plant to manage, and readily conforms to any mode of training or to any style of growth, from the weak bush form of from 1 ft. to 2 ft. high, up to large specimens, or even to cover the back wall or roof of the stove, which is perhaps the best way of all to cultivate it where quantities of cut flowers are required. Planted out in a well-drained border, and grown in this way, with sufficient room for its branches to spread and develop themselves, there is scarcely any limit to its capacity for blooming, especially if it be so situated as to have plenty of light and sunshine to consolidate and ripen the wood, which is a very important matter with all sappy plants of this class. An intermediate-house suits it even better than a stove, as a temperature varying between 55° and 65° is amply sufficient for it during the whole of the winter, provided the atmosphere is correspondingly dry; and flowers that expand under

such conditions always possess more substance and last considerably longer than those that are subjected to more heat.

Treatment when Planting out.

If planted out in either of the above structures, it is of the greatest importance that the border should be well drained, for although fond of water when growing freely, anything approaching a wet and sour state of the soil is fatal to success. In a border of 2 ft. deep, at least 6 in. ought to be given up to drainage, and this should consist of broken bricks or some warm, dry absorbent material of that kind, over which it will be necessary to place some rough, freshly-cut turves, in order to prevent the soil from working in amongst it, thus filling up the interstices and defeating the object in view. The remaining space should then be filled up with a mixture of peat and loam or leaf-soil, and the latter in about equal proportions, with a liberal admixture of sharp clean sand to keep the whole open and porous. A plant turned out at once under such favourable conditions will not be slow in establishing itself if properly cared for during the summer; and where space can be afforded, I know of nothing more deserving or serviceable, or that will make a better return, than this beautiful *Euphorbia*, affording, as it does, plenty of cut flowers for at least two months during the dullest time of the year, when flowers of a bright colour are sadly deficient, and consequently doubly appreciated. The best way of treating this plant when it is planted out, is to allow it to fill the allotted space as quickly as possible, and then to nip out the ends of the shoots to induce them to break again, which will greatly multiply the number of sprays for cutting, and they will be of a more convenient size than those on the main branches; but the stopping should not be deferred later than the end of July or middle of August, otherwise there will not be sufficient time to ripen the lateral growth formed afterwards. To aid in this matter, the plants should be kept somewhat drier at the roots in the autumn with a corresponding diminution of atmospheric moisture, which will soon harden the wood and induce them to form plenty of flower-buds that will readily expand when water is again applied after the turn of the year. The habit of *Euphorbia jacquiniæflora* renders it very suitable for training loosely to trellises, and where convenience does not exist for planting it out, fine specimens may be grown in this way from which immense quantities of bloom may be cut, or that will be aglow with colour, and objects of great beauty for decorative purposes where large plants are required. Neat light wire frames made pyramid-shape are the best for the purpose of training them on, as being less conspicuous than stakes, they are not so obtrusive and accord better in size with the branches; but when treated in this manner, the tying should be done in such a way as to leave the branches tolerably free that the plants may be natural-looking instead of having that stiff, formal appearance so objectionable to a well-trained eye. Excepting for warm conservatories or greenhouses, the *Euphorbia jacquiniæflora* is not available; and even in these, to be safe, it must undergo a preparatory process by a gradual inuring to the change. Plants required for this kind of work should never be grown in bottom-heat nor in a temperature higher than is absolutely necessary, that the change they undergo on removal may be as slight as possible. When subjected to bottom-heat, there are few things that will endure a house many degrees lower than the one they have been grown in, and *Euphorbias* are as sensitive to this as most plants, and equally quick in showing how much they resent it. In a low temperature such as that of the conservatory or greenhouse, care should be taken to set them in the warmest position away from the influence of draughts, or where air is admitted, and never to give more water at the roots than is absolutely necessary to keep them from flagging.

In Pits or Frames.

During summer, when shelves in the stove become too hot and dry for their well-being, they may with advantage be transferred to any pit or frame, where they will be more under command, and can be syringed and treated as occasion requires. Unless during the very hottest part of the day shading will be unnecessary, and if closed early and damped overhead, there will be no difficulty in maintaining them in robust health with

the leaves in that fresh, glossy condition that adds so much to their beauty. In whatever situation they are grown they should always be kept well up to the glass, that they may be as short-jointed as possible, and make a firm, woody growth. When simply required for cutting from, and good sprays are the object aimed at, the plants should be allowed to have pretty much their own way during the summer, and when winter sets in they should be ranged along the front wall of the stove close up to the glass, under which the tops can be loosely tied to string strained from rafter to rafter, in which position the flowers not only come stouter in texture, but likewise much brighter in colour.

In Windows.

As a window plant in a warm room *E. jacquiniæflora* is perfection, and although it will not stand for any great length of time in such a position, it may be propagated so readily, and got up to flowering size with so little trouble, that it is worth growing extensively for this purpose alone. For all uses of this kind and for table decoration, small, neat plants, in 4-in. or 6-in. pots, are the most serviceable. To have them in this form, they should be propagated during April or May, and when rooted potted in sandy peat and loam, and then placed for a few days where they can be kept close and moist till they get hold of the soil, after which a light, airy situation, such as that of a shelf near the glass, must be accorded them to keep them from drawing. In order to have them dwarf and bushy, frequent stopping of the leading shoots will be necessary, which will induce them to break back, so that by the end of the season a number of short, twiggy branches will be formed, all of which will flower in the most profuse manner if properly ripened.

Propagation by Cuttings.

When plants of these have done blooming, they should be kept dry at the roots for a time preparatory to cutting them back, to obtain cuttings for propagating, or to induce them to break for the purpose of growing them on again to get extra-sized specimens. If an increase of stock be the object, the cuttings should be taken off when about 4 in. long, with a piece of the old wood at the base to form a "heel," without which it is a difficult matter to strike them with any degree of certainty, as they invariably turn black and fog off. To get the cuttings firm and short-jointed, the plants, when started by keeping them just moist at the roots and well syringed, should be placed well up to the light in an airy situation, the cuttings from which will be found to root readily, if inserted in sandy soil in well-drained pots, and then placed in a propagating-box, where they can receive a brisk, moist heat, or under a bell-glass in the stove, where they can enjoy the same favourable conditions. Many cultivators, both professional and amateur, have been known to fail in the propagation of this very desirable plant, from endeavouring to do so from the old wood, or in taking the cuttings from the plants without beels and when they are long and soft from want of exposure; but if only such cuttings as those that are noticed above be taken, nearly all may be expected to grow.

Insects.

The only insects that affect *Euphorbias* in a sufficient degree to cause injury or check their growth, are green fly and scale the former of which is easily got rid of by fumigating with Tobacco, but the latter is a more troublesome pest to deal with, and can only be removed by hand-washing. Fortunately, they first effect a lodgment on the stems, from which they can be readily ejected by means of a soft sponge or brush, and this should always be done before they get on to the leaves or amongst the foot-stalks of the blossoms, where they cause much disfigurement, and whence it is a most difficult and tedious matter to dislodge them. Insecticides are but of little use for the purpose of cleaning such plants as these from an insect that is so easily destroyed as soft brown scale, and as there is some risk to the tender bark of the plant in applying these mixtures, they had better be avoided.—S. J.

Long-tailed Croton (*C. M'Arthurianum*).

***Livistona chinensis*.**—Of this fine Palm we have here perhaps the finest specimen in the United States. It is in vigorous health, and is planted out under glass, and this winter has produced four immense branching flower-spikes that measure from 3 ft. to 4 ft. long, and that are now thickly set with fruits which I trust will ripen. It is 18 ft. 6 in. high, and 22 ft. by 19 ft. through in spread of leaves; it has a trunk 14 ft. 6 in. in height, 5 ft. of which at the base are naked, that is, without leaves. The butt or swollen part of the stem next the ground is 5 ft. in circumference, and the trunk, $1\frac{1}{2}$ ft. from the ground, is $2\frac{1}{2}$ ft. round. It has forty-nine fully developed and healthy leaves, the "fans" of which, including the pendent segments, are from 5 ft. to 6 ft. 3 in. across. Last autumn this plant was so vigorous that it sent its young leaves 2 ft. through the roof of the house; but on the approach of winter these leaves were cut away, and several since, in all eleven, because it is impossible to bend them, so near the glass is the crown of the Palm. We cannot save this magnificent specimen another year, as the house will not contain it, and it is in too dilapidated a state to be enlarged. The leaves of the *Livistonas* are well known to be terminal and fan-shaped, divided into numerous segments, which are split at the apex, and frequently have threads hanging between them, while the foot-stalks are sheathed at the base

in a mass of netted fibres, and are often prickly along the edges. Their branching flower-spikes grow out from amongst the leaves, and have several incomplete leathery spathes surrounding their stalks. The flowers have a three-lobed calyx, and a three-parted corolla, and the fruits are dry and one-seeded.—W. M. FALCONER, *Botanic Garden, Cambridge, Massachusetts*.

LONG-TAILED CROTON.

(*C. M'ARTHURIANUM*).

A WELL-GROWN specimen of this handsome new Croton was exhibited for the first time at the last meeting of the Royal Horticultural Society at South Kensington, and received a first-class certificate as an attractive decorative plant. It is robust yet compact in habit, the irregularly-undulated, strap-shaped leaves being nearly 2 ft. in length, and $1\frac{1}{2}$ in. to nearly 2 in. in breadth, their apices curiously lengthened out into tail-like points. Their colour is a glossy green, conspicuously veined, marbled, or blotched with golden-yellow, the petioles and midrib being tinged with orange or soft red. The plant

grows freely under ordinary stove culture, and well deserves attention as a distinct variety of a popular group of fine-foliaged plants.
B.

THE LIBRARY.

AGROSTOGRAPHIA; OR, A TREATISE ON CULTIVATED GRASSES.*

WHEN a book has reached a sixth edition, as this has done, critical remarks respecting it are scarcely called for; nevertheless we are glad to direct attention to it, inasmuch as it contains much useful information, historical as well as cultural, and is moreover copiously illustrated with figures of all the Grasses cultivated for forage or pasture, as well as those best suited for lawns and pleasure grounds; of the latter the following Table affords an example:—

FOR FINE LAWNS, CROQUET GREENS, BOWLING GREENS, BLEACHING GREENS, &c.

Kept constantly under the scythe.

NAMES OF GRASSES.	Light Soils.		Medium Soils.		Heavy Soils.	
	With a Crop.	Without a Crop.	With a Crop.	Without a Crop.	With a Crop.	Without a Crop.
<i>Avena flavescens</i> ...	1	1	1	1	—	—
<i>Cynosurus cristatus</i> ...	8	8	9	9	10	10
<i>Festuca duriuscula</i> ...	3	3	4	4	5	5
<i>ovina tenuifolia</i> ...	2	2	2	2	1	1
<i>Lolium perenne tenue</i> ...	15	20	20	22	22	24
<i>Poa nemoralis</i> ...	2	2	2	2	2	2
<i>peruvianus</i> ...	2	2	2	2	2	2
<i>trivialis</i> ...	1	1	1	1	1½	1½
<i>Trifolium repens</i> ...	6	7	6	7	6	7
<i>minus</i> ...	2	2	2	2	1	1
	15	18	49	52	50½	53½

Tables are also given showing the kinds and quantities of Grass seeds required for sowing an imperial acre for permanent pastures of various kinds. In other Tables the best mixtures of Grasses for laying down irrigated meadows, or for sowing in woods, or beside shady woodland walks, are pointed out as well as those Grasses best suited for growing on heaths and moorland, or on rocky and gravelly soils of the most barren kind. Apart from descriptions of all native and foreign Grasses used in this country for pasturage, a copious list of both their English and scientific names is given. This edition, the work of Mr. Syme, the manager of the Lawson Seed and Nursery Company, well deserves a place in every garden library, containing as it does information and statistics not to be obtained elsewhere.

ORCHID CULTURE.†

THIS is an interesting and well-printed work, consisting of upwards of 400 pages, and containing much information on the culture of a now popular group of exotic plants. The book is written for American cultivators who have to contend against a more variable climate than even that of England, their summers being hotter and drier, and their winters much colder; nevertheless there are many cultural hints in this volume which an intelligent cultivator may turn to account. The main value of the work, however, will be for occasional reference as to nomenclature or as an index to books containing coloured figures of the different plants of which there is a list given under each species. Lists are also given of the best kinds for large and small collections; and a glossary at the end explains the technical terms used, and also affords much valuable information relating to the termination of specific names. There is also a tolerably complete list of collectors and amateurs, &c., to whom either genera or species have been dedicated. In short, this is undoubtedly the most comprehensive of all popular hand-books on Orchids and their culture, and it is one which no English cultivator who wishes to be fully posted up in all matters relating to them can afford to be without.

THE FLOWER GARDEN.

LILY BULBS.

IN "F. W. B.'s" remarks (see p. 188), he says:—"Dunedin" has not assisted us so much on this subject as at first sight he appears to have done." I am sorry, indeed, that on second sight he should have been disappointed. He says, in opposition to my doctrine:—"The surrounding scales do not necessarily perish, since in many Lilies, and especially in *L. davuricum*, they become detached from the bases of the old flower-stems, and form a whole colony of young bulbs." So much the worse for the new bulb, I say. But what has this to do with the continued succession of any particular bulb? If any of the surrounding scales drop off, it must be caused by rough treatment or carelessness; for Nature does nothing by halves, nor is any bulb clothed with superfluous coverings. There is not, in fact, a single scale which is assigned to a Lily bulb that is not absolutely necessary for the nourishment of the new bulb within it; and it was on this account that I said:—"When lifting and transplanting bulbs the greatest care should be taken not to damage the scales." "F. W. B." says, moreover;—"The term 'seed bud' used by 'Dunedin' is an old one, and is calculated to mislead, inasmuch as the mode of reproduction which he mentions has nothing to do with the seed whatever, and is simply an axillary or scale-bud, popularly known by cultivators as an 'offset.'" I admit that the term "seed-bud" is an old one, but I do not admit that it is calculated to mislead. Those who will take the trouble to look carefully into this matter, will ere long find that the seed-bud, and the seed-bud alone, has everything to do with the reproduction of the new bulb and the continued succession of its race. As an incontrovertible proof that I am misleading no one, I send you a portion of a bulb which I lifted and dissected in January last. On the right, as it is fixed on a card, you will see the remains of the inner scale; on the left is a portion of the new flower-stem; and between the two you will see the seed-bud distinctly about the size of a canary seed. In order, however, to leave no room for doubt I send you portions of three bulbs of the same kind which I lifted only three days ago. I have picked off the scales carefully until I arrived at the base of the flower-stem, where I knew I would find what was once the germ or seed-bud, but which has now grown so much since January last as to entitle it to be called a young bulb. You will see in all the three specimens that the young bulbs are growing as close to the flower-stems of the parent bulb as the seed-bud is growing in the younger specimen. About ½ in. from the base of the new flower-stem you will observe a round scar which marks the seat of the old flower-stem before it had entirely died down. Opposite to this scar on the other side of the new flower-stem—and this is worthy of special observation—you will see, in all the three cases, that it is there where the young bulb is seated, thus showing that the true or legitimate seed-bud has a pre-determined or settled position in the parent bulb, namely, on the opposite side of the old flower-stem, the new flower-stem being always between them. The seed-bud and the three young bulbs which I submit for your inspection, are the true and legitimate reproducers of the bulbs of their race. Experience teaches us where to search for and where to find them, but no amount of experience can teach us where we are sure to find axillary, adventitious, accidental, or any of the other buds mentioned by your correspondent, before they actually present themselves to our view. All small external buds (called adventitious), wherever they may present themselves, should be removed as soon as possible and treated as offsets, otherwise they will rob the principal bulb of its due share of nourishment, and thus prevent us from growing large plump and perfect bulbs. The true or legitimate seed-bud of the year would then grow and flower strongly the following season, more so, possibly, than even its predecessor had done before; while, on the other hand, not one of all the various buds that are named and set forth to oppose my doctrine, will do anything of the kind.

I send you the half of a bulb of *Lilium*, which I lifted and cut in two vertically, last October. As it has been exposed to the air ever since, it is of course shrunk and shrivelled up to half its original size. Within it, there are two well-grown

new bulbs, which, you will observe, have sprung from the same source, as if the germ, when it vegetated, had generated two seed-buds instead of one, which consequently have grown up to what are properly called twin-bulbs—not offsets. This will account for the fact that we sometimes see two stems growing or shooting up apparently from one bulb, and both flowering well the same year; sometimes, but rarely, a Lily bulb has three at a birth. "F. W. B." observes that "there are one or two points about Lily bulbs on which I am by no means clear, and I trust that 'Dunedin' may be able to render us some assistance. For example, I had always been led to believe that growth might take place without leaves, but that this was at the expense of substance, or cells previously stored up in the plant; we have, however, what appears to be trustworthy proof that Lilies not only become larger in the bulb, but also more weighty without the assistance of leaves." This is a question which is very easily answered. As a general rule, the month of October is considered to be the best time for lifting and transplanting bulbs, as at that time the plant is to all appearance in a dormant state, all outside the bulb being in a natural state of decay. But inside the bulb this is not so. The new bulb is growing with continued freshness, feeding on the stores laid up in the scales of the parent bulb. The result of this is that frequently the new bulb grows to a much greater size than its parent, especially if the parent bulb happen to have been planted in congenial soil, from which it has drawn into its scales a full supply of nourishing sap. It is, of course, as "F. W. B." supposes, at the expense of the substance stored up in the scales of the old plant; for the old plant is Nature's store-house for this very purpose, and as soon as all the sap is extracted the old plant dies entirely, having performed all that Nature intended. We have a visible proof of continued growth in the portions of the bulbs I have now submitted to you, as it is easily seen that they have been growing and increasing in size all the winter. We have another proof of the continued vigour of the new bulb in *L. candidum*. In the autumn, while the old stem is dying down and perishing, the new bulb is pushing up aboveground a cluster of leaves, which continue fresh and green during the winter. This has given rise to the mistaken idea that *L. candidum* is an evergreen; it is, however, no more evergreen than any other Lily. Allow me, in conclusion, to thank Mr. G. F. Wilson for his evidence (see p. 188) that "the bulb of *L. giganteum* unmistakably dies after flowering, and that in some of the North American Lilies it can only be the young bulbs which flower." DUNEDIN.

ANEMONES.

THE ANEMONES are a large family, containing about seventy species, and of all the seventy we may safely say that each is worthy of a place in any garden. In Great Britain we have only three of the family—*A. nemorosa* (and its many varieties), *A. apennina*—both excellent little plants to grow in shade or shrubberies, though they will grow equally well in more open spots—and the beautiful *A. Pulsatilla*, or Pasque-flower. This must be grown in a more sunny spot, and is somewhat particular about soil. As a wild flower it grows on chalk, but this is not absolutely necessary; it will grow in any good garden soil that is not wholly stiff clay. When well grown, the garden plant is far superior to the wild one, and is one of the loveliest of our late spring flowers. But of all the Anemones there are probably few that are more strikingly handsome than the *Anemone fulgens*. It is a native of the south of Europe, and is especially abundant about Mentone from shore-level to about 600 ft. elevation, and where, according to Moggridge's "Flora of Mentone," it is confined to cultivated ground, and becomes a troublesome weed. It is not a true species, but is a variety of *Anemone hortensis*. It seems also to vary in some few particulars. The flower in the plate (see p. 214) has its petals entirely scarlet, and so it is certainly found; but I have also seen it in gardens as it appears in Mr. Moggridge's plate, with yellow in the lower part of the petals, and with yellow anthers. Its cultivation is most simple; in good soil it may be left undisturbed for years, and is probably better for being left alone. In poor soil it would be benefited by being taken up and

divided and the soil enriched; but whenever taken up it should be returned to the ground speedily. Anemones will bear having their roots kept out of the ground a long time, but there is no good result from this, unless when it is wished to prolong or alter the time of flowering. The usual time of blooming for *A. fulgens* is from the end of February to April, and in good soils and in good seasons the colour of the flowers is very brilliant. HENRY N. ELLACOMBE.

Bitton Vicarage.

Spring-blooming Annuals.—Two or three of these deserve special mention on account of their undoubted vernal beauty. One of these is the charming *Collinsia verna*, but it is seldom met with. I have never seen it in better condition than in Mr. Barr's grounds at Tooting, where it is used as a kind of margin to bulb beds. The seed should be sown thinly in lines soon after it is gathered; in due course it will germinate, and being of a very hardy character it stands the winter and flowers along with the Daffodils in spring. It is said that its seeds will not germinate unless sown soon after they are ripe. *Collinsia violacea* is a later introduction, which, like *C. verna*, should be sown in autumn to bloom in spring. It is a very decorative annual, but nevertheless it is not a favourite. Then there is the exquisitely charming *Leptosiphon roseus*, one of the most lovely of dwarf, spring-flowering annuals. It should be sown in autumn by casting a little seed over the bed and then thinly surfacing it with fine soil. It will grow freely, and in spring form a carpet of a delicate, soft, pinkish blush. It is one of those useful flowers that should find a place in every garden.—D.

Double Blue Hepatica.—"Inquirer" asks (see p. 232) how to grow this charming spring flower. Like him I never could induce it to live till I hit upon the following simple mode of treatment, under which it thrives and flowers as successfully as can be desired:—I have all the plants of it potted in ordinary garden soil, taking care to keep the crowns well aboveground. In autumn the pots are plunged in a cold frame, and there they remain till after flowering in spring. When the hot weather of summer comes, the pots are placed under a north wall, where the sun never reaches them, and they are watered occasionally as required during dry weather. There they remain till the time for removing them back to the cold frame has arrived. I treat several kinds of hardy *Cyclamens* in the same way, and they equally appreciate the little extra attention thus bestowed on them.—G. F., *Bellingham*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Size of the Scarlet Wind-flower.—With reference to the size of this as compared with other Anemones, it is not so much from it surpassing them in size occasionally that makes it so distinct in aspect and so valuable, but from the fact that its flowers are so fully and boldly spread. The result of this is that even on harsh days in early spring it is as effective as the most brilliant flowers of the summer garden.—E. F. ELLIS.

Imported Bulbs.—In reference to these, one fact must be decidedly clear, viz., that under our enormous annual importations the whole country would soon be a bulb garden, if the bulbs did not speedily die out, the cause of which must be attributed to the drying off process, the pernicious effects of which are annually everywhere visible.—J. GROOM, *Henham*.

***Centaurea rutefolia*.**—This new and distinct species will probably find a home in our flower gardens. It is a native of the Balkan region, and is said to form a handsome silvery pyramid when in flower. It will probably prove hardy in dry soils in winter. It has, I believe, been sent out by Messrs. Froebel, of Zurich.—J. G.

Culture of *Desfontainea spinosa*.—I should be very grateful if you could tell me what is the right treatment for this plant. I have seen it very fully covered with flower in Scotland, but I can find no one in England who grows it successfully.—L. P.—[The *Desfontainea spinosa* will grow in any ordinary garden soil that is not too heavy and cold. It thrives best, however, in a mixture of peat and loam in equal proportions, or with a preponderance of peat rather than otherwise. In such a soil, well supplied with moisture during the growing season, and protected from cold winds blowing from north, north-east, and east, it will flower profusely; and although not a rapid grower, it forms a very handsome and compact evergreen bush. The finest specimens with which I am acquainted are in Devon and Cornwall.—V.]

***Rafflesia Patma*.**—Those of your readers who may be interested in that curious Sumatran parasite, *Rafflesia Arnoldi* (see p. 239), will find another yet more conspicuous and extraordinary species of this singular family (not mentioned by your correspondent), bearing the name of *Rafflesia Patma*, fully described, and accurately figured in two most beautifully executed double coloured plates, wherein all the stages of the flower's development, from its first appearance as a bud, somewhat resembling a Button Mushroom, up to its full expansion, are given in vol. 15 of Van Houste's beautiful work, "Flora des Serres et Jardins de l'Europe," l. 13-16.—W. E. G.

AGES AT WHICH TIMBER TREES MAY BE MOST PROFITABLY FELLED.

TIMBER trees are planted with the view of profit being derived, either directly from the sale of the timber, or indirectly by giving shelter to stock and crops, and increasing the value of an estate by adding to its amenity. But in this short account I shall confine my remarks to trees yielding profit from the sale of their timber, as trees grown for shelter or ornament, or partly for both, are generally allowed to grow beyond maturity before being felled. At the outset it may be observed that much depends on management whether the planting of trees will turn out a profitable or a losing investment; and whatever may be the kind of trees or the soil in which they grow, their general management in judicious pruning and thinning on the one hand, or total or partial neglect on the other, will have much to do with the age at which they can be most profitably cut down. When trees neglected in their youth are drawn up and branchless, except within a few feet of the top, in consequence of overcrowding and want of judicious thinning, they become prematurely ripe before reaching half the normal age and size. In such cases the most profitable system would be to fell the whole at once, and replant the land, as after trees pass a certain stage thinning is of little avail, and a loss and waste of time results from any attempt to improve them by changing the management. But even with careful treatment and thinning from the first the results are different as regards the age at which trees should be felled, the quantity and quality of the timber, and the revenue to be derived by the proprietor therefrom. Thus, it occasionally happens that trees in the same plantation, and in the same soil, do not arrive at maturity simultaneously—one tree becoming mature, it may be, when eighty years planted, while another close by may not reach the same stage before one hundred years; but such is the exception and not the rule, as in well managed plantations trees in the same kind of soil generally attain maturity about the same time, although they may vary much in size. It is stated by some that Scotch Fir, Larch, and Spruce, can be most profitably cut at from twenty to thirty years of age, when growing in a locality where they can be disposed of for mining purposes; but I have not found this to be the case in my experience in the management of plantations within fifteen miles of large coal mines. In such a locality, when the price of prop-wood is high, it will almost invariably be found that proportionally high prices will be obtained for larger timber; while if the plantations be far from a market or a railway-station or sea-port, the crop at that age would not be worth the planting, cutting, and removing, and would therefore be a dead loss to the grower of from twenty to thirty years' rent of the land. Further, it would not pay to cut down trees of the above description for fencing and estate purposes, because these can easily be supplied from the thinnings of well-managed plantations. It has already been remarked that, as a rule, timber trees should be allowed to grow to large dimensions before being cut, but the situation in which they grow often necessitates a different course. For instance, in glens and mountainous districts, and in places inaccessible to horses, the most profitable management would be to cut them down before they arrive at a size too large to be removed in entire lengths by manual labour. At that early stage Fir trees would be valuable for prop-wood, fencing, and other estate purposes, Ash for handle-wood, and Birch or Alder for charcoal or bobbin-wood, &c.; whereas, if allowed to grow to a large size, they would have to be cross-cut in lengths to admit of their removal by men, and this would, in the first place, make the timber useless for many purposes for which it might otherwise have been valuable; and secondly, the expense of removal by manual labour might equal, or

even exceed, the value of the timber itself. When Scotch Fir, Larch, or Spruce, have been planted as nurses for hard-wood trees, they should be thinned out as soon as they begin to encroach on the trees intended for the main crop, as this is necessary for the welfare of the plantation, irrespective of the value of the thinnings. But when such trees are planted as the future crop on suitable ground, it will almost always be found most profitable to allow them to attain timber size. The Larch being of fast growth, and useful for various purposes at an early age, can be cut down profitably much sooner than the Scotch Fir. Oak is extensively used for ship and boat building purposes, furniture, agricultural implements, &c., and is longer than any of our forest trees in arriving at maturity. It can never be cut down so profitably when small as when well matured and having plenty of heart-wood. When young, and with little heart-wood, and a large proportion of sapwood, the timber is of comparatively little value per cubic foot, so that it can seldom be cut down profitably, especially if thriving on soil suitable to its growth, until it reaches 100 years old. Of course, when grown as copse-wood, it ought to be cut young; but even under the most favourable circumstances in Scotland copse-wood is less profitable to the proprietor than a crop of timber, and Larch can be grown more profitably in most situations. The Oak is of slow growth when young, but on suitable ground it increases rapidly after about thirty years. It sometimes happens that Oak, planted in good soil and in a sheltered position, attains a large size, but has little matured heart-wood at sixty or

Acauthus latifolius (see p. 263).

seventy years old, and in such a case it would be better to allow it to remain till fully matured, when the value of the timber per cubic foot would be materially enhanced. The Ash, although capable of growing to large dimensions, can be cut down more profitably in its young state than other hard-wood trees. When clean grown, and from thirty to forty years of age, it is in great demand for handle-wood, and for agricultural implements; but in a rich loam, with dry subsoil, it would be more profitable to allow it to grow to double that age. The Alder is generally in good demand at all stages of its growth, after arriving at sizes suitable for the clogger, and for turnery, or charcoal, and is seldom grown to very large dimensions. Thriving best in damp soil, it can be profitably cut down at forty years' growth, making way for a second crop, which springs up rapidly from the stools. The Beech is of little value in its young state, and is seldom cut till well grown. Birch, like the Alder, can be cut down profitably at about forty years old, being then in good demand for cloggers, charring, and turnery purposes, and when of large size and good quality it is extensively used for furniture. Horse Chestnut is seldom planted for profit, but is valuable as an ornamental park tree. When grown on good soil and in a sheltered situation, however, it can be profitably cut down when it attains large dimensions. Spanish Chestnut is of most value when of large size, and is in many cases used for the same purposes as Oak. It is most profitably cut down when about 100 years old. Elms (Scotch and English) are of little value until they have arrived at timber size, and should therefore never be cut as a crop until they are from eighty to one hundred years old. When on good soil, the English Elm will, when matured, be of large dimensions. The Scotch Elm seldom attains so large a size as the English Elm, but its timber is of more value when matured, and forms heart-wood sooner. The Lime tree, like the Horse Chestnut, is seldom planted for profit, but when of large size it is in great demand for brake blocks for railway purposes, &c. It is, however, of little value before it is sixty years old. Poplars can generally be most profitably sold when about fifty years old. Being very fast growers, they arrive at timber size sooner than most of our timber trees, and the wood is then much used for brake blocks,

boarding, &c. When of small dimensions, the wood of this tree is of little value. Sycamore and Norway Maple, although in demand for turnery purposes when of small size, can seldom be cut down to full profit, until they have arrived at maturity and attained large dimensions, when high prices are obtained for them for printing blocks, &c., and larger timber becomes proportionately more valuable. When the Sycamore is planted in a good soil, well drained and sheltered, it may be profitably cut down when it is about 100 years old. The Willow, like the Poplar, is a fast grower on suitable soil, and can be cut down profitably about sixty years old, and for its timber there is a good demand. Gean tree or Wild Cherry, Holly, and Laburnum are grown more for ornament than for profit, though in some instances good prices can be obtained for their timber. The two latter seldom attain a large size, and may be felled any time when in demand after attaining a size suitable for turnery. In consequence of its hardness and saseptibility to receive a fine polish, the wood of these trees is much sought after. The Walnut, when matured, is much esteemed for furniture, &c., but is of little value in its young state, and is generally planted for its fruit or as an ornamental tree.—“Arboricultural Society's Proceedings.”

Cedars in Algeria.—A friend writes from Algeria as follows:—
“The seeds which I send you are from the Cedar trees at Peniet el Hâd.

its use indoors as a window plant, and out-of-doors as a fine-leaved, herbaceous plant. It is one of the most valuable of plants for planting in isolated tufts on the turf; so placed in good soil, it in a few years forms a luxuriant mass of leaves that are individually large, fine in form, and of a deep glossy green.—V.

EARLY CABBAGES RUNNING TO SEED.

As usual, after a mild winter, complaints are everywhere rife of the early crops of Cabbages and Cauliflowers running to seed instead of forming hearts. When crops “bolt” in summer we ascribe the cause to a check of some kind; drought, intense heat, or keeping young plants too long in the seed-bed, all have a tendency to cause premature growth under certain circumstances; and no doubt the cause of early Cabbages “bolting” at this season is due to the tops getting in advance of the roots—ontrunning the supplies, in fact—a check is thus sustained, and the plants rush into flower when they ought to be forming hearts. Cabbages, like other biennials, if sown very early, will always be more or less liable to “bolt.” And this propensity is influenced in some degree by the season, soil, the kinds grown, and the purity and care with which the stock has been saved. The two latter items are not always taken into account in our efforts to trace effects to their true causes, but I am convinced their influ-

A mile from where we are staying rises a noble mountain 1600 ft. high, whose slopes are covered with magnificent Cedar trees much larger than the Cedars of Mount Lebanon, some of them measuring 33 ft. in circumference. There appear to be two kinds of Cedars on the mountain, and the snow which has just fallen only makes the same more glorious. Juniper bushes, as big as Apple trees in Sussex, grow among the Cedars, and later in the spring, we are told, the ground is carpeted with flowers. We are just off to Batora, in the province of Constantina, and are taking tents and provisions for camping out.” If any of your readers have seen the Cedar trees of Algeria, would they tell us something of their growth and varieties. Whether the Cedrus atlantica will ever grow into as fine an old tree as the Cedar of Lebanon, and whether both are really distinct from the Deodar of the Himalayas are questions of deep interest to all who love trees, especially Cedars. JUVENIS.

Acanthus latifolius.—This noble herbaceous plant is slowly making its way among us. During the past winter we frequently noticed the perfectly fresh glossy green of its foliage amidst the surrounding bareness. It is the hardiest of all the Acanthuses, according to some observations made in M. Vilmorin's garden near Paris. The hardness referred to here means that of the foliage; all the species in cultivation in the open ground are hardy at the root. The plant figured (see p. 262) is precious from a double point of view—

ence is not small. Some varieties are less excitable than others, a fact which I have frequently proved. It is a very rare occurrence for the Enfield Market to “bolt,” even when sown early. Atkins's Matchless may also be taken as a very good representative of the small early section, that cannot easily be beaten for general purposes; and this season the two kinds I have named are as free from runaway plants as usual, which is more than can be said of some of the other kinds. The best way in which to treat the runaways is to cut the tops and use them; pull up the stems, and plant others from the reserve seed-bed; or, if they are in greater numbers than can be used at once, dibble in the fresh plants beside those which they are to replace. No doubt this has been an exceptional season, and the only way to be prepared is—in the matter of Cabbages and Cauliflowers—to make two or three sowings at intervals of eight or ten days, and to give the preference to such varieties as we have proved under all conditions to be trustworthy, giving due weight at the same time to the latitude of each place, and its influence upon the climate and other conditions relating to growth. E. HOBDAV.

Spent Tan as Manure.—This has been recommended by several correspondents of THE GARDEN as a manure, and in different ways. In a somewhat dry state I find it very valuable in absorbing liquid and gaseous matters when mixed with half liquid manure. In this way the manure is deprived of its offensive appearance and smell,

while its best properties are preserved. This mixture, applied as a top-dressing during the winter and spring months to the ground on which Cauliflowers and Cabbages are grown, produces a wonderful effect, and by its assistance I am enabled to grow fine, succulent examples of these vegetables, as well as Brussels Sprouts, Savoys, &c., on soil extremely thin and poor, and which produces very poor specimens if treated in the ordinary way. When it can be obtained in quantities from the tan works, it makes one of the best and cheapest materials for mulching known; but it is decidedly preferable to use it in a decayed state only. It may not be generally known that fresh tan and stable litter mixed make a hotbed very much superior to stable-yard manure alone, and even superior to one of litter and leaves; for Cucumbers and Melons I always use tan and litter in equal proportions, and I find that the mixture suits them admirably.—ALEXANDER HONEYMAN, *Hope Park*.

Gas Lime (see p. 199).—I have found that if I use gas lime in too large a quantity, it kills all vegetation for the year during which it is applied, and I believe all the wireworms and slugs as well—a purpose for which it was principally intended. A covering of it, half-an-inch in thickness, would probably do no harm, letting it lie on the surface a week or two before digging it in, and then mixing it well with the soil. The best and safest way, however, of using gas lime is mixing it with a large proportion of soil, and letting it lie for a year in a heap, and then using it as a compost for top-dressing light soils, or for digging it in strong soils, in order to disintegrate them.—WILLIAM TILLERY, *Welbeck*.

Pearson's Plan of Glazing.—We are surprised to learn (see p. 21) that the breakage by frost has been considerable in houses glazed with glass cut as recommended by Mr. Pearson, and think that it must be the result of either the glass being improperly put in, or its not being thoroughly annealed. Since this system of glazing was introduced about ten years ago by the late Mr. J. R. Pearson, we have always adopted it for the roofs of houses which we have built, and it has given universal satisfaction. We make the glass overlap a quarter of inch; more than this is useless, and causes breakage in winter or affords a place for dirt and conservæ to accumulate in summer. Much, however, of the breakage said to be caused by frost, is the result of the glass being fitted in too tightly between the woodwork, when it is of course broken if the latter swells at all with damp. We are sure that not only will there be less breakage in houses properly glazed on this system, but that the houses themselves will last much longer, and we strongly recommend our readers to adopt it.—FOSTER & PEARSON, *Beeston, Notts*.

ROYAL HORTICULTURAL SOCIETY AND GUINEA FELLOWSHIPS.

HAVING on the 10th written a "last" letter on this subject, I hardly venture to trouble you with another; I believed that the matter would have to rest for a considerable time, but circumstances have changed. The day after my letter was sent came an answer from the President. His Lordship's accident had prevented his getting up to the Council. His views as to the policy of the Society in the future are, to my mind, entirely satisfactory. Then there came a well-known amateur horticulturist from Clifton, who considers that it is so great a gain having the guineas admitted in any shape, that we ought to be satisfied for the present, and to make the most of what we have got. Then a good representative of another section of horticulturists, Mr. Gilbert, gardener to the Marquis of Exeter at Burghley, wrote exactly to the same effect in a contemporary. Both these opinions carry weight. Some of our correspondents will not join the present Society; others will not join it while it has the maintenance of the garden at South Kensington; but I believe that by far the largest number will trust to us on the spot, knowing that our only object is the promotion of horticultural science, and will act as advised. I think if the Fellowship, with a vote for those living outside London had been proposed at the general meeting, it would have been adopted, and I take great blame to myself for not having thought of this. It is now too late for this year, but I think, and have reason for thinking, that if a large number of country horticulturists will join the Society on the terms now offered—that is, membership without a vote, for a guinea subscription—that we have good hope of getting the vote hereafter. Happily, the tickets attached to the two-guinea subscription having now been made transferable, there is sufficient difference in value between this and the non-transferable ticket given to the guinea subscribers. On the whole, then, I would advise those who have given their names as would-be guinea Fellows to accept the guinea membership, and think that both the influx of a large body of country horticulturists will strengthen and improve the Society, and besides that, their guineas will be applied to horticultural objects. Those who come up to London will have full consideration for their money, as, judging by the shows on the days of the committee meetings which have been held this year, both leading nurserymen and amateurs have determined on exhibiting so many Orchids and other beautiful flowers and plants, that the shows now held the first and third Wednesday of the month are

well worth the subscription. I have only to add that it is to be hoped that those who come in will bear in mind that the greater the number of guinea members, the greater consideration they will receive, and that all will try and influence their friends to follow their example. In this neighbourhood, where our canvass was completely successful, the principal argument used was, "You take delight in your garden, we only ask a guinea subscription; will you not give this (or find a substitute) to promote the science which improves gardens?" Now that Mr. Veitch has set the good example of opening a list for Fellows and Guinea Members, it is most desirable that other nurserymen—not only in London, but in the country—should follow his example; they would get their reward. Horticulture cannot be promoted without at the same time increasing the demand for plants.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

Wimbledon Gardeners' Improvement Society.—The last meeting of the season of this association was held on Monday last, when Mr. Ollerhead read another portion of his paper on Vine culture, which created considerable discussion, particularly as to airing, setting the fruit, and watering the borders. At the close of the meeting a vote of thanks was accorded to Sir Henry Peck for the interest which he has taken in these meetings. This association is the parent of what is termed the Wimbledon Club Society, that has been established at the village Institute, the members belonging to which at the present time number about seventy; they meet in the Lecture Hall every fortnight for debate, and, apart from discussions, they have established a circulating library consisting of 130 volumes.

OBITUARY.

We have to announce with regret the death of Mr. Thomas Dickson, an event which occurred on Friday morning, the 23d inst., at Upton, Chester, in the forty-second year of his age. The deceased was the youngest son of the late Mr. Francis Dickson, the founder of the well-known firm of Messrs. F. and A. Dickson & Sons, of which Mr. Arthur Dickson is the head. In private life Mr. Thomas Dickson was much respected, and his loss will be felt by a large circle of friends. Until recently he took an active part in the management of the nursery department of the business.

NOTES AND QUESTIONS—VARIOUS.

The Wallflower as an Indoor Plant.—I have lately been pleased to see how well the Wallflower does in cool, well-lighted windows, and I recommend it to those interested in advancing window plant culture among the poor. In one small house I entered the odour was delicious that came from a fine Wallflower growing in a rough wooden box.—J. E. ELKINGTON.

Fruiting of *Ruscus androgynus*.—Growing on the back wall of the conservatory here was a large plant of *Ruscus androgynus*, which I was obliged to pull down. At the very back of the plant I found a single fruit. It never fruited here before, and from inquiries which I have made, I believe it to be the first time in which it has fruited in this country. Perhaps some of your correspondents might know of its having fruited before.—F. W. MOORE, *College Botanic Garden, Dublin*.

Hip-roofed Houses or Pits.—Permit me to ask Mr. Groom (see p. 19) to give the dimensions and a section of the pits lately erected by him at Henham. I am of opinion that for general purposes houses or pits of the shape alluded to by him are the most useful that can be put up, especially if sunk below the ground-level somewhat. When put up by a practical man like Mr. Groom, a few notes as to how such houses are managed, are sure to be useful.—C. J. H.

Manuring Raspberries.—Those who wish to grow good Raspberries should do as the market-garden growers are now doing—give their plantations a heavy mulching of rotten manure, which will shortly be carefully pricked in with a fork. The value of this practice is apparent when the enormous crops which market growers obtain are taken into consideration, and these even from plants growing under fruit trees.—S.

Large-fruited Almond (*Amygdalus macrocarpa*).—Well-established trees of this are now very attractive in Mr. Parker's Nursery, at Tooting. The fully expanded flowers which are pure white, with golden-yellow-tipped anthers, are as large as a crown piece. This is one of the most showy varieties of Almond, small sprays covered with blossoms being very effective when used among other flowers in vases or bouquets. Small plants are equally as floriferous as large ones, bearing blossoms and buds in great profusion on every young twig. C. S.

Vines Late in Breaking.—I have a Vinery under my charge in which six different sorts of Vines were planted four years ago in a well-made border; but neither Lady Downes nor Muscat of Alexandria seem inclined to break. What is the reason? I started them a month ago. The names of the Vines are Buckland Sweetwater, Black Hamburg, Black Alicante, Muscat Hamburg, Muscat of Alexandria, and Lady Downes.—WM. PALMIST. [In the list of Vines planted, the two last-named varieties, viz., Muscat and Lady Downes, are generally very slow in breaking, and if not done so, should have been planted in the warmest part of the Vinery. There need yet be no fear of their breaking, provided nothing is wrong at their roots; and I should bring them down from the rafters, and keep them in as low a position as possible, syringing them daily. I have a large Vinery in which Muscats, Buckland Sweetwaters, Trebbiano Hamburgs, and Alicante are planted, and the Muscats and Trebbianos were at least a fortnight later in breaking than the others.—W. TILLERY.]

National Rose Society.—In our last week's number it was stated (see p. 23) that £25 were to be awarded by this Society in prizes. It should have been £20, the cypher having dropped out in the passage of the paper through the press.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

ROSE SAFRANO.—Two plants of this Tea Rose, on the back wall of a lean-to Vinery, have been greatly admired by every one who has seen them during the last three weeks. They are on their own roots, were planted two years ago, and at the present time each Rose covers a space of about two square yards. They have never ceased to bloom, more or less, since last September; and I do not think there was a week during the winter in which I could not have supplied a few buds. The Vines were started early in January, and at that time the Roses were slightly cut back, thoroughly cleaned with soap and water, and replaced on the wall. In a few weeks they commenced to "break" from almost every eye, and for the last three weeks they have been, as I have stated, covered with blooms, which have come in very usefully for Easter. I have cut over six dozen since Friday last, and there are many more still to cut. Another tree of the same variety which is on the back wall of a Peach-house will be coming into bloom in about a fortnight, and will keep up a supply of cut Roses almost until those in the open air begin to expand. The great merit of this Rose is that it is easily forced, and is seldom or never affected with mildew, though owing to the nature of our soil, we are very much troubled with this fungus. I top-dress annually with about 2 in. of equal parts loam and horse-manure, a mixture which is applied more for the benefit of the Vine roots than the Roses; and as they receive copious supplies of water, both overhead and at the roots, we are seldom troubled with insects.—H. H.

THE PARIS FLOWER MARKETS.—In addition to the white forced Lilac, very small plants of the Persian Lilac are now seen in the Paris flower market. They are not more than 15 in. high, and are full of flowers. The old Bottle-brush plant (*Metrosideros*) is grown for the markets of the French capital, and is very bright and distinct from the other flowers. Cactuses of the Ackermanni type are also grown for the sake of their large flowers. Prettiest of all, however, are the small oval baskets crammed with large flowering Pansies, which never look happier than in these simple baskets. There are four principal flower markets (not to mention various minor ones), each market being held two days a week. An immense quantity of flowers is produced for these markets, which are very interesting at all seasons. They recall Mrs. Browning's lines:—

Went out at early morning, when the air
Is delicate with some last starry touch,
To wander through the market place of flowers
(The prettiest haunt in Paris), and make sure
At worst that there were Roses in the world.

TWO GOOD DAFFODILS.—*Narcissus Horsefieldi* and *N. Empress* are two of the best Daffodils now in bloom. The first-named variety was raised by a poor Lancashire weaver about twenty years ago, and is a large and fine form of the white, golden-crowned *N. bicolor*. *N. Empress* is a seedling raised by the late Mr. W. Backhouse, of Walsingham, and is undoubtedly the finest of all the bicolor section of *Narcissus*, having stout glaucous leaves fully an inch broad. As seen in masses just now in Mr. Barr's and Mr. Ware's collections of hardy bulbous plants, these plants are the most stately and beautiful of all hardy flowers.—B.

GARIBALDI STRAWBERRY.—Good punnets of this Strawberry are still being brought into Covent Garden market by Mr. Bennett, of Rabley; the fruits are of fair size, and equal in colour to Strawberries in May. The plants on which they are produced were grown from runners last summer brought gradually on, and some 200 of them are now loaded with fruits which, when placed side by side with Keen's Seedling, show a decided advantage both as regards cropping qualities and appearance.

ILL EFFECTS OF MARCH FROSTS ON SPRING FLOWERS.—The frosts of last month have been severe in Worcestershire. We began with 15° on the morning of the 1st, and have since had 12°, 11°, 10°, and 8° frequently. The damage to spring-flowering plants has been considerable; early Primroses and *Myosotis dissitiflora* have had their blooms quite destroyed, while tree *Pæonies* appear to have been killed outright in exposed situations. I have also lost some fine plants of *Aquilegia cœrulea*, which had wintered only too well, and started into growth. Herbaceous *Phloxes* have also suffered, while Pansies and *Violas* are looking very miserable. I consider *Myosotis dissitiflora*

quite needless here—warm February days quicken it into precocious bloom, which March winds and frosts promptly destroy. The *Aubrietias* have gone through the ordeal bravely, and are loaded with buds just on the point of expanding. Of Pansies Cloth of Gold has behaved the best. Wallflower Belvoir Castle has also defied the frost, and promises to bloom abundantly.—H. M.

HOTBEDS IN FLOWER GARDENS.—At present as the leaves and various protecting materials are being taken from the half-hardy plants in the Parc Monceau, they are collected into some of the large beds (emptied of earth), and formed into gentle hotbeds on which to plant the large-leaved *Caladiums* by-and-by. The fact may be worth recording in the interest of those cultivating such plants in the open air; but we are convinced that there is no real progress in the so-called sub-tropical gardening. There are thousands of beautiful plants perfectly happy in our climate without hotbeds or expense. The plants, moreover, have as graceful or as stately foliage as any other, therefore they demand our best attention, and will best repay it.—V.

ELÆOCARPUS DENTATUS.—A specimen of this ornamental spring-flowering greenhouse shrub, so rarely to be met with in gardens, is now finely in flower at Messrs. Osboru's, Fulham. The plant, which is growing in a large pot, is 6 ft. or 8 ft. high, and 3 ft. or 4 ft. through, and is literally covered with fringed white, bell-shaped blossoms, which last in bloom for a long time. It is a plant that well deserves much more attention than it at present receives.

ILLICIAM RELIGIOSUM.—This somewhat rare evergreen shrub is now in bloom on a wall in Messrs. Veitch's nursery at Chelsea. Its flowers, which are of a creamy-yellowish colour, are borne thickly in small clusters of twos and threes up the sides of the branches, and form a fine contrast with the glossy green leaves. In Japan, where it is associated with religious ceremonies, it grows to about the size of an ordinary Cherry tree.—S.

AKEMIA QUINATA.—This has been flowering beautifully here in the open air during the last fortnight, and promises to continue in good condition for several weeks to come; its usual time of flowering is April. It is one of our best evergreen climbers, and although generally classed among greenhouse plants in nurserymen's catalogues, it is quite hardy. The flowers are also sweet-scented, and the foliage handsome. It should have a south aspect if it be expected to flower well. It occasionally, but rarely, produces seed in large, fleshy, singular-looking pods.—JOHN GARLAND, *Killerton, Exeter.*

STREPTOCARPUS SAUNDERSI.—This is rarely met with in private gardens, and indeed it does not appear to be common even in London nurseries. A plant of it in Mr. Parker's nursery at Tooting is now bearing several spikes of flowers, which are pure white with a delicately-tinted sky-blue throat. Among Gesnerads this certainly deserves a permanent place.—W. S.

CLEMATISES IN CONSERVATORIES.—Amongst Clematises for conservatory decoration none surpasses in beauty or usefulness the double-flowered pure white *Lucie Lemoine*. Several plants of it, trained as pyramids, are now finely in bloom in Messrs. Veitch's nursery, Chelsea, where, associated with kinds possessing other colours, they are very effective. For the spring decoration of the conservatory or greenhouse such plants as this are invaluable.—H. C.

PRIMROSES IN EASTER DECORATIONS.—Amongst all the flowers now so extensively employed for church decoration at Easter, none are more effective than common Primroses, when tastefully arranged in bunches associated with their own foliage, and inserted in beds of green Moss. Seen under such conditions they have a natural and therefore pleasing effect, unsurpassed by more costly materials. For flat decorations such as those used in windows, or as an edging to the font we use them largely, and if the Moss be kept damp, they last in good condition for a long period. This season they are exceptionally early, fine, and abundant.—JAMES GROOM, *Henham.*

GAUNTLET PELARGONIUM AS A WALL PLANT.—The back wall of a lean-to plant-house in the Rabley nurseries covered with this *Pelargonium* now affords an interesting sight. The plants are grown in pots plunged in the border into which the roots have penetrated, from which they derive their principal support. All the attention which the shoots receive is simply that of tying in new growths as fast as they are made, and occasionally removing decayed leaves, and nearly all through the year they are a mass of buds and blossom, the latter large and remarkably bright in colour.—J. S.

CACTI AND SUCCULENT PLANTS.—Doubtless many who have seen and admired the pretty miniature specimens of Cacti and other succulent plants sold in Covent Garden and elsewhere have wondered whence they came, seeing that they are not to be found at ordinary nurseries. The fact is, this branch of gardening industry was a monopoly, having for years been carried on at 73, South Row, Kensal

New Town, London, and also in Paris by the late M. Pfersdorff; since the death of the latter the business has been taken up by Mr. J. Croucher and Mr. H. Boller, both of whom are adepts in the culture and nomenclature of these singular plants. Mr. Croucher is well known as our best practical authority on succulent plants of all kinds, and we hope his new venture, as regards their sale, will prove to be a successful one.—B.

MAGNOLIAS AT FULHAM.—Several specimens of *Magnolia conspicua* may now be seen in full bloom in Messrs. Osborn's nursery at Fulham. They are from 12 ft. to 15 ft. high, and as much through, and their blossoms, which may be counted by thousands, are deliciously fragrant.—J. S.

BEGONIA SAUNDERSI.—This *Begonia*, which is probably unsurpassed by any of its class for spring flowering, does not appear to be nearly so much grown in private establishments as might be expected. Fine bushy plants of it struck from cuttings during the summer are now used in the Royal Aquarium and are literally loaded with drooping trusses of pink and scarlet blossoms, and, associated with *Spiræas*, *Deutzias*, and other flowering plants, are exceedingly effective. For the decoration of the conservatory this *Begonia* can scarcely be too extensively grown.

MAY BLOSSOMS FOR EASTERTIDE.

Of all the flowers that enrich Easter decorations May blossom is to my mind the most pleasing and suggestive; it is simple, pure, sweet. The size of the flowers bunched up so admirably for decorative purposes, with their chaste greenery of tender foliage, is all that can be desired. Hawthorn bloom is in my opinion superior for Easter decorations to Camellias (that suggest winter rather than spring), *Rhododendrons*, *Azaleas*, or other gorgeous tropical flowers. But how, it may be asked, can May be had in flower at Easter? Few things can be easier. The May bears gentle forcing well; plants from 3 ft. to 6 ft. in height should be potted from the open ground, say in 12-in. pots, at the end of October or early in November. Any soil will suit them, as the Hawthorn is by no means particular in that respect; a sandy loam is as suitable as any other. After potting, water thoroughly to consolidate the soil and settle the plants in their pots. Place them, if convenient, in a sheltered situation against a fence or wall and attach them firmly to such support, or place a stout stake to each to keep tops and roots immovable in one position. Mulch the surface of the soil over with an inch or two of rotten leaves or litter. This is to encourage the formation of fresh roots, and also to protect them from frost. This may seem superfluous with such a hardy plant as the May; but it should be remembered that the hardiest of plants are only hardy under natural conditions. Hence May in pots should have a frost-proof covering not only over the surface, but also round the sides of the pots as the weather becomes severe; this last is afforded by plunging the pots to their rims in the ground or in some frost-excluding material. These matters form important preparatory steps to the safe forcing of the May. The plants may be introduced into heat in batches of half-dozens or dozens from the month of December to March, according to the quantity and season at which the blossom is required. For all the earlier batches two months must be allowed for getting them into bloom; for midseason supplies, six weeks will be ample; for later ones, three weeks or a month will suffice. Such are the wide differences in regard to time between forcing out of season and urging on plants a little in season. It will also be seen that May does not like sharp forcing; in fact, it will not withstand it. A dewy atmosphere, with a temperature ranging from 55° to 65°, suits it best. As soon as the plants are in flower, they should be removed to a cooler temperature; a conservatory or greenhouse suits them admirably. They should, however, be dewed overhead at least night and morning, to keep them fresh. The May does not become tarnished by clear water, as some delicately-coloured blossoms do. The plants also last long in bloom in cool rooms, halls, and on staircases. Standard, pyramidal, or bush May trees are also admirable for other kinds of decoration and prominent positions in churches. The flowers have also good staying qualities when cut, especially the double ones, which are admirable for dinner-table designs, bouquets, and wreaths, and as for button-holes, about three sprays of Scarlet May as a base for a sprig of *Forget-me-nots* is as near perfection as may be at Eastertide. After flowering, plunge the plants in an open situation out-of-doors, sinking the pots 2 in. below their rims. This saves much watering in summer, and keeps the roots cool; in fact, unless during abnormal droughts, the plants will need no water at all when in the open air. Plants treated thus have been in the same pots for about six years, and have been forced every year, and still they are as healthy and more floriferous than ever. Of course, they flower better the second year than the first, as they are better

rooted and more thoroughly established. But Thorns in pots continue healthy for many years in the same soil without any manure-water or other feeding. No insect ever attacks them nor mildew, and they yield a maximum amount of pleasure at a minimum expenditure of labour and skill. I have often wondered that the Hawthorn is not universally forced for Easter and other decorative purposes; it is as worthy of this distinction as the Lilac, the *Deutzia*, the Lily of the Valley, or the Rose.
D. T. FISH.

Mistletoe on a Scotch Fir.—I have seen Mistletoe, I think, growing on all the trees enumerated lately by your correspondents except the Oak, on which I have never been fortunate enough to find it. The Scotch Fir, however, is not among the trees mentioned on which it grows, and it may interest some of your readers to know that I gathered it on this tree many years ago in the Bavarian Tyrol, between Munich and Innsbruck. It grew by the roadside in one spot, in an abundant colony; the plants were large and vigorous, and evidently in a thriving condition. I was amazed to find an old friend, which I had always been accustomed to see fed on the sweet juices of Apples and Poplars, thriving equally well on the anstere turpentine of a Conifer. To prevent any chance of mistake, I cut off a branch and brought it home with me. It was a curious example, showing the perfect union of the two plants.—J. D. LLEWELYN, 39, Cornwall Gardens, Queen's Gate.

Hybridizing Alpine Silenes.—Having obtained from Messrs. Backhouse a plant of the charming *Silene Hookeri* imported by them from Oregon, it struck me as a plant capable of improvement in its constitution (for it is not a vigorous plant), and even in the beauty of its flowers. I thought, if I could effect a cross between it and the scarcely less beautiful and much hardier *S. Elizabethæ* from the Tyrolean Alps, with its large rose-coloured and more compact flowers, I might in the hybrid effect an improvement on both parents. I accordingly set to work and was not disappointed in the result. The cross took, and from the hybridized seeds I succeeded in raising one plant, which partook more of the habit and aspect of the male parent, *S. Elizabethæ*. Of this hybrid I was very desirous to procure seeds, and to this fact I beg to direct attention: I found that with its own pollen it was sterile, yet while the male property was deficient, the female organ had all the appearance of being perfect. I then tried it with the pollen of *S. maritima*, and from this cross I obtained two finely-ripened seeds, which I have sown, but which have not yet vegetated. I tried a further cross on the same plant, with the pollen of the small *S. acaulis*, but though the seed-pods swelled, and promised seeds, none came to perfection. The experiment in its result is quite new to me, as I never before found the potency of the female to outlive the potency of the male organ.—I. ANDERSON-HENRY.

Durability of the Flowers of *Poinsettia pulcherrima plenissima*.—When a few weeks since I wrote of the possibility of having this splendid plant in bloom from November to May, Mr. Gilbert, of Burghley, asserted that I had been drawing on my imagination for my facts. The context of my note showed that I then anticipated such permanent flowering from a succession of plants, but it now appears as if one plant might flower the whole time from November to May. Our best plant flowered in October and faded in January—this was pretty well. Among several small cuttings one flowered in November, and is now (April 2) still in bloom, and looks as if it might go on to May. As regards colour I still adhere to the fact that *P. pulcherrima plenissima* is brighter than the single kind, but its habit of blooming for so many months in succession will probably prove a more valuable characteristic than that of heaping bracts upon bracts, which has earned for this valuable variety the name of *P. p. plenissima*. I am inclined to agree with another writer in THE GARDEN, who anticipates having *Poinsettias* all the year round by the aid of this last and best addition.—D. T. FISH.

Home Culture v. Imported Roots of Lily of the Valley.—My object in sending the Lily of the Valley spikes, to which you allude (see p. 246), was to show that fine roots of this favourite flower can be grown in England if nurserymen and others, having suitable ground for the purpose, would only take the matter in hand. Many tons' weight of clumps and bulbs of Lily of the Valley are imported every year, for which we have to pay foreign growers, besides a large sum for transit; surely, therefore, it is only consistent with common sense that the home culture of this flower should be as much as possible promoted. Nevertheless, the matter seems to be entirely overlooked, at least as far as any satisfactory result is concerned. The home culture of this Lily would, I feel sure, prove remunerative to growers, and therefore we ought not to send money abroad for what we can easily produce ourselves. I would strongly recommend some of our nurserymen to give the subject their serious consideration.—HENRY A. WOOD, Willow Lodge, Mitcham.

IVY AND ROCK SHRUBS ON THE MARGINS OF ARTIFICIAL WATER.

The planting of the banks near artificial water offers an opportunity for securing beautiful effects which cannot be too carefully studied. The contrast with the water, and the certainty that from across the water at least the result of tasteful planting will be seen (and not obscured by chance, or unrestrained growth, or unwise planting), should encourage the planter to devote his best attention to the subject. One of the happiest effects we have lately seen was afforded by Ivy on the rocky margin of well-formed artificial water, in combination with rock shrubs and hardy Cupressus and Junipers. Sheets of luxuriant Irish Ivy fell over the rocks and carpeted the banks. This, in pure air, is beautiful at all seasons, but especially so in winter, when it forms such a welcome contrast to the dismal dug surface on which so many of the beautiful shrubs in our gardens have to stand through most of the year. Among the evergreen rock shrubs and low Conifers suitable for such positions, a few good deciduous early-flowering shrubs may be placed with charming effect; such, for example, are the Japan Pyrus (*P. japonica*) and its varieties, the Forsythias, the large white Chinese Magnolia (*M. conspicua*), and other fine early-flowering kinds, and, in fact, any early-flowering showy shrubs. The attractive Chinese, Japanese, and Ghent Azaleas, and the Rhododendrons are, of course, admirable for such positions; but there is a peculiar fitness in placing the very early-flowering kinds on these well-carpeted green banks, where the surroundings are not so winterly as they are often, though needlessly, made in gardens.

TURFING LAWNS.

LAWNS are mostly worn through rather than worn out, and nothing looks worse than a patchy lawn. Such lawns are more common in small gardens than in large ones, and for this reason—that the smaller the lawn generally the more it is used. Grass, however, must be kept in good order, and wherever it is worn through the best remedy is fresh turf. How anyone with a small lawn can endure the operation of breaking it up, top-dressing, and sowing fresh seeds—as frequently recommended as a means of renovating old lawns and converting them into as good as new—passes comprehension. Why these processes cost more than the removal of the old turf and replacing it with new on the instant; and by doing this the lawn is sightly and serviceable at once. A score or two of tough new turves, 3 ft. long and 1 ft. wide, will often suffice. The entire worn piece should be taken up, and the new turves as far as possible placed in those particular spots where there is most wear and tear. Then all the best pieces of the worn turf can be cut or pulled out, and laid down afresh. If the turves be cut 1 in. or 1½ in. in thickness, they will hardly feel their removal, and will begin to grow and lay hold of the soil at once. Should the lawn be poor, the opportunity of removal should be embraced to place an inch or so of better soil under the turves. There is no better soil for this purpose than common kitchen garden earth that has been fairly cultivated for a series of years, and moderately manured.

And even should no better soil be available, a little fresh material should always be given on the removal of the turf in all cases where the Grass has not flourished. The soil gets Grass-sick, and a change of soil, if only an inch or so in depth, often puts quite a new face on worn-out lawns. But there are many lawns too rich as well as too poor, and what is more singular is, the rich lawns often wear through first. The Grass becomes rank and strong, and is easily broken down and worn through. The root fibres of the Grass never bind themselves into an impenetrable mass in such soils. Each blade has a root-stem merely, more like a tap-root than anything else, and there is a great want of root-fibre to knit the Grass into a tough, durable texture. The best means of renovating rich lawns is a change of surface and of turf. A layer of barren sand, 2 in. or 3 in. in thickness, under the turves, is a perfect cure for thin and easily worn through rich lawns. The turf forms a perfect network of roots as it grows over and through the sterile layer.

Many lawns are also ruined by meaningless inequalities of surface. Large lawns may rise and swell into bold elevations, and sink again into easy slopes, running into charming valleys,

like, in fact, the heavings of the ocean as it sinks to rest after a storm. But though not all level, lawns should all be even on the surface. All little erratic prominences should be knocked down and all equally unmeaning hollows filled up. This evenness gives beauty to the elevations and depressions of sloping lawns, and is even more essential to those that are level. The shaving off or filling up of those trifling inequalities not only adds immensely to the beauty of lawns, but likewise proves a capital means of renovating those that are worn out. The entire surface under the turf being moved by the levelling, the roots of the Grass find fresh soil, and the turf is improved in

Cascade and Ornamental Water Margin.

consequence. The mere removal of the turf and the loosening of the soil under it renovate the Grass in an extraordinary manner at times. This has been a favourable season for such undertakings. The amount of rain has rendered the surface of the lawn soft and the turf easy to raise with the spade. The moisture of the earth has caused the Grass to grow again at once, while the yielding nature of the wet soil has enabled the roller to do its work with tenfold its ordinary force and efficacy.

Of course, during these different processes of renovating lawns opportunities will readily present themselves for the removal of weeds. When the surface is off, and the roots of Plantains, Dandelions, and Crowfoots are revealed, they might quickly and safely be touched with vitriol, which would kill them outright. The crowns of the roots of these and other weeds can also easily be picked out when the turves are off the soil. Advantage should, in fact, always be taken of all means of renovating lawns to clear them of all foreign substances at the same time. Lawns infested by worms can also be readily cleared of them when the turf is off. A good soaking of ammoniacal liquor will kill them when the turf is off. If this, or any mineral oils, or other substances be employed to kill worms, it may be desirable to have the turf

off for some days afterwards, to allow the strength of the worm-killers to escape. It is also safe practice to point over the surface before relaying the turf. Very small lavas might be flooded when the turf is off. This would make an end of insect pests, such as ants, slugs, and worms for years afterwards. Poor lawns, again, that could not be top-dressed, could readily be flooded with house-sewage or other manure waters. This would in many cases be as good, and infinitely cheaper, than a top-dressing of soil or manure under the turf. Another good plan of renovating lawns and also of keeping down worms and small slugs is to sow the surface of the lawn thickly with lime, soot, or fresh tanner's bark. These kill or deter the worms, and the first two form a valuable manure for the Grass roots as well.

The best season for these operations is from November to January. They may be performed up to March 1, or even later, but the benefits decrease with the advent of the new year, and the risk of partial failure at least is greater. When done before Christmas, the Grass runs together again at once after the laying of the turf; but if too late, the divisions between the turves will be so imperfect that a strong drought in summer will open them, which is ruinous to the appearance and enjoyment of a lawn. No doubt, copious waterings will prevent such evils; but waterings cost money, and there is no reason why money should be thrown away upon Grass lawns, which would have been perfect had the work of renovation or renewal been done before the new year, instead of late in the spring.

D. T. FISH.

LILY BULBS.

"DUNEDIN" has made statements in THE GARDEN respecting the anatomy of Lily bulbs which are certainly new to me, and I suspect to every one else. It is impossible either to deny or accept his statements as facts, much less the inferences which he draws from them, until we see in freshly-prepared specimens the process which he calls the development of the seed-bud into the flowering bulb of the following season. "Dunedin" would, I think, hardly expect many Lily cultivators—and I suppose there are some hundreds interested in this beautiful group of flowers—to sacrifice some dozens of their favourites in pursuit of science; yet how else can his statements be tested? The position, I take it, is as follows:—"Dunedin" has advanced some entirely new views, and on the strength of them has, he believes, upset many preconceived ideas about Lily growth, and in his early remarks been particularly severe on the want of "perceptive powers" of the unfortunate author of "Notes on Lilies," who early in 1873 contributed what was then thought to be a creditable addition to the stock of knowledge on the subject already extant. By-the-by, "Dunedin" did not begin his experiments to "trace the progress of the seed-bud till October, 1873." Since then knowledge has advanced, and the question to which "Dunedin" now offers a solution was asked by the same author in your pages (Oct. 23, 1875)—"Do Lily bulbs make fresh growth every year as does the Crocus? I submit this question for future decision." "Dunedin" did not then reply. But, apart from personal considerations, we want to know—is "Dunedin" right or wrong in his present reply to my question? The onus of proof lies, it seems to me, on his shoulders, and I propose to him to prove it thus to the horticultural world. Let a series of preparations, sections of bulbs showing the seed-bud in its several incipient, semi-developed, and fully-developed stages (in fact, the life history of the "seed-bud,") be put up in spirit or some other antiseptic fluid that will keep the specimens in a fresh, undecomposed condition for months at least, by "Dunedin," or under his supervision, and labelled with clear descriptions, so as completely to illustrate the views advanced, and let these be exhibited before the Royal Horticultural Society and there explained by "Dunedin," and afterwards be on view for a time in London, or be presented to the Museum at Kew, so that all interested may have an opportunity during the summer of familiarising themselves with the appearances on which these new views are based. Typical bulbs from each of the various groups of *Isolirion*, *Eulirion*, *Martagon*, and *Auxilirion*, in their various stages of development, should be exhibited, as these groups materially differ in

their appearance, growth, and treatment, under cultivation. If "Dunedin" will do this, he will render a great service to science as well as to Lily cultivation.

Colchester.

THE AUTHOR OF "NOTES ON LILIES."

— I have little to add to what was stated at p. 183 concerning Lily bulbs, but as the editor of THE GARDEN has kindly allowed me to examine "Dunedin's" specimens referred to at p. 269, I have ventured to sketch those which most clearly show the gist of the matter, as far as respects the "seed-bud."

(a) Axillary or "seed"-bud of Lily bulb as seen in January. (b) The same as seen in March, showing increase of size.

It will be seen at a glance that it is nothing more than one of the axillary buds which exist at the base of each scale in nearly all Lily bulbs; albeit, all but one or two of them are generally latent, yet it is nothing uncommon for three or four to develop themselves, as has been acknowledged. If "Dunedin" likes to call the axillary or root-stock buds of his Lilies "seed-buds," I believe he has a right to do so privately, but in justice to myself and other readers of THE GARDEN he should either use the terms generally employed, or fully explain those that he may use which are not generally employed by physiologists—of these the "seed-bud" is one—since, as shown by "Dunedin" himself, it is applicable to any of the axillary or scale-buds, which naturally develop themselves without becoming detached from the root-stock of the old bulb, and these have long been known as offsets. On referring to p. 209, "Dunedin" asserts, that the "seed-bud" and the "leaf-bud" differ very much, particularly in this, that the leaf-bud propagates the individual as well as the species, while the "seed-bud" continues the species, but not necessarily the individual." This, as I take it, means that the leaf-buds of *L. bulbiferum splendens*, for example, will reproduce that variety exactly, but that the "seed-bud" of the same plant is not certain to do so? If this be really the meaning that the sentence and its context below are intended to convey, I must say it is a statement which any one who has raised Lilies from offsets would not accept without proof, inasmuch as it is directly opposed to all the known laws of vegetable physiology. If "Dunedin" will again refer to my note (see p. 188), he will find that I say we have reason to believe that "Lilies not only become larger in the bulb but also more weighty without the assistance of leaves." To this "Dunedin" replies, that "It is, of course, at the expense of the substance stored up in the scales of the old plant;" but surely "Dunedin" must see that additional weight cannot possibly be obtained by the young bulb from this source; it is a mathematical impossibility; and as roots without leaves can only be of use in absorbing moisture, I infer that the absorption of water pure and simple accounts for the additional weight. At p. 261 "Dunedin" again asserts that *Lilium candidum* is no more an evergreen than any other species, whereas the reverse of this is a well-known fact to every Lily grower, seeing that the plant bears green leaves nearly all the year. At p. 188 Mr. G. F. Wilson remarks that "the bulb of *L. giganteum* unmistakably dies after flowering;" but both Mr. Wilson and "Dunedin" (who quotes the sentence on p. 261.) omitted to mention that previous to the decay of the old bulbs, *L. giganteum* throws off young plants in the shape of offsets, the plant dying only in the sense that an American

Agave or a Pine-apple plant dies, that is, after having reproduced itself viviparously; indeed, if the bulbs of *L. giganteum* did "unmistakably die" in the absolute manner inferred by "Dunedin," what would become of his "seed-bud" theory in that case? No possible good can come of wrangling over terms in nomenclature, and now that I am enabled to give definite sketches of the "seed-buds" described by "Dunedin" (see p. 260), I shall submit the matter to the attention and judgment of those most interested in the subject. F. W. B.

THE SEA-SHORE NARCISSUS.

(*N. CALATHINUS*).

This delicate little plant, one of the rarest of all the species of Narcissus, has just bloomed in the garden belonging to the Naval Hospital at Brest, whence M. Blanchard has sent me fresh specimens in flower. This Narcissus is found in the north of the Isle Drénee, one of the Isles de Glenans, a group lying southward off the coast of Finistère in Brittany. A variety of *N. calathinus* is also found on the mountains of Gerez, near Amaranta and elsewhere in Portugal, whence Baron Pavia sent specimens to Kew. The conditions under which *N. calathinus* grows naturally in Brittany are very peculiar; it is found only in patches on short Grass which is constantly moistened with particles of sea water or spray, carried thither by winds. The climate is constantly mild (there being no frost), and the plant seems to delight in a soil consisting of heath-mould and sea-salt, and in a constantly moisture-laden atmosphere. It does not succeed in the comparatively dry air at Brest, where rain falls 180 days in the year; and as the late M. Thuret failed to cultivate it successfully in his garden at Antibes, one may infer that something else besides a genial temperature is essential to its welfare. This Narcissus has often been introduced to this country, but it has rarely if ever flowered. The only cultivator indeed who has succeeded with it is M. Blanchard, who grows it under the protection of a frame. It is distinct from the *N. triandrus* of

Narcissus calathinus.

the "Botanical Magazine," vol. ii., t. 48, the latter being a variable and much more vigorous plant from the Pyrenees. The structure of the flower is nearly the same in both species, except that *N. calathinus* has a longer and larger cup. A wider range of specimens might, however, show them to be but forms of the same type, notwithstanding a somewhat different geographical distribution. The annexed engraving shows the general habit of growth assumed by this species and a detached flower about one-fourth its natural size. The bulbs are about an inch long and half-an-inch in diameter, bearing from two to five bright green leaves, each about 1 ft. in length and rarely more than one-eighth of an inch broad; in section they are acutely lunate with a double keel. The flower stems are as long or longer than the leaves, smoothly cylindrical, and each bears one or two flowers which are 2 in. or 2½ in. in length, the ovary and flower tube, the petals, and the cup, being about equal, or rather more than an inch in length. The petals are of a delicate sulphur-yellow inclining to white, the tube being yellow and the cup almost pure white. The plant when well grown is most beautiful, and, notwith-

standing its peculiarities, it well merits careful culture at the hands of all lovers of choice, hardy flowers who may be fortunate enough to procure bulbs of it. In some favoured, spray-moistened spots near the coast in Devon or Cornwall, it might succeed if carefully planted; or imported bulbs might be grown in pots of their native earth sheltered by a frame from which frost is carefully excluded. B.

Anemone fulgens as a Market Flower.—Is not this beautiful, early-flowering Anemone worthy the attention of market growers, as it could be made to produce a large quantity of blooms in a small space, and probably might easily be quickened into flowering, if good-established clumps of the roots were lifted early in winter and placed close together on a bed of leaves, or spent tan, or any material that would afford a gentle warmth? With a frame placed over them and thus protected from heavy rains and frosts, no doubt the blooms could be produced considerably earlier than from the open ground. Even in the latter case a considerable breadth of the roots planted up beneath the shelter of trees would yield a large quantity of flowers early in spring.—A. D.

Lilium giganteum and other Lilies.—As some of my gardening friends foreboded all manner of evil to Lily bulbs from the continued rain of autumn and winter, and as the shoots of most Lilies are now aboveground to speak for themselves, will you allow me to say that in the gardens here they are more than usually strong and healthy, and that blank spots are few and far between. A friend tells me that in his garden in Norfolk the treatment of *Lilium giganteum* is different from what we are accustomed to give it, and that it is most successful. The bulbs are planted at the side of a rich Vine border, which has had a heavy dressing of horse and cow manure. I am trying a bulb which he brought me up with a good dose of manure against some planted near it which are under the usual treatment.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

Wild Gardening.—I have just been looking over the "Wild Garden," but cannot find any mention of the Wood Spurge. Observing it in our clay copses last spring as being a very distinct and showy plant, I transplanted a quantity of it into our ornamental covers on slopes near the rides, and I am now quite pleased with it; the reddish-claret-coloured, terminal shoots, stems, and green flowers are quite showy and effective. I planted large quantities of the common garden White Lily last year in groups about the woods, but I am sorry to find that slugs or snails are devouring them in some spots, particularly in Grassy places, but where there is plenty of peat or leaf-mould they are thriving beautifully, and not at all molested. Colchicums are just peeping through the Grass; I ought to have a good show of these in autumn, for I planted fifteen or sixteen bushel baskets full last autumn.—G. B.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Narcissus minor and minimus.—Those who possess rockwork or narrow shrubby borders should not overlook these two Daffodils when bulb-planting time comes round. The latter variety is now especially attractive at Mr. Ware's, at Tottenham, where it grows in large patches on rockwork, and flowers abundantly, almost close to the soil.—S.

Calceolaria alexicanalis—This is the best outdoor Calceolaria with which I am acquainted, as it is generally exempt from disease, and it will succeed where others fail. It grows about 18 in. high; its flowers are pale yellow, and it is very suitable for back rows in borders or centres of large beds. It remains in flower late in autumn, and as to its spring treatment we have already planted it out in its blooming quarters.—A NORTHERN GARDENER.

Cypripedium spectabile Indoors.—Several plants of this Lady's-slipper are now in bloom at Kew. They are grown in pans, each of which contains five or six shoots, and although not very floriferous, the blooms are large and much more delicate than those usually seen out-of-doors, some of them being nearly pure white. As a pot plant for flowering early in the spring this showy terrestrial Orchid well deserves attention.—S.

Yuccas on Ivy.—In winter and spring one of the most satisfactory combinations that can be formed is that of Yuccas on a carpet of healthy green Ivy. It matters not whether the Yuccas are closely and picturesquely grouped, or placed at intervals over the Ivy, the effect is excellent. It would be even more charming when the Yuccas were in flower and the Ivy bore its summer growth.

Saving Stock Seed.—I was informed the other day by a large grower of Stocks for market, and who has an excellent strain of both the White and Scarlet Intermediate kinds, that the way in which he kept his strain true was by saving seed of each colour in every alternate year, and in no case to save seed of different coloured kinds the same season. This grower alone has now no fewer than 10,000 plants of Intermediate Stocks in 4-in. pots waiting to be shifted into 6-in. ones, and brought into flower for market.—J. W. S.

A WEST LONDON MARKET GARDEN.

NOTWITHSTANDING the quantities of small Salads of every description imported from France and the Channel Islands to our markets at nearly all seasons of the year, there are a few market growers near London who have turned their attention to the culture of Salads under glass during winter and spring, and who can apparently compete successfully with Continental growers as regards price and quality of produce. Through the kindness of Mr. Elliot, of Hammersmith, one of the principal growers of small Salads, I was a short time ago permitted to see whence came the hundreds of punnets of Mustard and Cress and other Salading which may be found at the present time in Covent Garden market. A large portion of the grounds, which consist of several acres, is occupied by span-roofed and lean-to ranges of glasshouses, each from 150 ft. to 200 ft. in length, and, in addition to these, there are about twenty ranges of pits, each containing upwards of fifty sashes.

Pine growing was formerly a speciality at this place, but now that there is so little demand for English-grown Pines in our markets, they are only grown in small quantities. The glass-covered pits therefore that were previously employed for Pines are now devoted to the culture of Cucumbers and Melons during summer, and in winter they are used for the culture of small Salads, Lycopods, Lobelias, Scarlet Pelargoniums, &c. Mr. Elliot is now directing special attention to Grapes, Salads, and Mushrooms, all of which he grows admirably. The Vines are planted about 2 ft. apart, in outside borders which are heavily mulched with manure and otherwise carefully tended. There has lately been erected a house 150 ft. long, with a northern aspect, and planted with Black Alicante. The Vines have made wonderful progress considering the time during which they have been planted, their canes are well ripened, and it is expected that they will do equally well as those in houses having a southern or eastern aspect, which many cultivators contend is indispensable to the production of well-coloured Grapes. Black Hamburg, Gros Colman, and Alicante are the only varieties grown here; they are never forced, but are allowed to advance naturally, a little fire-heat being applied when it becomes necessary, to dispel damp or prevent the tender shoots from receiving a check by sudden changes in the weather, should such occur. The different varieties come into use in the order named, and the aim being to produce fruit only of the best quality, high prices and fair profits are accordingly realized. The Hamburgs are generally fit for sale in August; Gros Colman in September, October, and November; and the Alicante in December and January.

Whilst the Vines are at rest, Scarlet Pelargoniums, Mustard and Cress, Tarragon, &c., are grown under them. Scarlet Pelargoniums are, for the most part, grown in 5-in. pots, but large quantities of them are also in 8-in. and 9-in. pots in good rich soil; they are kept well pinched back, in order that they may form bushy specimens, well laden with bloom, for decorative purposes during the London season; such plants as these last for a long time in good condition, and, when associated with others, their brilliant scarlet blossoms have a fine effect. Mustard and Cress are grown on the floors of the houses, which are parted off into beds. Every other day a portion is cut and another sowing made, thereby keeping up a continuous succession. After sowing, the beds receive a good watering, and are then covered over with mats, which are immediately removed when the seeds commence to germinate. Mustard and Cress are usually cut when they have attained a height of 1½ in. or 2 in., a long-bladed knife with a crooked handle being used for the purpose. With this in one hand, the operator cuts as much as he can support with the other hand, and about as much as he thinks will fill a punnet; he then takes it up with both hands and places it in an upright position in the punnet, and so evenly do practised hands perform this work that one would almost think the Mustard and Cress had grown in the punnets instead of having been placed in them. During January, February, and March, Mustard and Cress are fairly remunerative; but after they can be obtained out-of-doors, they are almost valueless as market crops. The bright blue Lobelia speciosa is also largely grown here; it is struck from cuttings in autumn, potted into 6-in. pots, and during the winter and early spring it is placed

in lean-to pits close to the glass. To these air is freely admitted on every favourable occasion, and on mild sunny days the sashes are removed. In this way compact-flowering, marketable plants are got ready by May. Mignonette is also grown in pots for cutting during winter and for furnishing saleable plants in spring. Stocks, too, are grown extensively both in pots and in beds in frames; those grown in the latter being sold for planting out, and the former for window decoration. Mint, Tarragon, Borage, and Mushrooms form important crops. To the former are devoted five long ranges of pits, the contents of which are brought on in succession, and yield a supply of green Mint from January until it becomes plentiful out-of-doors; during severe winters, Mint realizes good prices, but in very mild ones it can often be gathered out-of-doors as soon as from the last pit. Tarragon is grown in large pots placed about the Vineries; Borage, for a winter supply, is produced in temporary wooden frames protected from the weather by means of mats, &c., this being succeeded by plants raised in heat in spring, and planted out as soon as the weather becomes sufficiently mild.

Lycopodiums (consisting chiefly of *L. denticulatum*) are grown in 6-in. pots in pits close to the glass. They are never shaded until sunshine becomes powerful, and more sturdy or evenly-grown plants it would be difficult elsewhere to find. Old plants are divided into small pieces, four or five of which are put into a 6-in. pot, previously well drained and filled with good, rich mould; they are then subjected to a moist, warm temperature, and as soon as they begin to cover the pot enough soil is added to form a mound on the top. The plants soon root into this fresh soil, and, as they become established, they are copiously watered and given abundance of air and light. The best are picked out every other day for market. Plants grown in the way described above last a much longer period in good condition than those which are grown in damp, sunless places, at a long distance from the glass. When the weather is sufficiently mild for Lycopods to grow in unheated pits they are at once removed to such positions, and the vacant pits are filled with hot manure and planted with Cucumbers or Melons. The heating apparatus here is by no means on modern principles, a saddle boiler being supplied to each range. Mr. Elliot remarks that in these boilers he can burn any kind of rough fuel, such as cinders and ashes obtained from London mansions, and they are therefore in this respect the most economical. The whole of the houses and pits here are strong, well-built, and kept well painted, and cleanliness and order prevail throughout the whole establishment. Mushrooms are grown in ridges out-of-doors, and the ground here lying high and dry excellent results are obtained, and even in the bad season Mr. Elliot has had enormous quantities of first-rate Mushrooms. The remaining ground is very heavily manured during the winter, and deeply dug or trenched to prepare it for Lettuces, Endive, and other Salad crops during the summer. S.

Clearing Greenhouse Plants of Insects.—At this season of the year aphid and thrips are apt to be very troublesome, and, from the fact that many greenhouses attached to villa residences are badly constructed, an effectual fumigation by means of Tobacco-smoke in the ordinary way becomes somewhat difficult. My own house is a case in point: the roof is so loosely constructed that the smoke passes away through the openings before the insect pests are destroyed. I am, therefore, led to adopt a plan of my own. Once a week I put some soft soap and flowers of sulphur into four gallons of soap-suds, mixing all well together. The next process is to turn the plants heels upwards and immerse their heads in the soapy solution; but before doing this I prepare a circular piece of stiff card with a hole ½ in. in diameter, and a slit reaching from the central opening to the circumference of the card. This is then stretched so as to allow the stem of the plant to be surrounded, and by pressing the fingers of the left hand firmly against it and to the rim of the pot when the plant is turned upside down, no soil can fall into the mixture. By gently moving the head of the plant backwards and forwards in the solution, the leaves become cleansed of insects, and as a kind of soapy gloss clings to the leaves after they are dry, insects do not quickly infest them again. This suggestion is principally intended for amateur cultivators who may be placed under circumstances similar to those to which I have referred.—D.

HARDY FLOWERS IN LONDON GARDENS.

AMONGST hardy flowers now in bloom Squills, Daffodils, and Hepaticas, still keep in the foremost rank; Dog's-tooth Violets are also now at their best, and amongst them the white-flowered form (*Erythronium Dens-canis album*) is especially attractive. Snowdrops and *Iris reticulata* still remain in great beauty, and the variously-coloured Persian *Iris* is likewise flowering freely. The White Squill (*Scilla bifolia alba*), now finely in blossom, contrasts well with the blue-coloured kinds, as does also *S.*

Corydalis cava.

bifolia rosea; *Puschkinia scilloides*, too, is yielding abundance of delicate, blue-striped, white flowers in Mr. Barr's grounds at Tooting, where may also be found *Sisyrinchium album* in good bloom, growing on well-drained, raised beds. *Primula denticulata* and *P. pulcherrima* are now flowering profusely in sheltered situations, but owing to the late heavy rains their flowers are not so bright as they would have been had the weather been more favourable; these Primroses under glass at Tottenham are, however, all that could be desired. The lavender-coloured form of *Muscari botryoides* (*M. pallida*) is now blooming abundantly in Mr. Parker's grounds at Tooting, where *Aubrietia purpurea grandiflora* is also a mass of cheerful-looking blossoms. For edgings or tufts on rock-

Silene pendula.

Viola cornuta.

work, or other raised positions, this variety of *Aubrietia* is invaluable. The Star Anemone (*A. stellata*) is now abundantly in flower in London nurseries, and the White Wood Lily (*Trillium grandiflorum*), growing in moist, sandy loam is opening its blossoms in large numbers. Two rare varieties of *Polyanthus* are now flowering freely at Mr. Parker's, one is *P. platypetala*, a variety with semi-double purple blossoms, and the other *P. Viceroy*, a yellow-eyed, richly coloured kind; in an unheated conservatory or greenhouse these *Polyanthuses* would prove extremely useful. The graceful though not particularly showy *Ornithogalum nutans* is flowering freely in several London gardens, and the early Forget-me-not (*Myosotis dissitiflora*) is becoming very beautiful; where it is grown in beds, it just now resembles little meadows of rosy buds and clear sky-blue flowers. S.

THE KITCHEN GARDEN.

PLANTING ASPARAGUS.

THOSE who are making plantations of Asparagus would do well to notice how that operation is conducted at Argenteuil (see p. 246). The worst way of growing it with which I am acquainted is in the old-fashioned beds, which devour annually as much stable manure as would suffice to dress five times their extent of surface in other parts of the kitchen garden, and usually with anything but a satisfactory result. I grow single plants in a single row with an interval of 30 in. from plant to plant. Grown in this manner, without a second row near them, they are able to extend their roots as far as they like on either side; and they may therefore be allowed to stand nearer each other in the row than those do at Argenteuil. I was induced to try this method three years ago, from having noticed for the last few years a single plant which had come up self-sown near the branches of an old espalier Apple tree. This plant has never been dressed with manure of any sort, and I have observed that what was cut from it was always finer than the average produce of the beds. I took the hint offered me by this intruder, and have profited by it. My single row produced largely last year, and now it has received for the first time a top-dressing of manure. Along one side of the row there runs a wide path, and on the other is an ordinary kitchen garden border, and all that we have to attend to is not to dig or crop too near the row. An occasional dressing of salt, or soot and salt mixed, and rarely one of stable litter, will probably be quite sufficient to maintain the plants in full vigour for several years; but by growing them on this system we can change our ground as often as we like, and plant in other parts of the garden new rows when we think it is time for any of the old ones to be uprooted and destroyed. There are probably few plants that require root-room more than does the Asparagus; hence the impropriety of crowding it in beds, where, owing to the seedlings which are continually being produced, it has often to struggle even for existence. I have just put in a row of Conover's plants, one-year-old, which were raised here from seed.

Wing Rectory, Uppingham.

B. S.

DWARF KIDNEY AND SCARLET RUNNER BEANS.

THE dwarf Kidney Bean is one of the most useful vegetables grown as an out-door crop, and it is also most accommodating if cultivated under glass. It is very impatient of cold, and therefore a warm sheltered situation should be chosen for it. Crops of it are often damaged by being sown too soon; the second week in May is a good time to sow the first crop, and a second sowing at the end of May will furnish a supply till Scarlet Runners come in, after which the Dwarf Beans are seldom asked for. The latter should have 2 ft. between the rows, and 10 in. in the row, and the tall growers 2 ft. 6 in. row from row, and 1 ft. apart in the row; they like a good, rich soil that has been well manured for a previous crop, which is better than rank manure, in which the plants are apt to run too much to foliage instead of fruitfulness. In very hot weather they enjoy a good damping over the foliage about five o'clock in the evening through a fine-rosed watering-pot or garden engine. Such treatment strengthens the plants and prolongs the gatherings; it also obviates attacks from red spider, to which they are liable. For the first sowing Williams' Early Prolific is an excellent cropper and comes in early, and Pale Dun is a good kind for a general crop, with Canadian Wonder for large pods. Runner Beans require similar treatment to the dwarf kinds, with the exception of the distance between the rows, which should be 4 ft. apart and 1 ft. in the row. They can be grown with sticks in the same way as Peas, pinching out the points when they reach the top, or they may be run up strings. They are a very valuable crop for both the amateur and the cottager. They do not take up much room, and they can be run on strings against boards or a building, on which the old Scarlet, which is one of the best for general cropping, has, when in flower, a fine appearance. Even in some of the most confined town gardens may often be seen Scarlet Runners flowering profusely and bearing pods in abundance. JAMES SMITH.

Waterdale.

Seashore Seakale.—From three stools (or heaps, as we call them) I have just cut a boxful of excellent Seakale blanched by merely covering it with the shingle where it grows wild. Some of it is very fine, but the high tides, which we had about the new year, damaged a great deal of it in a great many places along the shore.—W. WATSON, *Englehurst, Fawley, Hants.*

Preserving Vegetables.—I should feel very grateful if any of your readers who would kindly inform me how Peas and French Beans may be preserved in tins or otherwise for winter use.—H. GILBERT, *Burghley.*

THE FRUIT GARDEN.

INFLUENCE OF EARLY OR LATE PRUNING UPON THE TIME OF BLOOMING.

It is to be regretted that this subject appears likely to drop before anything further has been adduced in support or otherwise of the opinions held by Mr. Fish (p. 151). Amongst the immense number of hardy fruit growers throughout the country there must be many cultivators who have frequently in the same seasons pruned a portion of their trees early and others late, and who are sufficiently observant to have noticed the different effects (if any) caused thereby. There is nothing in the whole range of gardening in this country that is of greater importance than hardy fruit culture. A late season of blooming is a matter of the greatest importance in securing a crop, as the further the season is advanced when the blooms expand, the less likely they are to suffer through the effects of frost; and if the supposition were correct that the time of blooming was retarded by pruning late, no matter how inconvenient it might be to defer the work, still there could be no question as to the advisability of doing so. By my communication in reply to Mr. Fish (p. 183) it would be seen that what I have observed in my own experience is directly opposed to the theory of the time of pruning having any influence on the time of blooming of deciduous fruit trees, although I have met with those who held that it had, but I always found that such opinions were based upon mistaken and hasty conclusions. One individual with whom I discussed the subject was of opinion that because early pruning accelerated the time of blooming in such things as Roses and Honeysuckles, and plants of a similar nature, it must, as a necessary consequence, have a like influence upon the fruit trees in question; yet such is by no means the case, Roses and Honeysuckles, especially the former, in mild winters, commence growing almost with the advent of the new year. These and other plants of similar habit make a considerable amount of wood and leaf growth before the flower-buds are at all perceptible, totally different from the fruit trees in question, the fruit-buds of which are formed the autumn previous, and which make no wood growth previous to the development of the flower-buds, which is the first effort that the trees make in spring. Another argument I have heard advanced in support of early blooming resulting from early pruning, is that by pruning the branches are reduced, and consequently the quantity of fruit-buds which a tree carries (the root-power being concentrated in supporting the reduced number of buds) induces earlier growth. Yet there cannot be a greater mistake than this; any one who has taken the trouble to examine the roots of the trees in question at different times through the winter and spring would find that under ordinary circumstances no root extension takes place until some progress is made in leaf development, the roots during that time merely acting as channels to supply the amount of water required by the heads of the trees. The first efforts at growth occur in the fruit-buds themselves, and these are wholly influenced by the temperature of the air and the direct action of the sun's rays. Many years ago I recollect a couple of very large, old, standard Pear trees of the same variety standing close together in a severe storm during December, and four-fifths of the head were blown completely off one, leaving nothing but a few of the lower branches. A diligent observer in matters connected with fruit culture at the time made the observation, "Now we shall see whether the reduced quantity of fruit-buds the roots have to support will in any way influence the time of blooming, and the time of the fruit ripening, and to what extent the fruit will be larger." There was not the slightest perceptible difference in the time of flowering of the storm-shivered tree and the one beside it left unscathed; as might be supposed the fruit was double the size, and took longer to come to maturity, the increased size evidently causing this. If by a reduction in the number of fruit-buds the roots acted earlier upon them, on the springs succeeding wet sunless summers, when comparatively few fruit-buds have been formed, we should see the bloom expand correspondingly earlier and totally independent of the weather; or in the case of two trees of the same sort standing side by side, as is

frequently seen—one in a fruitful condition, thickly studded with blossom-buds, the other furnished with comparatively few—then we should have the latter blooming earlier than the former; yet whoever saw such to be the case? From long and careful observation on this subject I feel convinced that the influence on early blooming, by early pruning in the trees in question, only exists in the imagination of those who hold the opinion that early pruning has this influence. I also think that horticulture is the reverse of being either scientifically or practically benefited by the advancement of such theories as this, unless those who bring them forward are in a position to substantiate them by something stronger than the arguments at present adduced.

T. BAINES.

EXPERIMENTS IN MAKING VINE BORDERS.

ALLOW me to say in regard to Mr. Hunter's experiment with leaves and cow-manure as a compost for Vine borders, that it will be interesting to learn by-and-by how the Vines behave permanently in such a compost. I venture to predict that the ultimate result of Mr. Hunter's experience will be that he will keep to the loam as the best staple for Vine borders. So far, the fact of the Vines rooting so readily in the fresh leaves and manure is not in the least degree "startling;" on the contrary, I should have been surprised had they refused to do so. The value of the experiment, should Mr. Hunter continue it, will consist, as I have said, in proving whether or not the Vines will continue to thrive in such a compost. No fact in Vine culture has been more frequently demonstrated than that Vine roots run greedily into and riot wantonly in fresh leaves and manure. For this reason, gardeners dare not neglect the frequent turning of the fermenting material on their Vine borders, for the Vine roots would take possession of it at once, and it could not then be removed without sacrificing a great portion of new roots. Many years ago I left a thick lining of fresh leaves and litter containing a large portion of horse manure upon a Vine border all the season without turning it (as the Vinery was going to be taken down and rebuilt as soon as the crop was cut), and when it came to be removed it was so permeated with roots throughout, and held together so, that it might have been carried away bodily. But with such instances cultivators are familiar. In fact, Mr. Hunter's experiment is not the first of the kind that has been made. At p. 67 of his book on the Vine, Mr. Thomson relates how he made an inside border of "hot fermenting manure and leaves," how readily and abundantly the Vines rooted in it, how it improved the Vines for a year or two, how he added to the border with the same material as the old subsided, and how the "sentence at one time recorded against the Vines had been revoked" for the time being in consequence of the success attending the experiment; but the Vinery in question was done away with eventually, and I believe Mr. Thomson's experience of a manure and leaf compost for Vines was not of a kind to lead him to alter his opinions on the subject of Vine borders as recorded in his treatise on the Vine.

As regards the bricks and mortar system of building up Vine borders of whole turves, described by Mr. Hunter as being expeditious, and as it does not appear to be of much importance to the Vines one way or the other, I do not see why the plan should not be always adopted when turf is used. We have put several Vine borders together here exactly as Mr. Hunter describes, but it was to save time, and the mortar in our case was represented by ground bones and night soil previously deodorized with loam. We did not expect any special advantage from the plan, for when we do use artificially-prepared composts we thoroughly mix the materials together. Still I cannot say that there is any difference in the Vines in the borders of both kinds, and we have them side by side, that is, borders made up of layers of whole turves and manure alternately, and others of turf chopped and mixed with manure in the usual way. If we once admit that manure may be applied to Vines, and I think most growers admit that, then the only question is, How should it be applied? and I submit that the best plan is to mix it intimately with the soil or apply it in the form of top-dressings or in a liquid state. Of course I am speaking of borders that have not to be remade every five

years or so. Mr. Henderson, of Cole Orton, who must be classed amongst the few growers who have produced first-rate Grapes in a constant way for a long period of years without changing the Vines or the borders—a true test of good management—may be listened to by the general cultivator on the subject of borders. Writing to me a year or two ago regarding his Vines, he says:—"The only Vine borders I have made here were made of rather light loam, on the red sandstone formation, with the addition of one-twelfth of good stable-yard manure; no other materials were used, and the Vines planted in this have always borne the best Grapes; the borders were only made 7 ft. wide and 18 in. deep, and the Vines have been bearing for thirty-four years;" during which time I may add that Mr. Henderson has been one of the foremost prize-takers at our great shows. I have seen some of the latest exhibits by Mr. Henderson from these Vines, and though the bunches were not sensational as regards size, still they were fine, and in size of berry and finish I have rarely seen their equal. After all is said, however, about borders, they are a secondary consideration compared with the care of the branches. An escape for gross juices pumped up by the roots must be provided, and this escape—their safety valve—should consist of a good spread of foliage, as much as possible exposed to light and air. I have known poor, debilitated Vines restored to high health and vigour by simply giving them more room and light, without doing anything to the border beyond giving it the annual dressing and watering.

Wortley.

J. S.

Temperature of Vine Borders.—In structures where the front walls are of considerable depth of stone or brick, it is not uncommon to find the outside border much warmer, during the summer months, than the inside portion, which is shielded from the sun by the canopy of foliage; by testing the soil with a thermometer, correct conclusions can be easily arrived at. The outside border, in many respects, has advantages which cannot be provided for that which is shaded, and the latter is, of course, less assisted by Nature. The exposure of the soil to sun and air, the kindly rains of summer, and the border being less likely to suffer from injudicious manuring, by liquids or solids, than when confined inside, are considerations of primary importance. The warmth from the sun and the action of the air on the outside border may be some of the means used by Nature to draw the roots from under cover to the open-air border. Many of the most productive Vines from which Grapes have been cut for many years, and equal, if not superior, to the best which have been exhibited for a long period, are from outside borders, and from some districts, where the rainfall is greatest, having received protection in winter to retain the heat in the soil, the roots are as safe as when entirely under glass. The rain direct from the clouds and full action of sun and air on the soil appear to be the best treatment of the roots. In some large establishments Vine borders are seen outside entirely, but oftener inside, with means provided to let the roots grow out, and this question is likely to affect young beginners in Vine culture most, as experienced men will always be guided by what has answered their purpose best.—M. T.

Desse Tardive Peach.—This to my mind is the best late Peach in cultivation. It is not a new variety; were it so, its sterling merits would soon become better known. Every Peach-cultivator knows the excellent qualities and fine appearance of the Bellegarde and of the Royal George. Well, this Desse Tardive Peach, which is of French origin, is very similar in appearance to the Bellegarde, having the same shape, with a brighter colour, and with the same texture of flesh and the same excellent quality, but it comes into use some weeks later. It might, indeed, very appropriately be called a late Bellegarde. Now, a late Bellegarde is a great improvement—for open-wall culture especially—on the Barrington and Late Admirable, which ripen about the same time. These two latter are suitable enough, and very excellent for house culture, but when grown on the open wall they have an ugly greenish look about them; and it is only a certain proportion of them that are of average quality. They are coarse-grained at the best. There is a wonderful drop-down both in tone and quality, from the mid-season Peaches of the Bellegarde type to the late varieties as at present cultivated. This Desse Tardive will carry on the good appearance and the good quality to the end of the Peach season—till October. At Chiswick last season, according to "A. F. B.," in the "Florist," it fruited on the open wall, two small cordon trees producing eighteen fruits, which were gathered on September 30. They were all large and

highly coloured, and of most excellent quality. Here, therefore, is a speciality worthy of the attention of some of our enterprising nurserymen.

Fruit Crops in Worcestershire.—The fruit crops in this district—from which, on account of the extensive orchard cultivation of Apples and Pears, so much is expected—are very promising indeed. The change to the somewhat cold weather lately experienced seems to have done much to retard the opening of the blossoms which were unusually forward. Peaches, Nectarines, Plums, and Cherries promise an abundance of fruit if late frosts should not do any subsequent mischief. In private gardens, trees young and old are full of fruit-buds. Many trees here, both on walls and as standards, are looking well, and they were mostly planted as late as April and early in May last season. It is very evident that the orchard trees suffered from the superabundant crops they produced in 1875, when the fruit did not in many cases pay for the gathering. On younger dwarf-kept trees, where thinning was practicable, the results were different, as many fine fruits were harvested from them in capital condition. It is pleasing to observe that a change in hardy fruit culture is taking place, and that something which will give better remuneration than the old system of allowing valuable land to be wasted by being occupied with old, worn-out, neglected starvelings, is being substituted. Young trees are planted thickly and get early into bearing, and as they extend, thinning and transplanting are practised with good results.—M. TEMPLE.

Black Ants and Peach-flowers.—I, like "J. G." (see p. 250), have not observed ants to do any material injury to Azalea flowers, but they have always been a source of great annoyance to me here by the depredations which they commit on the blossoms in an early Peach-house. Every season, immediately a few blooms become expanded, they commence a most determined attack upon them, burrowing their way into the inside of the flowers, and never leaving them until the hearts are completely devoured. In order to keep them in check, so as to secure anything like a crop, an immense amount of trouble has been incurred in trapping, poisoning, &c.; but all the remedies which I have tried have only been partially successful until this season, when, quite by chance, I tried some of Scott's Wasp Destroyer, which has been productive of the most satisfactory results, for even after one application I found their numbers greatly reduced, and, after a second, there was not a living ant to be found in the house. I would therefore recommend any of your readers who may happen to be troubled with black ants to give the above mixture a trial.—JAMES WOODFIELD, *Osberton, Worksop.*

Inside and Outside Vine Borders.—As different opinions prevail amongst cultivators with regard to Vine borders, a comparison of notes may be useful. As to Vine roots leaving an inside border to go outside, I am of the same opinion as Mr. Hobday (see p. 210) that the cause is want of proper management; for early Vines, an inside border has an advantage over an outside one; it keeps the roots more uniform in temperature, and as the atmosphere of the house gradually rises, so must it warm the surface of the border, and with 2 in. or 3 in. of rich top-dressing every season, the roots are kept close to the surface, which they prefer to an outside border in the months of January, February, and March. I am not an advocate for the borders being either all inside or all outside; I consider it an advantage without any detriment to have them equally divided, for this reason: if either the inside or the outside border require renewing, each one can be done at separate times without the least injury to the crop; and this is of importance, particularly in the case of growers for market. The best time to renew the borders of early and mid-season Vines is as soon as the fruit is cut, while the Vines are in full foliage; and if the new borders be made up of green turf so much the better, as it forms a mild hotbed, which starts the roots off into growth in a few days, and they get well established, whilst the Vines are in full vigour. During the operation of lifting, it is well to keep the Vinery close and moist for a few days.—JAMES SMITH, *Waterdale.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Pitmaston Pear.—I find this Pear to be a most vigorous grower and one which does well on the Quince, or indeed on any stock; in fact, either on walls, pyramids, or espaliers, it is in my estimation the finest Pear in cultivation.—JOHN WILMOT, *Isleworth.*

Protecting Fruit Trees.—I notice in a contemporary that mats sown together are recommended for protecting Pear trees, and in another paper that straw neatly tied in string is recommended for the same purpose. The latter is light and airy, but the former is heavy and dark, and there can be no doubt that the straw makes the best protection.—R. GILBERT.

PLATE LXVIII.

HARDY CACTI.

(WITH A COLOURED FIGURE OF ECHINOCACTUS SIMPSONI).

Drawn by H. NOEL HUMPHREYS.

We but infrequently hear or see some record of reputed hardy Cacti, but on investigation it usually turns out that the species in question have undergone no real test of hardiness. The winter may have been mild, or the autumn relatively dry, or the conditions under which the plants existed out-of-doors were not such as to entitle them to the epithet "hardy." As a matter of fact, the number of hardy species of this family at present known is very small, and those cultivators who, without a sufficient trial, report certain plants as hardy, cause many people loss and disappointment. There is such a wealth of hardy plants at our disposition that we can well afford to dispense, in most cases, with half-hardy or delicate subjects. On the other hand, there are certain types, such as the Palm, Cactus, Agave, Tree Fern, and others, so distinct in character and yet for the greater part too exacting as regards climatal conditions for the open air in this country, that it is worth some trouble and expense to ascertain which are the hardiest of these types. Further, there is one important point to bear in mind, and this is, a plant may be perfectly hardy in the south-west and along the western coast of the United Kingdom, and yet not sufficiently hardy to withstand an ordinary winter in the climate of the central and eastern parts, even in the latitude of London. Again, it is a matter for consideration what factor of our climate acts injuriously on the constitution of a given plant—whether the cold be too intense, the humidity too great, or whether the amount of light and heat be insufficient for its proper development. As regards the Cacti, there is no doubt that many species otherwise hardy succumb to the superabundant moisture with which the atmosphere is usually charged. With the exception of the genus *Rhipsalis*, all the members of this curious tribe are natives of America, extending from Chili in the south to Canada (up to 50° N. lat.) in the north, and finding their greatest concentration in Mexico, where many of the smaller species of *Mammillaria* clothe the mountain rocks as Lichens do in other countries. Probably none of the Mexican species, even those growing between an altitude of 10,000 ft. to 15,000 ft. above the level of the sea, would succeed in the open air all the year round in this country. The Chilian species have, so far as I know, not been tried, consequently at present we have only a few of the northern outliers which may be termed hardy representatives of the family, and these should be planted on rockwork in open, airy situations, where they are free from dripping water, and where the drainage is perfect. The following are hardy in all except the coldest and wettest parts of the kingdom:—

Echinocactus Simpsoni.—This has a greater outward resemblance to the genus *Mammillaria* than the one to which, from the structure of its flowers, it really belongs. According to Dr. Engelmann, the principal authority in all that concerns the North American Cactea, this is the most northern species of the genus, and grows at a greater altitude than any of those out of Mexico. He himself met with it abundantly in Colorado at an elevation of 8500 ft., and in South Colorado it grows at even greater elevations. The variety here alluded to was discovered on the gravelly moraines of the glacial period of Clear Creek Valley, between 8000 ft. and 9000 ft. altitude, and in the southern part of the territory, the Sangre de Cristo Pass at 10,000 ft. high. In its native habitat it enjoys a dry climate, and it is, in some seasons at least, more or less protected from the effects of frost by a covering of snow. But in this country it has withstood 32° of frost without injury, and therefore, if proper precautions be taken with regard to limiting the amount of moisture, both overhead and at the root to the lowest quantity possible, it may be called perfectly hardy. Messrs. Backhouse & Son, of York, introduced living plants of it through their collector a few years ago, and both they and Dr. Engelmann agree in describing the flowers as being more of a pale purple tint, and of a more regularly circular outline than represented in the accompanying figure. It should be mentioned that this is a reduced portrait of the plant, which, in a wild state when fully grown, is 3 in. to 5 in. high, and 3 in. or 4 in. in diameter. But as an exact description will be useful to amateurs, to enable them to satisfy themselves that they have the right species, a transcription of some parts of Dr. Engelmann's description may

be given. In colour this species is of a dark green, and it has loosely-arranged tubercles. These are $\frac{1}{2}$ in. to $\frac{3}{4}$ in. long, somewhat quadrangular at the base, about $\frac{1}{2}$ in. wide at the vertical, and $\frac{1}{2}$ in. in the transverse diameter, sub-cylindrical upwards; areola $\frac{1}{2}$ in. to $\frac{3}{4}$ in. long, and a little more than half as wide. The fruit-bearing tubercles are rather shorter and stouter. Outer spines $\frac{1}{2}$ in. to $\frac{3}{4}$ in. long, whitish, inner spreading stouter, and a little longer, yellowish and deep brown or black in the upper part; there is no truly central spine. In the very young plant the spines number eighteen or twenty, and are only from one-twelfth to one-tenth of an inch long. They all radiate and closely fit together with their compressed, bulbous bases on a linear areola, resembling in shape and arrangement those of *Cereus caespitosus*. Soon the areola widens, and six or eight short, stout, brown, interior spines make their appearance and diverge like the first. The development of the plant is exceedingly interesting. In early spring the young tubercles on the vertex of the plant begin to form, exhibiting their densely woolly tops, and soon afterwards, long before any spines make their appearance, the tips of the smooth, brown flower-buds come out. The flowers are about $\frac{3}{4}$ in. long, and of nearly the same diameter, externally greenish-purple; petals yellowish-green or verging to pale purple. The short stamens arise from the whole surface of the tube, leaving only a very small, nectariferous space in its face. The fruit is about $\frac{1}{2}$ in. long, and almost as wide, borne on a very large, circular areola, surrounded by a woolly margin. It bears towards the top one to three scales, sometimes with one or two small spines in their axils. The variety alluded to above was 1 in. in diameter in the smallest specimens, with every gradation up to the size of the type, and the spines more or less curved. This plant was named after Captain Simpson, the commander of an expedition to Utah, in the botany of which there are two plates devoted to it. This can scarcely be the species alluded to in the "American Gardeners' Monthly" in 1871, which it was stated grew on the Sierra Nevada of California, close to the snow, and attained the dimensions of a large Cabbage. It had been used as a vegetable, after paring, in lieu of Asparagus; and the plant was described as truly beautiful, round as a globe, and covered with snow-white spines. Probably this may all be attributed to the possible fact of the expedition party having tried it in the absence of a more toothsome vegetable; and the descriptive part may be regarded as purely imaginary. Be this as it may, our plant will be welcomed by all amateurs of the curiosities of the vegetable world. In some of the Belgian periodicals it was stated a few years ago that *Echinocactus viridiflorus* and *E. phoeniceus* were hardy at Ghent.

The next, and perhaps only other, genus of Cactaceæ furnishing hardy species is *Opuntia*. It comprises about 150 species, ranging from the southern limit of Cactus life in Chili to the northern limit in North America; one or two of the species have long been naturalized in the countries bordering the Mediterranean sea, and later in India. Indeed, in some of the early books on gardening and botany *O. vulgaris* is stated to be a native of Europe and North America. Little is yet known respecting the species native of the temperate regions of north-west America, but those found in the northern United States are three in number, namely:—*O. vulgaris*, *O. Rafinesquii*, and *O. missouriensis*. These have all large flat-jointed branches, minute scale-like leaves, and large showy yellow flowers.

O. vulgaris.—This species was cultivated in this country by Gerarde nearly three centuries ago, and was then so completely naturalized in the south of Europe that it was regarded as indigenous, and possibly after all it may be so, for many other genera (as *Platanus*, *Liquidambar*, &c.) are represented in these two distant regions by closely allied species. Philip Miller, one of the fathers of gardening in England, says:—"I have planted it under a warm wall, in a very dry soil, where it has continued for five years, and endured the severest of our cold without any cover, and has produced a greater quantity of flowers and fruit than those which were housed; so that the cold is not so great an enemy to this plant as wet, which, if suffered to lie long upon it, or given in too large quantities to the root, will destroy it in a short time." Some writers have confused this and the next, though Engelmann discriminates them as species, and Dr. Asa Gray retains them in his flora of the Northern States. This has pale green, flat, obovate joints, minute ovate or subulate closely appressed leaves, sulphur-yellow flowers, and a nearly smooth, pulpy, eatable berry. It grows on dry rocks and in sandy places, chiefly near the sea-coast, from Nantucket, Massachusetts, southwards.

O. Rafinesquii.—This was introduced into European gardens by Messrs. Haage and Schmidt in 1869. It differs from the preceding in its deep green joints (branches), larger flowers, which often have a red centre, more numerous (ten to twelve) petals, and the longer spreading, not oppressed leaves, from the axils of some of which proceed a few small spines and a single strong one $\frac{3}{4}$ in. to 1 in.

AN ALPINE CACTUS - ECHINOCACTUS SIMPSONI

long. Further, it is a native of the inland States from Wisconsin to Kentucky. At the present moment I have not the means of ascertaining whether the plant cultivated under this name is the true plant, nor am I able either to affirm or deny the statement that this is much harder than *O. vulgaris*. Doubtless in its northern habitats in Wisconsin it braves a more rigorous winter than its congener on the coast, but the latter must surely be hardy under proper treatment.

O. missouriensis.—Inhabiting the same region as *O. Rafinesquii*, from which it differs in its tuberculate branches, in its sinuate leaves, the axils of which are armed with a tuft of straw-colored bristles, and five to ten slender, radiating spines, and in its dry, prickly berry. This does not appear to be in cultivation in this country.

Among other reputed hardy Cacti are *Opuntia bicolor*, distinguished by its long spines and long, white hairs; *Mammillaria simplex*, *M. coronaria*, *Echinopsis Eyresi*, *E. falcata*, &c.: but these cases are not sufficiently authenticated to be acted upon without further trial. But independently of these we have in the plant figured here and the genus *Opuntia* two very distinct, hardy types of the Cactus family. Probably some readers of THE GARDEN may be able to furnish some information respecting the hardness of others. W. B. HEMSLEY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Cucumbers sown some time back and grown on in good-sized pots must at once be planted out in the frames in which they are to complete their growth. In turning them out of the pots be careful not to break the balls or disturb the roots in any way, or their progress will be checked. See that the soil in which they are planted is not too hot; they will bear a bottom-heat of 85° or 90°, but if higher than this draw the soil away all round from the hills in which they are planted, leaving these for a time no larger than will well cover the roots; the heat will shortly decline, and the soil thus removed can be replaced. Keep a small pot of water standing inside the frame so that it will get warm and fit for use.

Box Edging.—The principal objections to Box edging are that it affords a harbour for slugs and renders it difficult to apply salt to the walks for the destruction of weeds, or to apply it as a manurial dressing to the ground which the Box encloses; but apart from this there is no edging that equals Box in appearance when well kept. With amateurs it is frequently allowed to become too large through inattention to cutting, or by permitting it to remain too long without replanting. The present is a good time for either replanting or making up any deficiencies that may exist through the Box having died in places; the latter mishap generally occurs where the land is of a heavy, wet, retentive nature, and insufficiently drained, or it is killed through vegetable crops being planted too near it. If the haulms of Potatoes overhang it during the summer, or if Cabbages, Beet, or anything of similar character be too close, it gets killed. Where any considerable portion of the Box is dead it is much better to take up the whole and replant, as where the dead portions are simply replaced it has a patchy look. A Box edging that is well planted in a workmanlike manner, and one in which the operation is indifferently performed, produce as great a difference in effect as that resulting from good and inferior work in any gardening operation. As many amateurs may not have had any experience in Box planting, a few hints may be of use. In the case of existing edgings in the usual position, viz., bounding gravel walks that require to be thus treated, the first thing is to remove all the gravel from the sides, placing it in a ridge in the middle of the walk; take up the whole of the Box which should be heeled in to prevent the roots drying until the ground is prepared; commence at one end and dig where the Box has stood and is to be replanted about 1½ ft. or 2 ft. in width, breaking the soil fine as the work proceeds, leaving the top quite level or with a gradual rise according to the more or less sloping position of the ground. Care must be taken to have the surface thus dug of the right height proportionate to the ground which the edging is to enclose; if too high, it will have an awkward appearance, and if too low, it gets smothered through the rains washing the soil down upon it: this condition as to the requisite height is after it has been made solid by treading and beating with the back of the spade. Draw the line from end to end, quite straight or gradually curved as the course of the walks requires, with a spade open a trench cutting straight down so as to have it perpendicular on the off side, drawing the soil inwards; this trench should be the full depth of the spade, then commence with the Box, dividing it by hand, it will split up

readily, and care must be used to secure a portion of roots to all that has to be planted; begin planting it in a thin continuous line with the tops about 2½ in. or 3 in. above the surface, filling in the trench as the work proceeds with the soil that was taken out to form it, treading it with the feet solid so as to make it lie quite close. After the planting on both sides of the walk is done, replace the gravel, adding more if required; a little practice will enable the operator to plant the Box in a continuous, even line, all equal in height and breadth. All the subsequent attention necessary for some time will be in the matter of watering the Box in May or June if the weather be very dry.

Ivy on walls, covering arbours, or any similar structures should now be cut. This most useful of all plants for wall covering is very often neglected, and allowed to grow from year to year until the accumulated weight of the shoots not actually attached to the wall is such that, with the force of the wind, the whole gets torn away, in which case there is very great difficulty afterwards in getting it to attach itself properly to the wall, which often necessitates the complete cutting away of the loosened portion, and until the denuded part of the wall gets clothed with fresh growth it has an unsightly appearance. Another advantage in yearly cutting Ivy is that the leaves, which annually decay and fall off, are all cleared away at once, and although the Ivy thus stripped of its leaves for a few weeks looks bare, still, when the work is done at this season just as growth is about to commence, it shortly becomes clothed with new foliage of the most beautiful green. The present is a good time for planting Ivy; it is sometimes thought that this most accommodating plant (which will grow in some way almost anywhere except in situations where the soil is excessively wet) does not need the ground to be prepared for its reception, yet there is no plant that better repays liberal treatment, with good soil and plenty of manure. If the soil be deficient add as much as will bring it up to 1 ft. in depth at least, to which dig in 1 in. of good rotten manure; with suitable preparation Ivy will make more growth in a single season than it would in three seasons in poor, shallow soil. Where the space to be covered is limited in extent, I should recommend the use of plants that have been grown in pots, as those taken up from the open ground do not make nearly the progress the first season that those that have been kept in pots do; in which condition they are to be had in most nurseries often 6 ft. or 8 ft. in height, with several shoots each. Plants of this description at once cover a considerable surface; when turned out of the pots disentangle the roots without breaking them more than is unavoidable, spread them out and cover with 3 in. or 4 in. of soil, treading it firm, at once nailing the shoots into the position required. If the situation be inclined to be dry, as it often is near walls, mulch the surface during the summer with 3 in. of rotten manure.

Evergreen Hedges.—Holly, Yew, or other evergreen hedges should now receive what cutting or trimming they require. It is not well to cut hedges of this description in the winter, like those that are deciduous, for, should severe frost follow, the shoots are sometimes killed back considerably from the point where cut, whereas if the operation be performed now, danger from this cause is avoided. To equalize the strength and keep the bottom thick and close, leave them much wider at the base, sloping gradually upwards, having the top quite narrow to a point, as in the case of deciduous hedges. The old fashion of square-topped hedges of this description should never be followed. Where Yew hedges exist, they ought to be allowed to grow much wider and higher than Holly, as the plant, being naturally of large growth, will not continue in health if not permitted to attain a considerable size. Where a hedge has been planted merely for a screen or to afford shelter, it is not advisable to resort to formal clipping, as the desired end can be attained with much better appearance by simply shortening with the knife any branches that are outgrowing the rest.

Roses.—The remaining portion of these should now be pruned, as, if this operation be longer deferred, it will cause the bloom to be late; the dormant buds that have yet to start into growth will after this time not get so forward as to endanger their suffering by frost.

Shrubberies.—The practice of clipping evergreen shrubs, (such as Portugal or common Laurels), which was once so general, is anything but desirable, except in the case of plants that are encroaching upon walks, roads, or each other, and which cannot well be moved altogether from their position; but, in cutting these, do not use the shears or knife so as to leave an even surface; with a little judgment an irregular outline may be preserved, at the same time keeping them within the necessary bounds. Look over all specimens in the shrubbery to see that they do not nudely encroach on each other, taking up such as are of the least importance; for, although I prefer the end of summer for transplanting Evergreens, still it is better to move now—though it may necessitate a deal of labour in

watering through the spring and summer—than to allow valuable plants to injure each other.

Kitchen Garden.—Potato planting should be completed as soon as possible after this time in all places where the soil is sufficiently dry; but, although it is well to get this work finished by the middle of the month, where the land is wet and sticky, it is better to defer it even a fortnight later than to tread the ground whilst it is in this state. On seasons such as the present, when the land is wet, it is better to plant in holes made by the old-fashioned stick with a foot-rest than in drills made with the spade, as by the former means the ground is not nearly so much trampled on, and if boards be used to step upon, these can be made to do duty in place of a line; the holes can be filled in with the rake as the work goes on.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

April 9.—Potting Achimenes in 6-in. pots, putting sixteen plants in each pot. Potting spring-struck Centaureas, Nasturtiums, Veronica Andersoni variegata, Cedronella cana, Lobelia Paxtoni, various Petunias, and Viola cornuta. Shifting Caladiums, Tuberoses, Azaleas, Cytisus, and Camellias into larger pots; also Pot Vines. Sowing Asparagus. Planting two rows of Globe Artichokes, and second pit of Melons. Pricking off Marigolds, Prince's Feather, Love-lies-bleeding, Incomparable and Nine-o'clock Celery, and one light of second-sown Cauliflower plants. Tying up late Vines. Thinning fruit in Peach-houses where too thickly set. Sowing Asparagus beds. Clearing manure from Rhubarb crowns out-of-doors. Turling blank places in lawn. Digging land for Spinach, and cleaning Herb beds. Putting rimmed saucers under Strawberry plants, swelling their fruit, and staking Sweet Peas in open ground. Hoeing between vegetable crops, and taking litter off Vinery borders. Putting Seakale seed in water to soak, in order to hasten germination.

April 10.—Potting Tree Mignonette, using half loam, half cow manure, and some silver sand, and giving but a small shift at a time. Sowing Cattell's Crimson Beet; also Altringham and Long Orange Carrots, Champion of England and Victoria Marrow Peas, Long-pod Beans, Early Stone and White Dutch Turnips, Red and White Celery, Seakale, Sorrel, and Green-fleshed Melons, and a row of Sweet Peas. Planting Strawberries and Larkspurs. Pricking out Tagetes signata and Lettuce plants. Spawning Mushroom bed. Getting all established bedding plants out-of-doors. Thinning earliest-sown Turnips. Earthing up Cauliflowers. Clearing away Winter Greens that are running to seed. Cutting off all bunches of Grapes except one to a shoot from Muscat and Hamburgh Vines.

April 11.—Potting Fiferfew, Pentstemons, Hydrangeas, Balsams, and seedling Cyclamens. Shaking out and repotting scented Pelargoniums. Shifting Cissus discolor and putting it in heat; standard Chrysanthemums into 8-in. pots; and Fuchsias into 6-in. pots. Sowing French Beans under the protection of a wall; sowing also Cabbage, Winter Greens, Lettuce, and Veitch's Antenn Giant, Early London, and Walcheren Cauliflower, Cooling's Matchless and Melville's Broccoli, Sweet Basil, Marjoram, Australian and American Cress. Planting Beet for seed, and a good breadth of Asparagus. Pricking off Asters, Picotees, Carnations, Wigandias, Salvia argentea, and Zinnias. Sticking Peas. Tying up more Lettuce. Putting Broccoli fit for use into cellars in order to prolong its season as much as possible. Salting Cabbage ground. Sulphuring hot-water pipes in Fig and Strawberry-house to keep off red spider. Putting annuals from Vineries in sheltered spots out-of-doors. Covering Asparagus heads with soil where shoots are peeping. Watering Vine border. Earthing up Cucumbers. Hoeing among Strawberry plants. Manuring Rose trees and washing leaves in Hamburgh-honse to kill thrips.

April 12.—Potting Daturas in flowering pots and Sweet Peas in 12-in. ones. Sowing Radishes, Malope grandiflora, Spinach, Vegetable Marrows, and Ice plants; also Cucumbers, Melons, and Gherkins; likewise Scotch and Buda Kales. Transplanting earliest Celery into manure. Pricking out Arabis. Disbudding Peach trees in houses. Putting into cold frames recently pricked-off Lettuce and Cauliflower plants. Thinning Grapes and washing Cattleys.

April 13.—Potting blue Salvias, spring-struck Verbenas, Iresines, and young Tree Carnations. Shifting pot Vines into fruiting pots and potting off Cockscobs. Sowing French Beans and Grass seeds. Planting out all frame Violets. Pricking off Perilla and Stocks.

Putting in cuttings of Mrs. Pollock, Goldfinch, and Cloth of Gold Pelargoniums, and placing them in heat; also Plumbago, Bouvardias, and scented Verbenas. Watering under pipes in Peach-houses; earthing up last frame of Potatoes. Throwing out trenches for main crop of Celery. Digging Willow beds near pond. Raising temperature of Vines in bloom to 65° by night.

April 14.—Potting Wigandias and other fine-leaved plants for conservatory; potting off Balsams and seedling Lobelias. Sowing ornamental Grasses and Gourds, Incomparable and London Colewort, Fearnought Cabbage, Couve Tronchuda, and Seakale. Planting Lettuce and pricking off annuals in frames. Washing Gardenias to free them from scale. Covering Potatoes peeping aboveground with fine soil. Watering Cauliflower plants under hand-lights with sewage. Getting all established bedding plants out-of-doors; also Balm. Plants in flower in houses;—Lily of the Valley, Cinerarias, Azaleas, Aphelexis, Dentzias, Heaths, Oranges, Camellias, Cytisus, Rhododendrons, Tropaeolums, Mignonette, Violets, Fuchsias, Heliotropes, Ixias, Clematis Jackmanni, Crinum amabile, Passiflora princeps, Roses, Salvia splendens, Lilacs, Begonias, Mimulus, Genetyllis tulipifera, Hemerocallis, and Gesneras.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 250.)

Broom.

- (1) *Iris*. And thy Broomed groves.
Whose shadow the dismissed bachelor loves.
Tempest, act iv., sc. 1.
- (2) *Puck*. I'm sent with Broom before
To sweep the dust behind the door.
Midsummer Night's Dream, act v., sc. 2.
- (3) *Moa*. I made good my place; at length they came to the Broomstaff
with me.
Henry VIII., act v., sc. 3.

THE BROOM was one of the most popular plants of the Middle Ages. Its modern Latin name is *Cytisus scoparius*, but under its then Latin name of *Planta geuista* it gave its name to the Plantagenet family, either in the time of Henry II. as generally reported, or probably still earlier. As the favourite badge of the family, it appears on their monuments and portraits, and was embroidered on their clothes, and imitated in their jewels. Nor was it only in England that the plant was held in such high favour; it was the special flower of the Scotch, and it was highly esteemed in many countries on the Continent, especially in Brittany. Yet, in spite of all this, there are only these three notices of the plant in Shakespeare, and of those three, two (2 and 3) refer to its uses when dead; and the third (1), though it speaks of it as living, yet has nothing to say of the remarkable beauties of this favourite British flower. Yet it has great beauties which cannot easily be overlooked. Its large, yellow flowers, its graceful habit of growth, and its fragrance at once arrest the attention of the most careless observer of Nature. We are almost driven to the conclusion that Shakespeare could not have had much real acquaintance with the Broom, or he would not have sent his "dismissed bachelor" to "Broomed groves." I should very much doubt that the Broom could ever attain to the dimensions of a grove, though Steevens has a note on the passage that "near Gamlingay, in Cambridgeshire, it grows high enough to conceal the tallest cattle as they pass through it; and in places where it is cultivated still higher." Chaucer speaks of the Broom in somewhat the same way, but does not make it so much of a tree:—

"Amid the Broom he basked in the sun."

As a garden plant it is perhaps seen to best advantage when mixed with other shrubs, as when grown quite by itself it often has an untidy look. There is a pure white variety which is very beautiful, but it is very liable to flower so abundantly as to flower itself to death. There are a few other sorts, but none more beautiful than the British.

Burs.

- (1) *Celia*. They are but Burs, cousin, thrown upon thee in holiday
foolery. If we walk not in the trodden paths our very petticoats
will catch them.
Rosalind. I could shake off my coat—these Burs are in my heart.
As You Like It, act i., sc. 3.

- (2) *Lucio.* Nay, friar, I am a kind of Bur, I shall stick.
Measure for Measure, act iv., sc. 3.
- (3) *Lysander.* Hang off, thou cat, thou Bur.
Midsummer Night's Dream, act iii., sc. 2.
- (4) *Pandarus.* They are Burs, I can tell you—they will stick where they are thrown.
Troilus and Cressida, act iii., sc. 2.
- (5) *Burgundy.* And nothing teems
 But hateful Docks, rough Thistles, Kceksies, Burs.
Henry V., act v., sc. 2.

The Bur is the unopened flower of the Burdock (*Arctium Lappa*). Its clinging quality arises from the bracts of the involucre being long and stiff, and with hooked tips which attach themselves to every passing object. The Burdock is a very handsome plant when seen in its native habitat by the side of a brook, its broad leaves being most picturesque, but it is not a plant to introduce into a garden. There is another tribe of plants, however, which are sufficiently ornamental to merit a place in the garden, and whose Burs are even more clinging than those of the Burdock. These are the Acanas; they are mostly natives of America and New Zealand, and some of them (especially *A. sarmentosa* and *A. microphylla*) form excellent carpet plants, but their points being furnished with double hooks, like a double-barbed arrow, they have double powers of clinging.

Burnet.

Burgundy. The even mead that erst brought sweetly forth
 The freckled Cowslip, Burnet, and Sweet Clover.
Henry V., act v., sc. 2.

The Burnet (*Poterium Sanguisorba*) is a native plant of no great beauty or horticultural interest, but it was valued as a good salad plant, the leaves tasting of Cucumber, and Lord Bacon (contemporary with Shakespeare) seems to have been especially fond of it. He says ("Essay of Gardens") :—"Those which perfume the air most delightfully, not passed by as the rest, but being trodden upon and crushed, are three, that is, Burnet, Wild Thyme, and Water Mints, therefore you are to set whole alleys of them, to have the pleasure when you walk or tread." It also was, and still is valued as a forage plant that will grow and keep fresh all the winter in dry, barren pastures, thus often giving food for sheep when other food was scarce. It has occasionally been cultivated, but the result has not been very satisfactory, except on very poor land, though, according to the Woburn experiments, as reported by Sinclair, it contains a larger amount of nutritive matter in the spring than most of the Grasses. It has brown flowers, from which it is supposed to derive its name (Brunetto).

Cabbage.

Evans. *Pauca verba*, Sir John, good worts.
Falstaff. Good worts! good Cabbage.
Merry Wives, act i., se. 1.

The Cabbage of Shakespeare's time was essentially the same as ours, and from the cotemporary accounts it seems that the sorts cultivated were as good and as numerous as they are now. The cultivated Cabbage is the same specifically as the wild Cabbage of our sea-shores (*Brassica oleracea*) improved by cultivation. Within the last few years the Cabbage has been brought from the kitchen Garden into the flower garden, on account of the beautiful variegation of its leaves. This, however, is no novelty, for Parkinson said of the many sorts of Cabbage in his day: "There is greater diversity in the form and colour of the leaves of this plant than there is in any other that I know groweth on the ground. . . . Many of them being of no use with us for the table, but for delight to behold the wonderful variety of the works of God herein."

Camomile.

Falstaff. Though the Camomile the more it is trodden on the faster it grows, yet youth the more it is wasted the sooner it wears.
1st Henry IV., act ii., sc. 4.

The low-growing Camomile, the emblem of the sweetness of humility, has the lofty names of Camomile (*Chamamelum*, i.e., Apple of the Earth) and *Anthemis nobilis*. Its fine, aromatic scent and bitter flavour suggested that it must be possessed

of much medicinal virtue, while its low growth made it suitable for planting on the edges of flower-beds and in paths, its scent being brought out as it was walked upon. As a garden flower it is now little used, though its bright starry flower and fine scent might recommend it; but it is still to be found in herb gardens, and is still, though not so much as formerly, used as a medicine.

Carduus (see Holy Thistle).

Carnations.

Perdita. The fairest flowers of the season
 Are our Carnations and streaked Gillyflowers,
 Which some call Nature's bastards.
Winter's Tale, act iv., sc. 3.

There are other places in which Carnation is mentioned, but they refer to carnation colour—i.e., to pure flesh colour. Dr. Johnson and others have supposed that the flower is so named from the colour, but that this is a mistake is made very clear by Dr. Prior. He quotes Spenser's "Shepherd's Calendar"—

Bring Coronations and Sops-in-Wine
 Worn of Paramours.

and so it is spelled in Lyte's "Herbal," 1578, coronations or coruations. This takes us at once to the origin of the name. The plant was one of those used in garlands (*corone*), and was probably one of the most favourite plants used for that purpose, for which it was well suited by its shape and beauty. Pliny gives a long list of garland flowers (*Coronamentorum genera*) used by the Romans and Athenians, and Nicander gives similar lists of Greek garland plants, in which the Carnation holds so high a place that it was called by the name it still has—*Dianthus*, or Flower of Jove. Its second specific name, *Caryophyllus*—i.e. Nut-leaved—seems at first very inappropriate for a Grassy-leaved plant, but the name was first given to the Indian Clove tree, and from it transferred to the Carnation, on account of its fine Clove-like scent. Its popularity as an English plant is shown by its many names—Pink, Carnation, Gilliflower (an easily-traced and well-ascertained corruption from *Caryophyllus*), Sops-in-Wine (from the flowers being used to flavour wine and beer), Clove, Picotee, &c. There is an historical interest also in the flowers. All our Carnations, Picotees, and Cloves come originally from the single *Dianthus caryophyllus*; this is not a true British plant, but it holds a place in the English flora, being naturalized in Rochester and other castles. It is abundant in Normandy, and I found it (in 1874) covering the old castle of Falaise in which William the Conqueror was born. Since that I have found that it grows on the old castles of Dover, Ludlow, Deal, and Cardiff, all of them of Norman construction, as Rochester, which was built by Guthlac, the special friend of William. Its occurrence on these several Norman castles make it very possible that it was introduced by the Norman builders, perhaps as a pleasant memory of their Norman homes, though it may have been accidentally introduced with the Normandy (Caen) stone, of which parts of the castles are built. How soon it became a florist's flower we do not know, but it must have been early, as in Shakespeare's time the sorts of Cloves, Carnations, and Pinks were so many that Gerarde says :—"a great and large volume would not suffice to write of every one at large in particular, considering how infinite they are, and how every yeare, every clymate and countrey, bringeth forth new sorts, and such as have not heretofore bin written of;" and so we may certainly say now—the description of the many kinds of Carnations and Picotees, with directions for their culture, would fill a volume.

Carraways (see Apple).

Carrot.

Evans. Remember, William, focative is *carot*.
Quickly. And that's a good root.
Merry Wives, act iv., sc. 1.

Dame Quickly's pun gives us our Carrot, a plant which, originally derived from our wild Carrot (*Daucus Carota*), was introduced as a useful vegetable by the Flemings in the time of Elizabeth, and has probably been very little altered or improved since the time of its introduction. In Shakespeare's time the name was applied to the "Yellow Carrot" or Parsnep, as well

as to the Red one. The name of Carrot comes directly from its Latin or rather Greek name, *Daucus Carota*, but it once had a prettier name. The Anglo-Saxons called it "bird's-nest," and Gerarde gives us the reason, and it is a reason that shows they were more observant of the habits of plants than we generally give them credit for:—"The whole tuft (of flowers) is drawn together when the seed is ripe, resembling a bird's-nest; whereupon it hath been named of some bird's-nest."

Cedar.

- (1) *Prospero*. And by the spurs plucked up
The Pine and Cedar. *Tempest*, act v., sc. 1.
- (2) *Dumain*. As upright as the Cedar.
Love's Labour Lost, act iv., sc. 3.
- (3) *Warwick*. As on a mountain top the Cedar shows,
That keeps his leaves in spite of any storm.
1st Henry VI., act v., sc. 1.
- (4) *Warwick*. Thus yields the Cedar to the axe's edge,
Whose arms gave shelter to the princely eagle,
Under whose shade the ramping lion slept,
Whose top branch o'erspread Jove's spreading tree,
And kept low shrubs from winter's powerful wind.
3rd Henry VI., act v., sc. 2.
- (5) *Cromwell*. He shall flourish,
And like a mountain Cedar reach his branches
To all the plains about him.
Henry VIII., act v., sc. 4.
- (6) *Posthumus*. When from a stately Cedar shall be lopped branches,
which being dead many years shall after revive.
Cymbeline, act v., sc. 4; and act v., sc. 5.
- (7) *Soothsayer*. The lofty Cedar, royal Cymbeline,
Personates thee.
Thy lopped branches are now revived,
To the majestic Cedar joined.
Cymbeline, act v., sc. 5.
- (8) *Gloster*. But I was born so high
Our airy buildeth in the Cedar's top,
And dallies with the wind and scorcs the sun.
Richard III., act i., sc. 3.
- (9) *Coriolanus*. Let the mutinous winds
Strike the proud Cedars 'gainst the fiery sun.
Coriolanus, act v., sc. 3.
- (10) *Titus*. Marcus, we are but shrubs, no Cedars we.
Titus Andronicus, act v., sc. 3.
- (11) The sun ariseth in his majesty,
Who doth the world so gloriously behold,
That Cedar tops and hills seem burnished gold.
Venus and Adonis.
- (12) The Cedar stoops not at the base shrub's foot,
But low shrubs wither at the Cedar's root.
Rape of Lucrece.

The Cedar is the classical type of majesty, and grandeur, and superiority to everything that is petty and mean. So Shakespeare uses it, and only in this way; for it is very certain he never saw a living specimen of the Cedar of Lebanon. But many travellers in the East had seen it and minutely described it, and from their descriptions he derived his knowledge of the tree; but not only, and probably not chiefly from travellers, for he was well acquainted with his Bible, and there he would meet with many a passage that dwelt on the glories of the Cedar, and told how it was the king of trees, so that "the Fir trees were not like his boughs, and the Chestnut trees were not like his branches, nor any tree in the garden of God was like unto him in his beauty, fair by the multitude of his branches, so that all the trees of Eden that were in the garden of God envied him" (Ezekiel xxxi, 8-9). It was such descriptions as these that supplied Shakespeare with his imagery, and which made our ancestors try to introduce the tree into England. But there seems to have been much difficulty in establishing it. Evelyn tried to introduce it, but did not succeed at first, and the tree is not mentioned in his "Sylva" of 1664. It was, however, certainly introduced in 1676, when it appears, from the gardeners' accounts, to have been planted at Bretby Park, Derbyshire ("Gardeners' Chronicle," January, 1877). I believe this is the oldest certain record of the planting of the Cedar in England, the next oldest being the trees in Chelsea Botanic Garden, which were certainly planted in 1683. Since that time the tree has proved so suitable to the English soil

that it is grown everywhere, and everywhere asserts itself as the king of evergreen trees, whether grown as a single tree on a lawn, or mixed in large numbers with other trees, as at Highclere Park, in Hampshire (Lord Carnarvon's). Among English Cedar trees there are probably none that surpass the fine specimens at Warwick Castle, which owe, however, much of their beauty to their position on the narrow strip of land between the Castle and the river. I mention these to call attention to the pleasant coincidence (for it is nothing more) that the most striking descriptions of the Cedar are given by Shakespeare to the then owner of the princely Castle of Warwick (Nos. 3 and 4). The mediæval belief about the Cedar was that its wood was imperishable. "Hæc Cedrus, A^c sydyrette, et est talis nature quod nunquam putrescet in æqua nec in terra" (English Vocabulary—15th century); but as a timber tree the English-grown Cedar has not answered to its old reputation, so that Dr. Lindley called it "the worthless though magnificent Cedar of Lebanon."

H. N. ELLACOMBE.

(To be continued.)

NEW PLANTS.

Calliphurria subdentata.—A graceful New Granadian plant, nearly allied to *Eucharis*, of which it has the habit of growth. Mr. Baker says:—"This is a plant which has been in English gardens for many years, and in the absence of flowers has passed for *Eucharis candida*." Lately it has flowered in several places almost simultaneously, and it turns out not to be a *Eucharis* but a near neighbour of the *Calliphurria Hartwegiana*, which was figured in the "Botanical Magazine," t. 6259. It however differs from *C. Hartwegiana* in the filaments, in which the toothing is sometimes entirely wanting, so that for the botanical systematist it forms an awkward connecting link between the tribes *Amaryllideæ* and *Panicaceæ*. The *Eucharis candida* which was distributed by Mr. Bull (see THE GARDEN, 1876, plate xvi.) in 1876, is the true plant as named by Planchon. In habit the present plant could scarcely be distinguished from *Eucharis amazonica*, its bright green, ovate leaves, being borne on stout petioles 1 ft. or more in length; the flowers, which are borne in clusters of from five to seven on the apex of a slender scape, are of snowy whiteness. For the opportunity of making the annexed sketch we are indebted to Mr. T. Whellans, gardener to S. Lawrence, Esq., Clapham Park, with whom, as well as with Mr. G. R. Sheath, gardener to M. H. Beaufoy, Esq., of South Lambeth, this plant has flowered. The figure cited below gives but a slight idea of the graceful beauty of this plant.—"Botanical Magazine," t. 6289.

Restrepia antennifera.—A singular little Orchid from the New Granadian Andes, discovered in the first instance by Humboldt growing on the trunks of trees near Pasto at an elevation of 9000 ft., and since collected by other travellers in different localities in Now Granada and also in Venezuela at altitudes varying from 6000 ft. to 10,500 ft. The tufted, slender stems each bear a broadly-ovate, fleshy leaf, from 2 in. to 3 in. in length, and nearly 2 in. broad. The flowers, which are borne singly on slender scapes, are from 4 in. to 6 in. in length. The sepals and petals are lance-shaped, attenuated into slender tails, the conspicuous lip being boat-shaped and of a yellow colour dotted with red-purple behind. A plant well worth culture.—"Botanical Magazine," t. 6288.

Rondeletia Baekhousei.—A pretty pink-flowered shrub from Tropical America, whence it appears to have reached Messrs. Backhouse & Sons, of York, from the Continent, and was sent by them to Kew in 1860. Like *Cinchona* and other tropical *Rubiaceæ*, their flowers appear to be dimorphic, and in this case the stamens are conspicuous, the style being hidden deep down in the tube. It is described as a small shrub, and bears terminal clusters of delicate rosy-pink flowers fully $\frac{1}{2}$ in. in diameter. A plant well worth culture.—"Botanical Magazine," t. 6290.

Gladiolus ochroleucus.—A pretty little yellow-flowered species, a native of the Transvaal Territory and Kaffraria. It is said to grow in Grassy places at an elevation of 2000 ft. It has been imported by Mr. Bull, and although not showy, well deserves culture in a collection.—"Botanical Magazine," t. 6291.

Orychophragmus sonchifolius.—This is a singularly interesting and beautiful blue-flowering plant, herbaceous or annual, and said to be hardy. It belongs to *Crucifera*, but seems distinct from any other plant in cultivation. I have only seen imperfect flowers in a cool house, but even these were beautiful.—H. T.

TREES AND SHRUBS.

NEW WAY OF DETERMINING SPECIES OF ABIES.

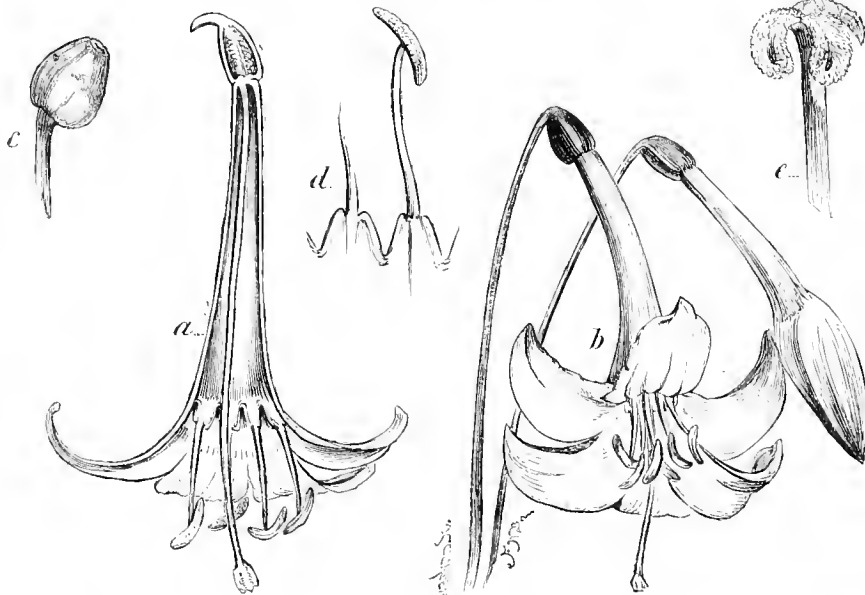

IN 1874 Dr. C. E. Bertrand, of Paris, published a work on the comparative anatomy of the stems and leaves of the Gnetales and Coniferae.* In that work, after giving an historical sketch of the literature of the subject, he describes the minute anatomy of the leaves of most of the important genera, and in many cases gives synoptic tables by which the species of certain of the genera may be determined. In the present essay I propose to state very briefly the results of an independent investigation, made during the past eighteen months, on the anatomy of the leaves of the various species of *Abies* of Link (*Picea*, Don), and *Pseudotsuga*, Carrière (*Abies* of authors). In so doing, I hope to be able to correct many errors that Bertrand seems to have committed, owing probably to the imperfection of the materials at his command; and, further, to throw some light on the obscure synonymy of this extremely interesting group of plants. In examining the structure of the leaves of the species of *Abies*, it is chiefly necessary to obtain good transverse sections from the middle of the leaf. These must be thin and accurately cut, and are best rendered suitable for careful examination by being placed in a solution composed of equal parts of glycerine and water. The slices require to be examined with a moderate magnifying power, say of from 80 to 100 diameters. The chief points to notice in the transverse section are the following:—First, carefully examine the central midrib or vein of the leaf. It consists, in *Abies*, of a pair of fibro-vascular bundles, placed in general very close together, and exhibiting distinctly two wood portions, one belonging to each of the separate bundles. *Abies* can be at once separated from *Pseudotsuga* and *Tsuga* by this character, as in both of these the bundle is single, only one wood portion being visible. Second, observe the sheath of delicate parenchymatous cells surrounding the single or double bundle. It is a single layer of cells, very different from the tissue of the mesophyll or ground tissue of the leaf on the

cellular tissue is loose, with many intercellular spaces communicating with the stomata of the under surface. On the upper side the chlorophyll-bearing cells are generally placed so as to form two zones or more of the palisade tissue; if, however, stomata be present on the upper side, then the palisade tissue is interrupted, and the loose tissue, with the usual intercellular spaces, will be noticed. Fourthly, in the mesophyll, two resin canals will be found, their position varying in different species. The resin canal is an intercellular canal, surrounded by a zone of small, rather thick-walled cells. The canals are, in one series, placed in the middle of the parenchyma, and run from base to apex of the leaf parallel to the midrib, but about equidistant from the midrib and margin, and also nearly equidistant from the upper and under sides of the leaf. In another series the resin canals are placed very close to the epidermis of the under side of the leaf, running parallel and close to the margin of the leaf. The resin canals are very conspicuous objects in the transverse section, and are of great importance in separating the different forms. Fifthly, the epidermis of the upper and lower surfaces of the leaf, and the cells immediately beneath it, have to be carefully examined. The epidermis consists of a single layer of cells with thick walls, and externally provided with a well-developed cuticle. It

also bears the stomata in rows, the rows forming very definite white bands on the under surface, one on each side of the midrib. When stomata are present on the epidermis of the upper side, they generally occur in long rows, sometimes over the whole surface, or limited to the upper half or third of the leaf; or, lastly, may form a narrow band down the whole centre of the leaf above the midrib. Beneath the epidermis a series of thickened cells is generally developed. These belong to the ground tissue of the leaf, and have nothing to do morphologically with the epidermis. These thickened cells form a continuous, or interrupted, or scattered series called the hypodermis, and in a few rare cases they are wanting altogether. The study of the minute anatomy of the leaf, as shown by making a simple transverse section of the fully-developed leaf, cannot fail to be useful to all arboriculturists. After the

Calliphurria subdentata (reduced figure of the plant). (See p. 278).

Calliphurria subdentata.—a, section of flower; b, flower and full-sized bud, natural size; c, ovary, enlarged; d, stamens, enlarged; e, stigma, enlarged. (See p. 278).

one side, and from the cells of the fibro-vascular bundles on the other. Thirdly, the general parenchyma of the leaf is to be scrutinised. If stomata be developed on one side of the leaf only, that is, on the under side, then the Chlorophyll-bearing

examination of several hundreds of specimens, native and cultivated, I can testify to the permanence of the characters, and to their value in separating many closely related forms. It must be kept in mind, however, that attention must be paid to the proper selection of the leaves for examination. They must be full grown, and from plants of some

* "Anatomie comparée des tiges et des feuilles chez les Gnétacées et les Conifères," par C. E. Bertrand, Paris: G. Masson, 1874.

size, as the leaves of very young specimens (say two or three years old) often differ from those of mature ones. The differences in the structure of young and old leaves generally have a certain relation. Thus a species, which has no hypoderma in the mature leaf, will not have any in the young leaf; and a leaf, with a continuous zone of hypoderma, when mature, will have a more or less interrupted one in the young leaves. In a few cases the position of the resin canals seems a little variable in the young and old leaves. This has been observed in a few cultivated forms, as *Abies bifolia* (A. Murray), *Abies firma* of gardens, and in *Abies Pichta* of gardens. In some of the species, two kinds of leaves are produced, those in the ordinary vegetative shoots being different from those on the cone-bearing axes. This is very well marked in *Abies bifolia* (Murray), hence the specific name; also in *Pseudotsuga magnifica* and *nobilis*, and probably also in *A. Pinsapo*, but I have not been able to examine the cone-bearing shoot of an authentic specimen. In this essay I propose to take Parlatore's species, as described in De Caudolle's Prodrômus, and make some remarks on the synonymy. It will be necessary to depart from his arrangement somewhat, as it is of importance to separate the anatomically distinct species belonging to *Pseudotsuga* (of which *A. nobilis* is the type) from *Abies*. It is also impossible to give full details of the microscopic structure of the leaves of each species, as that would require more space than I have at my disposal, and would need numerous drawings to render the description intelligible. It is less necessary, as a full account of the structure of these plants will shortly be published in another place.

Abies, Link (*Picea*, Don, London).

1. **Pinus (Abies) bracteata**, Don, Parlatore; *Abies bracteata*, Hooker & Arnott.—Most nearly related anatomically to *A. religiosa*, but distinguished by the form of the leaf and by the non-resinous, yellow bud-scales, as well as by the conspicuous difference in the cones. Several cultivated and native specimens have been examined. The characters are very uniform, and, as far as observation goes, it is a plant that does not vary in appearance or in the structure of the leaf. Leaves pointed, stomata on under side of leaf only. Resin canals close to the epidermis of the under surface. Hypoderma forming a continuous zone under the epidermis of the upper side.

2. **Pinus (Abies) Fraseri**, Parsh.—Most closely related anatomically to *A. balsamea*, from which it can be distinguished by the appearance and position of the leaves, as well as by the very distinct cones. Although placed close to *bracteata* and *religiosa* by Parlatore, it is in no way related anatomically to these species. I have only examined one living specimen of this species, kindly sent to me by Mr. Fowler, from Castle Kennedy; and have examined a cone (without leaves) in the Museum, Royal Botanic Garden, Edinburgh, presented by Mr. Fowler, and grown at Castle Kennedy. Specimens from Kew Herbarium have also been examined—one from the summit of the Hoosack Mountains, Massachusetts; another from Canada; and a third from Newfoundland, named *Pinus americana*; but I am rather doubtful of the two last, as some leaves of *Fraseri* and *balsamea* approach each other exceedingly closely anatomically, and are not readily separated when dried specimens only are consulted. Leaves short, blunt at the points. Stomata on both sides of the leaf. Hypoderma slightly developed under the epidermis of the upper side. Resin canals in the parenchyma of the leaf.

3. **Pinus (Abies) religiosa**, Humb.—Most closely related anatomically to *A. bracteata*, but distinguished by the form and arrangement of the leaves, by the very resinous yellow bud-scales, and also by the cones. Living specimens have been examined from Glasnevin Garden, Dublin. An authentic specimen of *Abies hirtella* was examined from Kew Herbarium; it differs in having the leaves blunt and emarginate, and having only a few large, scattered hypoderm cells. As some of the leaves from the rather unhealthy plant in Glasnevin Garden exhibited a similar character, I am not disposed to consider *hirtella* a distinct species. Leaves long, sharp at the points; stomata on the under side of the leaf only. Hypoderma, forming a continuous, or only slightly interrupted, layer under the epidermis of the upper surface. Resin canals close to the epidermis of the under side of the leaf. *Pinus (Abies) Abies*, DuRoi.—As Parlatore unites *Abies pectinata*, De C.; *Abies Nordmanniana*, Spach.; *Abies Cephalonica*, Loudon; *Abies Apollinis*, Link; and *Abies Reginae-Amalie*, Heldr.; and makes them either synonyms or varieties, I must depart from his arrangement.

4. **Abies pectinata**, De Caudolle.—All the specimens of *A. pectinata* examined have the resin canals in the parenchyma of the leaf, and are thus at once separated from *A. Nordmanniana*. Leaves rounded or emarginate at the apex; stomata on the under side of the leaf only; hypoderma forming a very slightly interrupted layer under the epidermis of the upper side of the leaf; resin canals in the parenchyma of the leaf.

5. **Abies Nordmanniana**, Spach.—Closely related to *A. pectinata*, but has the resin canals in a different position. Leaves emarginate at the apex; stomata on the under side of the leaf only; hypoderma forming a slightly interrupted layer under the epidermis of the upper side of the leaf. Resin canals placed close to the epidermis of the under side.

6. **Abies Cephalonica**, Loud.—Very different from *A. pectinata*; more nearly related to *A. Nordmanniana*, but at once separated by the enormous development of hypoderma. *A. Apollinis*, Link, and *A. Reginae-Amalie*, Heldr., have both been examined. They can hardly be considered anatomically as being anything more than slight varieties of *A. Cephalonica*, having a slightly less development of hypoderma, and having the stomata more constantly present on the upper side of the leaf. Leaves pointed at the apex; stomata rarely forming a row or two on the upper surface of the leaf, generally confined to the lower; hypoderma well developed, forming a zone two or three cells thick under the whole epidermis of the upper side; resin canals placed close to the epidermis of the under side.

7. **Pinus (Abies) cilicica**, Antoine.—This Fir is extremely closely related anatomically to *Abies Nordmanniana*, but as I have not had the opportunity of examining an authentic cone-bearing shoot, I shall consider them quite distinct. Leaves obtuse and emarginate at the apex; upper surface with no stomata; hypoderma well developed, but consisting of rather scattered cells; resin canals near epidermis of lower side.

8. **Pinus (Abies) Pinsapo**, Boiss.—Living specimens only of this have been examined; and I have not been able to examine leaves from an authentic cone-bearing shoot. Related, although distantly, to *A. Nordmanniana* and *A. Cephalonica*, more nearly to *A. Baborensis*, but in all respects a remarkable, distinct form. Leaves projecting all round the stem, short, rigid, with a very sharp point; upper surface with six or eight rows of stomata, placed rather distantly over the whole surface, below with a band on each side of the midrib. Hypoderma well developed, often two or three cells thick, but forming a zone, interrupted by the stomata. Resin canals close to the epidermis of the under side.

9. **Abies Baborensis**, Coss (*Pinsapo*, Parlatore in part; *Abies Numidica*, De Lannoy).—Somewhat intermediate between *Pinsapo* and *Nordmanniana* in appearance, but differing anatomically in the presence of stomata on the upper side, and in the scanty development of the hypoderma. It is cultivated under the names of *Numidica* and *Baborensis*. Leaves short, blunt, or emarginate at the apex, above with one or two short rows of stomata near the apex, below with a band on each side of the midrib. Hypoderma scanty. Resin canals close to the epidermis of the under side.

10. **Pinus (Abies) balsamea**, Linn.—Closely related to *A. Fraseri*, and not easily separable anatomically. The cones of *A. balsamea* and *A. Fraseri* are sufficiently distinct. Leaves short, apex emarginate; upper surface with two or more rows of stomata in the middle line, near the apex, below with a band of stomata on each side of the midrib. Hypoderma wanting. Resin canals in the parenchyma of the leaf. *Pinus (Abies) firma*, Parlatore (not Antoine).—Parlatore gives *Abies bifida* and *Abies homolepis* as synonyms of his *P. firma*. In this I cannot concur.

11. **Abies firma**, Sieb. & Zucc. (not Parlatore).—Only two specimens of *firma* have come under my notice, both of them in Kew Herbarium, and named *firma*, Sieb. & Zucc. One was sent from Nagasaki, Japan, by Oldham, in 1862; the other was collected in Japan, Nippou, by Maximowicz in 1861. It is not in cultivation, all the plants I have seen under this name being *A. bifida*. *Abies homolepis*, Sieb. & Zucc., sunk by Parlatore as a synonym of *firma*, I have not seen; but, according to Bertrand, it only differs from *A. firma* in having fewer stomata on the under surface of the leaf, a character of no importance. *Abies brachyphylla*, Maximowicz, (*Pinus brachyphylla*, Parlatore), is anatomically the same as *Abies firma*. Leaves slightly wider near the apex than above the base, apex rounded and emarginate. A few stomata occasionally in a patch on the upper surface near the apex, below with a band on each side of the midrib. Hypoderma well developed. Resin canals in the parenchyma of the leaf.

12. *Abies bifida*, Sieb. & Zucc.—I have received the plant under the name of *bifida* from the Royal Botanic Garden, Edinburgh, and have compared it with an authentic specimen in Kew Herbarium. A narrower-leaved form is also cultivated (without a name) in the Edinburgh Garden. It is the form cultivated as *Abies firma*, and has been sent me under this name from Messrs. Veitch, and from Castle Kennedy. Mr. Fowler sent me a "late variety," in one of the leaves of which there was a slight abnormality, the resin canal of one side being slightly distant from the epidermis. Leaves tapering towards the bifid apex; no stomata on the upper surface, below with a band on each side of the midrib. Hypoderma well developed. Resin canals close to the epidermis of the lower side of the leaf. Parenchyma of the mesophyll of the leaf with numerous scattered, elongated, unbranched, greatly thickened, liber-like cells (idioblasts), quite peculiar to this species. Pinnus (*Abies*) *holophylla*, Parlatores. —One of Maximowicz's species, of which I have seen neither living nor dried specimens. Since the above was written I have been able, through the kindness of Professor Oliver, F.R.S., to examine an authentic specimen of *A. holophylla*, Maxim., from Kew Museum. It is a distinct form, not yet in cultivation. Pinnus (*Abies*) *holophylla*, Parlatores.—The examination of an authentic specimen in Kew Herbarium, *Abies brachyphylla*, Maxim., Japan, Yokohama, 1862, shows that *A. brachyphylla*, Max., is *A. firma*, Sieb. & Zucc. (not Parlatores), while *A. firma*, Parlatores (not Ant.), seems to have been described from a mixed set of specimens of *firma* and *bifida*.

13. *Pinus* (*Abies*) *Pindrow*, Royle.—Closely related anatomically to *A. Webbiana*, and differing more in the outline of the transverse section than in the actual structure. Living specimens from Glasnevin Garden and Elvaston Nurseries have been examined. Leaves long; apex bifid, with two narrow sharp points. No stomata on the upper surface of the leaf. Hypoderma forming an interrupted layer of cells. The margin of the leaf sharp. Resin canals close to the epidermis of the lower side of the leaf.

14. *Pinus* (*Abies*) *Webbiana*, Wall.—Closely related to *A. Pindrow*. A third form has come under my notice, the first specimen in the Herbarium of Trinity College, Dublin, from the Himalayas, named *A. Webbiana*, from Hooker fil. and Thomson's collection; and a second specimen of the same thing bearing a cone, from Royal Botanic Garden, Edinburgh, and named *A. Pindrow*. Both these are distinguished by the position of the resin canal, which is in the parenchyma of the leaf. It requires further investigation. Leaf slightly contracted towards the bifid apex, the two portions either small and very sharp, or slightly rounded. No stomata on the upper side of the leaf. Hypoderma forming an interrupted layer of cells. Margin of the leaf rounded. Resin canals close to the epidermis of the lower side of the leaf.

15. *Pinus* (*Abies*) *sibirica*, Tarcz.—Cultivated in the Royal Botanic Garden, Edinburgh, and in the Glasnevin Garden, Dublin, under the name of *A. Pichta*. Also received from Elvaston Nurseries as *A. sibirica*. Anatomically a most distinct species, most nearly related to *A. balsamea* and *Fraseri*, but at once distinguished by the form of the leaf, the total absence of any trace of hypoderm cells, and the absence of stomata on the upper surface of the leaf. Leaves with the apex rounded or slightly truncate. No stomata on the upper surface. Hypoderma wanting. Resin canals in the parenchyma of the leaf.

16. *Abies amabilis*, Douglas (not Parlatores).—Many specimens of this species have been examined. It is the *amabilis* of gardens, the *Abies grandis* of *A. Murray* ("Synonyms of Various Conifers," p. 18), who figures the peculiar arrangement of the leaves (Op. Cit., p. 19, fig. 20). It is cultivated in the Royal Botanic Garden, Edinburgh, at Elvaston Nurseries, and by Mr. Anthony Waterer, as *amabilis*. Three specimens in Kew Herbarium, collected by Dr. Dyall, have also been examined. On the Continent it is known as *Abies spectabilis*, Herpin de Fremont, (teste, Bertrand). Parlatores confounds it with *lasiocarpa* of Hooker and *Abies bifolia* of Andrew Murray, the description given by Parlatores referring to *bifolia* (Murray). This species was sent home by Jeffrey as No. 409, and was described and figured as *Picea lasiocarpa* (Balfour). No plants seem to have grown from Jeffrey's seeds, as all the plants called *lasiocarpa* are *grandis*. The examination of the original specimen in the Museum, Royal Botanic Garden, Edinburgh, enables me to state with confidence that *A. lasiocarpa* (Balf.) is *A. amabilis* (Dougl.). Mr. Murray's figures (Op. Cit., p. 31, figs. 1 and 2) also prove the same thing. *A. lasiocarpa* (Hook.) is a distinct thing, and equals *A. bifolia* (*A. Murray*), *A. amabilis* (Parlatores). Leaves rounded and emarginate at the apex, peculiarly arranged, forming two lateral rows, and those on the upper side of the shoot twisted so as to bring their upper surfaces superiorly, and placed with their axes nearly parallel to the long axis of the shoot. No stomata on

the upper surface. Hypoderma well developed, forming a thick, slightly interrupted layer of cells. Resin canals close to the epidermis of the under side of the leaf.

17. *Abies lasiocarpa*, Hooker (not Balfour); *A. bifolia*, *A. Murray*, Syn. var. Conif., p. 31; *A. amabilis*, Parlatores, (not Dougl.)—Very different anatomically from *A. amabilis*, with which it is confounded by Parlatores. It was confused by the Oregon Committee and Jeffrey with *Pseudotsuga magnifica*, both plants being mixed in Jeffrey's (No. 1180) in the Museum, Royal Botanic Garden, Edinburgh. I have examined Hooker's type specimen in Kew Herbarium, a specimen sent by Douglas in the same Herbarium, five specimens from the Oregon Boundary Commission collected by Dr. Lyall in 1860-61, with the native name "Marielp." It is also *P. bifolia* of Murray. I have examined specimens from M. Roezl, sent to me by Mr. Syme. The only living plants observed were seedlings from Elvaston Nurseries. None of the seeds sent out by the Oregon Committee seem to have germinated. A glance at the figures of the bracts given by Mr. Murray in his work already quoted, p. 31, figs. 1 and 12, will show that *lasiocarpa* (Hook.) equals *bifolia* (Murray). Leaves of two kinds, those on the vegetative branches rounded or emarginate, on the cone-bearing shoots sharp and pointed. Stomata on both sides of the leaf. Hypoderma well developed. Resin canals in the parenchyma of the leaf.

18. *Pinus* (*Abies*) *concolor*, Engel.—A very distinct form, related to *Lowiana* and *grandis*, and more distinctly to *amabilis*. I have only seen dried specimens from Engelmann (No. 828) in the Herbarium at Kew and Trinity College, Dublin, and have not as yet seen it in cultivation in this country. Bertram (Op. Cit., p. 90) gives the anatomical characters of *A. concolor* as those of *grandis* (Lindl.), and cites *grandis* and *lasiocarpa* as synonyms, *grandis* of Douglas being Bertrand's *Gerdouiana*. Leaves obtuse at the apex, closely covered with stomata on both sides. Hypoderma scanty. Resin canals touching the epidermis of the under side of the leaf.

19. *Pinus* (*Abies*) *grandis*, Dougl.; *Abies amabilis*, *A. Murray*; *Abies Gordoniana*, Carrière; *Abies lasiocarpa*, Hort. (not Balf. or Hooker).—A very distinct form (No. 393 of Jeffrey), the scale of which is figured by Mr. Murray (Op. Cit., p. 25, fig. 32). Known commonly in gardens under the names of *grandis* and *lasiocarpa*. It is *A. Gordoniana* of Carrière and Bertrand. This species can be distinguished with the greatest ease from all its allies by the hypoderma of the leaf, as well as by the bracts of the cone. Leaves obtuse and emarginate at the apex, without stomata on the upper surface (very rarely with two or three in a small cluster near the apex). Hypoderma consisting of a few scattered cells under the upper epidermis. Resin canals touching the epidermis of the under side of the leaf.

20. *Abies Lowiana*, Murray; *Picea Lowiana*, Gordon; *Pinus* (*Abies*) *grandis*, Parlatores in part; *Picea Parsonsi*, Hort.; *Picea lasiocarpa*, Hort.—Closely related to *Abies grandis*, but distinct. Separated by the different development of hypoderma, by the presence of the stomata on the upper side, and, when growing, by the paler, more yellow colour of the young leafy axes. It is cultivated extensively, and passes under different names, such as *Lowi*, *Lowiglanca*, *Parsonsi*, and *lasiocarpa*. Then it was described in 1862 by Mr. Gordon as *Picea Lowiana*. Leaves long, narrow, obtuse or emarginate at the apex, with a broad band of stomata on the upper surface, running in the middle line from base to apex. Hypoderma well developed. Resin canals touching the epidermis of the under side.

21. *Pinus Abies Veitchi*; *Pinus selenolepis*, Parlatores; *Abies Veitchi*, Carrière; *Picea Veitchi*, Lindl.—Only a single specimen of the remarkably distinct form has been seen. It is in Kew Herbarium, and bears two labels, "*Abies microserma*," and "*Picea Veitchi*," (Lindl.). It has nothing to do with the *Abies Veitchi* in cultivation. Leaves obtuse and emarginate at the apex. Stomata on the under surface of the leaf only. Hypoderma wanting. Resin canals in the parenchyma of the leaf.

22. *Abies Harryana*, new species; *Abies Veitchi*, Hort., Veitch, not of descriptions.—This is the plant cultivated as *A. Veitchi*, and sent to me under that name by Messrs. Veitch. It differs in appearance from true *Veitchi*, and can be at once separated anatomically by the great development of the hypoderma, and by the position of the resin canals. If farther investigation confirm the opinion that it is new, the name *Harryana* will be retained in compliment to Harry J. Veitch, Esq., the head of the firm of Veitch & Sons, in London. Leaves acute at the apex. Stomata on the under surface of the leaf only. Hypoderma forming a continuous or almost continuous layer under the epidermis of the upper side of the leaf. Resin canals touching the epidermis of the under side.

23. *Abies* sp., from Drummond.—A single plant, in the Royal Botanic Garden, Edinburgh, has been examined, and I fail to refer it to any of the forms already noticed.

Pseudotsuga, Carrière.

Leaves not in cushions, but inserted directly into the stem, as in *Abies*. Two resin canals, one on each side of the leaf. Fibro-vascular bundle single.

1. *Pinus (Pseudotsuga) nobilis*, Dougl.; *Abies nobilis*, Linn.; *Picea nobilis*, Loudon.—Very many specimens of *P. nobilis*, native and cultivated, have been examined. The leaves are rather variable, being flattened in young plants, and on the cone-bearing shoots approaching that of the next species, *P. magnifica*. Leaves projecting upwards on the upper side of the shoot; leaf with an obtuse apex; stomata on both sides of the leaf; leaves on the vegetated shoot furrowed on the upper side; hypoderma chiefly developed at the margins of the leaf and below the longitudinal furrow; resin canals close to the under surface of the leaf.

2. *Pinus (Pseudotsuga) magnifica*; *Abies magnifica*, A. Murray; *Abies amabilis*, Parlatore; *Abies robusta*, Hort.—Many specimens of this have been examined, both cultivated and native. The specimens from Lobb are in Kew Herbarium. It was also sent home by Jeffrey (No. 1480, part), and is extensively cultivated in the Royal Botanic Garden, Edinburgh, under the names *magnifica* and *robusta*. It is very closely related to *P. nobilis*, but separated at once by the short bracts of the cone. The bracts are well figured by Mr. Andrew Murray, Syn. of var. Conif., p. 28, fig. 42. It is difficult to understand how Parlatore could have confounded it with his *P. amabilis*, and it seems inexcusable when he had Mr. Murray's most excellent figures before him. A specimen of *amabilis* (Douglas) in Kew Herbarium, and sent to me by Professor Oliver as the type of Douglas' species, is either *magnifica* or *nobilis*, so that some confusion must have been made at a very early time. Further investigation will, however, be made on this point. Leaves rounded or acute at the apex, more or less tetragonal, not grooved on the upper surface; stomata on both sides of the leaf; hypoderma well developed; resin canals close to lower epidermis, surrounded by hypoderma.

3. *Pseudotsuga Davidiana*, Bertrand.—A species from Thibet, unknown to me, and described by Dr. C. E. Bertrand, Op. Cit., p. 82. It is not in cultivation.

4. *Pinus (Pseudotsuga) Douglasi*, Sabine.—The characters of specimens of *Douglasi* seem variable, and I have seen two distinct plants under this name. The large plant in the Royal Botanic Garden, Edinburgh, may be taken as the type of the one form. The other I have only seen Herbarium specimens of, one from Kew, and two from the Herbarium of Trinity College, Dublin. These latter—the Herbarium specimens—are all distinguished by the presence of remarkable, star-like, thickened cells of large size lying in the parenchyma of the leaf. The specimen from Kew Herbarium is from the Rocky Mountains, and marked *Douglasi*. The next, from Trinity College Herbarium, is from New Mexico, C. Wright (No. 1885). The third is from the same Herbarium, and was collected by Fendler in New Mexico (No. 829). Parlatore cites this plant as belonging to *P. amabilis*, but it is anatomically identical with Wright's specimen referred by Parlatore to *Douglasi*. Further observation is wanted to clear up the difficulties in the synonymy.

5. *Pinus (Pseudotsuga) Fortunei*, Parl.; *Abies Fortunei*, Lindl.; *Abies Jezoensis*, Hort.—A very distinct form, closely related to *Abies Veitchi* (Hort., Veitch), *A. Harryana* mihi, differing only in the larger leaf and single fibro-vascular bundle. I am indebted to Messrs. Veitch for the only living specimen I have seen. It is well described and figured by Mr. Andrew Murray in his "Sketch of the Conifers of Japan." Leaves long and pointed. No stomata on the

upper side of the leaf. Hypoderma not very well developed. Resin canals close to the lower epidermis.—Dr. McNAB in "Proceedings of the Scottish Arboricultural Society."

Berberis Darwini and its Uses.—This is one of the hardiest and most beautiful of the family to which it belongs, and one which certainly ought to find a place in every shrubbery, however small. About a month ago I saw a large plantation of this Berberry in a nursery, and noted great differences amongst the plants as regards the time of flowering. In some the blossoms were dropping off, others were just unfolding them, whilst the buds of a later section were scarcely visible. There is a successional character about the flowering of this *Berberis* that does not exist, so far as I have noticed, in the others. What a delightful wall plant it makes! A stretch of low wall covered with it at this season and earlier would be a sight worth seeing, and the long sprays, loaded with small golden balls, are not bad subjects for indoor or room decoration. Even when not in flower, its neat foliage and bushy habit make it one of the most useful and attractive of low-growing, evergreen shrubs.—E. HOBDAV.

Simple Materials for Artistic Planting.—We search the world over for "new" things, and it is well, for the greater the store of valuable trees and shrubs the more beautiful of course will our garden pictures be; but there is one thing that is quite as much to be desired, and that is the knowledge to make the most of many simple materials in abundance around us. Take, for example, such trees as the Birch and the Lombardy Poplar—trees abundant everywhere. One could not desire more beautiful objects or those which give more striking effects when properly placed, yet how seldom do we see such materials used as an artist would use them, though the planter may be an artist, too, in his own way, and has the advantage of dealing with the natural objects and not with pigments representing them. In addition to such well known subjects as the above, there are many others equally useful, but which are rarely ever used intelligently, as, for example, the Osier, with its showy twigs which look so bright in sun or shower. We desire not, however, to pick out all such subjects as deserve attention (the catalogues of our tree and shrub nurseries contain the names of many), but rather to insist on the need of so arranging each subject that the fullest expression of its beauty may be obtained.

The pell-mell universal mixture of our gardens is their ruin. There are many and various ways of remedying this; some trees, where there is abundant room, may be seen to greatest advantage in groves; others in groups, others singly, some in all three ways. The mixed system itself, if judiciously carried out, would be an agreeable change. Apart from this consideration, however, and more important still, is the disposition of the trees in relation to others near, or to lawns, or water, or rocks, or soil, or climate. But underneath all the varying conditions that may arise, one rule may be safely kept in mind, and that is, that only real and lasting success can arise from planting when each subject used, be it common or rare, is so placed that it may in time show all the beauty and character that belong to it.

PARK TREES.

WHITE AND SCARLET THORNS form excellent park trees, making shapely heads, and attaining a good size, though they can hardly be said to be timber trees. As they are rather slow-growing subjects, good, tall-stemmed trees may be planted in groups here and there in association with them, and they should be protected from cattle for a time by means of a wire fence. Paul's Scarlet Thorn is the best of its class, and should find a place in every collection. Beech, Horse Chestnut, and several others are favourites as park trees; but cultivators entertain an objection to the Spanish Chestnut in plea-

Grove of Poplars at Ermenonville.

sure grounds from its habit of casting its leaves during summer; that is, however, a trifling matter, considering the highly ornamental character of the tree, which is one of the best that can adorn a lawn, but it must have room all round it. The Weeping Birch is another subject highly deserving of a good position in all ornamental grounds. The general impression with regard to the Birch is that it is too thin-habited a tree when planted singly for ornamental purposes; but this does not apply to the true Weeping variety, which is perfectly symmetrical in shape and particularly graceful in habit, the branches even in old trees, drooping right down to the ground. Some of the finest Weeping Birches in this country stand, we are informed, on the banks of the river Findhorn, in Morayshire: they are very lofty, and the branches exhibit pendent masses of spray 10 ft. in length. The Weeping Birch is a very beautiful riverside tree. When planted on lawns the Grass should not be cut too closely about its roots, as they run quite near to the surface, a long way from the trunk, and when they are wounded about the time of the rising of the sap they bleed profusely; in fact, the Birch may be tapped like the Sugar Maple. A hole bored about 2 in. deep in a stout limb will yield nearly half-a-dozen quarts of sap 'in a day, and it is wholesome to drink. Trees of the Weeping Birch form round or rather conical heads when planted singly, and the branches droop gracefully to the ground; but they are also very ornamental when planted in masses about lake sides and rivers, and they may often be introduced with excellent effect among other trees, their pendent masses of foliage associating well with most other kinds of vegetation. It is hardly necessary to speak of the hardiness of the Birch, for, as is well known, all the varieties of it are natives of temperate or cold regions. In the highlands of Scotland, and in upland and cold districts elsewhere in this country, it is a rapid-growing tree, and the wood is excellent for various purposes, particularly for making charcoal. We have plenty of tried subjects for planting amongst our English forest trees without resorting to doubtful novelties. Compare, for example, the common Silver Fir and the common Spruce with some rare species. Neither the Silver Fir nor the Spruce is reckoned of much account as an ornamental tree; nevertheless, when planted in suitable situations, in a damp climate, and in a tolerably moist soil, either of them—especially the Silver Fir—far surpass some of the more recent and popular introductions. Both are perfect in their shape, grow nearly 100 ft. high, and retain their branches, even when grown thickly together, down to the very ground. Thousands of such examples are to be seen in the valleys of the west of Scotland. Then among other park trees we have the Holly; it will grow 40 ft. high, and nearly half as wide, if it have room, and be perfect in shape, and when covered with fruit it cannot be surpassed. We have seen such specimens that were valued more than any other tree in the grounds. Why is it not planted in our parks more extensively instead of in hedgerows, and as underwood only? Is it because its capabilities are not understood? If any one who reads this has a fairly-shaped tree and will move it next May to a tolerably sheltered situation, providing a bit of good soil for it if the land be naturally poor, they will see what it will do in a year or two. Whatever trees are employed to form groups or single specimens, it must never be forgotten that they must be planted with that object, and not crowded together, or, if they have originally been planted thickly, early thinning must be attended to.

CHEF.

RULES FOR WILLOW PLANTERS.

1st. Never transplant a Willow if a cutting can be used, for all Willows succeed better from cuttings than they do from rooted plants. 2nd. After planting, keep them clean; never allow weeds to choke or overpower them. 3rd. No Willows do well in water-logged land, nor in peat bog, nor in dry sandy soil. The best soil for an Osier plantation is a strong loam, and the most favourable position where they can be flooded at will and yet the land be well drained. 4th. In England, Willows may be planted at any time from the middle of November to the end of March. 5th. If practicable, break up the ground by a steam cultivator, which is cheaper than ordinary trenching, and quite as good. This should be done early, to ensure the ground being in good condition for planting, for if cuttings be stuck into unbroken clods, failure may be expected. 6th. In planting basket Willows secure, at whatever cost, the best sorts, and free from mixture, taking care that the species is suited to the soil, and adapted to the market; it is false economy to plant whatever comes convenient (a mixed crop is always of small value), and a Willow plantation in suitable soil will last from fifteen to thirty years. 7th. When cuttings are planted with the view to grow into timber trees, cut to the ground, at the end of the first season, all crooked and defective shoots, for the first year's shoots seldom grow straight enough to be allowed to stand for timber trees. 8th. Protect all young plantations from ground game, for even the buds of bitter

Willow are not proof against rabbits or hares. 9th. Never pollard a Willow; pollard Willows decay, and, in that state, harbour destructive insects; better and straighter poles are obtained by cutting to the ground. 10th. Willows make good wind screens or nurse trees; and the Long-leaved Salix or *Salix acuminata* stand well on the sea coasts or other exposed situations: some of the varieties of this species make good poles for fencing or general farm purposes, but they are not otherwise commercially valuable. 11th. After cuttings are put into the ground let the latter be firmly trodden down around them; many cuttings die from this being only partially done. 12th. Do not plant cuttings when the bark is much chafed or broken; on the contrary, throw them aside. 13th. Do not plant little corners with basket Willows and expect such scraps to pay; it would be just as reasonable to plant a rood of ground with Wheat and expect to make a profit out of it: if such bits are to be planted, plant them for poles or timber; in this form they will pay well, but they can never pay to cultivate for basket Willows. 14th. Willows will grow on land occasionally overflowed by salt water, provided it is suitable in other respects. 15th. In collecting Willows for scientific observation or classification, avoid decision until you have grown them in a trial ground and compared them with others similarly situated, Willows being so much altered by soil, situation, and climate as to be unrecognisable even by those who have studied them for years: if this plan be adopted, much of the confusion that now exists will be avoided, and many of the so-called species will be found to be only varieties. 16th. Willows planted on the banks of rivers are of great value in preserving the soil from being washed away, by reason of the grasp and tenacity of their long fibrous roots. 17th. At the present price of cuttings and labour, the outlay for planting basket Willows, including everything, may be stated at 25s. per 1000 cuttings, which at 20,000 cuttings per acre—the ordinary quantity—would be £25, and, unless under very exceptional circumstances, this may be taken as the ordinary cost of forming an Osier plantation. 18th. The importance of planting quick-growing timber trees in a country so limited in area as ours, is admitted; and the Willow is not only one of the best trees for this purpose, but no wood sells more readily, nor is so difficult to obtain, nor will yield a greater return. 19th. All cuttings should be pushed from 8 in. to 10 in. into the soil, and in a slanting direction. 20th. The number of cuttings required for an imperial acre is as follows:—18 in. each way, 19,360; 21 in., 10,800; 36 in., 4848; 48 in., 2722.—WILLIAM SCALING, *Basford, Notts.*

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 5.

This meeting, which was a very interesting one, was well supported, admirable groups of Orchids, fine-foliated plants, and spring-blooming shrubs being contributed by the principal trade growers. The Orchids, Crotons, and Gloxinias from Messrs. Veitch & Sons, the well-flowered Rhododendrons sent by Messrs. Lane, and the artistic group of decorative plants arranged by Mr. John Wills, were especially effective; as were also some choice Orchids furnished by Mr. Michaels, Mr. W. Terry, and Sir Trevor Lawrence. Messrs. J. Standish & Co., Ascot, had a beautiful group of double-white Azaleas and Lily of the Valley, fringed with well-grown plants of the new Maiden-hair Fern (*Adiantum gracillimum*); and very attractive groups of miscellaneous plants came from Mr. B. S. Williams, Messrs. Rollisson, and others.

First-class Certificates.—These were awarded to the following new plants:—

Clematis Aurora (Noble).—A semi-double flower of the J. Gould Veitch or Fortunei type, having lance-shaped segments of a rosy-colour shot with lilac. The plant exhibited was but a small one, and only bore a solitary flower; when better established, however, it will doubtless prove more floriferous.

Primrose, Brilliant (R. Dean).—A bold and distinct variety, the rich, full, crimson-tinted petals surrounding a bright golden centre or eye. The plant is robust in habit, and its flowers are well elevated on stout stalks. It is a valuable addition to dark-coloured, hardy Primroses.

Cyclamen persicum, Brilliant (R. Clarke).—A compact-habited plant, its heart-shaped leaves being distinctly marbled with silvery-grey on a darker ground. Its flowers are rather small, but wonderfully dense and vivid in colour, their tint being midway between ruby and crimson-purple. It is well worth culture as a seed-parent, and contrasts well with the paler-tinted kinds.

Dendrobium sculptum (Sir T. Lawrence).—This plant belongs to the D. speciosum section, which it closely resembles in growth, except in being more slender. The flowers are borne in clusters of five or six together, the sepals and petals being pure white, and the saddle-shaped lip flat with a blotch of orange in the centre. The flowers are 2½ in. wide and delicately fragrant.

Nephrolepis Duffii (Veitch).—This elegantly-crested Fern has previously received a certificate and been described.

Anthurium Scherzerianum Wardi (Veitch).—Undoubtedly the best variety in cultivation of a well-known and handsome plant, some of the spathe being nearly 7 in. in length, and over 5 in. in breadth. It is named in compliment to Mr. Ward, gardener to the late Mr. F. Wilkins, Leyton, and was recently acquired by Messrs. Veitch & Sons at a cost of nearly £80.

Alsophila pycnoarpa (Veitch).—Previously certificated and described.

Pultenæa rosea (Rollisson).—A pretty, rosy-flowered, Australian shrub, previously certificated and described.

Dendrobium barbatulum grandiflorum (Sir T. Lawrence) was awarded a second-class certificate.—This is a large-flowered form of the plant grown in some gardens under the name of *D. Fytchianum*; it bears from ten to twenty white flowers on a slender raceme produced from near the apex of the leafless pseudo-bulbs. The individual flowers measure from 1½ in. to 2 in. across, and are pure white, or in some cases very faintly tinged with rose or lilac. Well worth culture.

Miscellaneous Plants.—Messrs. Veitch & Sons, Chelsea, contributed a choice group of new and rare Orchids, among which we noted several species not previously exhibited. *Epidendrum Wallisi* is a graceful-habited plant, its slender stems being about 18 in. in height, and clothed with distichous, grassy leaves; the flower in this case was solitary and terminal, and about 1½ in. in diameter, the sepals and petals being golden-yellow, the lip broadly fan-shaped and lobed, whitish, streaked with purplish-brown. *Sarcantus Fitzgeraldii*, to which a botanical commendation was awarded, is another pretty little Australian plant, where it is said to grow in very moist positions, and has distichous leaves from 3 in. to 6 in. in length, from which arise a spike bearing six or eight pure white flowers nearly 1 in. across, of circular outline, the base of the segments being dotted with rose. Several varieties of the golden-lipped *Oncidium varicosum* were much admired; as was also a well-bloomed plant of *Vanda cristata*, the flowers of which are of a grass-green colour, the saccate, trilobed lip being white streaked with blackish purple. *Odontoglossum*s were represented by several varieties of *O. Cervantesi* and *O. Roezli*, and its white variety; the same firm likewise sent *Acrides suavisimum*, *Vanda coerulescens*, *Masdevallia Lindenii*, *Lycaste alba*, *Cypripedium Druryi*, *Angraecum sesquipedale*, *Dendrobium Wardianum*, and others. A fine plant of the deliciously fragrant *Cattleya citrina* bore six or eight flowers. Among hybrid Orchids in this group were *Cypripedium seligerum*, *C. vexillarium* (one of the most distinct in the whole section), *C. Marshallianum* and *tesselatum*, the two latter bearing two-flowered spikes. A group of remarkably large and richly coloured seedling *Gloxinias* from Messrs. Veitch contained some distinct and very effective kinds, one of the best being Mr. Gladstone, a dense, rosy-crimson variety, with a clear creamy-white throat; *Excelsior* is another crimson variety, having a densely speckled throat; and *Prince Arthur* a good purple. All these varieties are remarkable for size, substance, and vivid colouring. Messrs. Veitch also showed a group of new *Crotone*s, the varieties being *Earl of Derby*, tortile, *Disraeli*, *M'Arthurium*, variable, and *Yongei*, all well grown and vivid in colour. A splendid plant of the scarlet-spathed *Anthurium Scherzerianum Wardi* bearing ten enormous bracts was very attractive. *Panax laciniatus* received a botanical commendation. A fine example of the Californian Pitcher-plant (*Darlingtonia californica*) bearing pitchers 15 in. or more in length, and a flower-stem nearly 2 ft. in height, came from Lady Dorothy Neville, Dangstein, and was awarded a cultural certificate. Mr. John Wills sent a tastefully-arranged group of Orchids, Palms, Ferns, and other decorative plants (plunged in a bed of blue Forget-me-nots), *Isolepis gracilis*, *Spinea japonica*, and the scarlet-spathed *Anthurium Scherzerianum*. Some well-grown *Cardodoxias* in this group were arranged with excellent effect. Messrs. Rollisson & Sons exhibited a miscellaneous group of Heaths, spring flowers, succulents, and Orchids, all in admirable condition; conspicuous in this group was a large-flowered form of *Phalenopsis amabilis*, the petals of which are very circular and perfect; the new rosy *Pultenæa* in the same group was also very effective. Mr. B. S. Williams, Holloway, furnished a couple of well-grown pyramid specimens of *Azalea amena*, and also a large and well-bloomed example of *Imantophyllum miniatum*. Messrs. F. & A. Smith, Dulwich, sent cut blooms of *Cinerarias* bright in colour; also plants of *Ficus elastica*, very faintly variegated with light or olive-green tints on a dark green ground. In the same group was a vigorous plant of a fine form of the orange-flowered *Imantophyllum miniatum*, named *Dulwich Beauty*, but which has long been known on the Continent as *I. miniatum splendens*. A large and well-flowered group of forced *Rhododendrons* came from Messrs. H. Lane & Sons, Berkhamsted, the most conspicuous sorts being *R. maculatum grandiflorum*, carmine, dotted with black; *Nero*, blackish purple; *limbatum*, fiery rose and white; *Etandard de Flandres*, lilac spotted with brown; *Empress Eugenie*, pale lilac; *Auguste Van Geert*, crimson purple; *Towardi*, rosy-lilac, very good truss; *Purity*, white; *Prince Camille de Rohan*, rosy-white spotted with brown, elegantly frilled petals; and *Ne Plus Ultra*, a rich violet-purple: with these also came a stand of cut *Roses*, consisting of *Tea* scented and other kinds. Mr. H. J. Elwes contributed a six-flowered truss of the large-flowered creamy-white *Rhododendron Nuttalli*, the individual blooms of which are nearly 5 in. in diameter, and delicately fragrant. Mr. W. H. Michaels, Cholmeley Park, sent a fine variety of the rather rare *Odontoglossum Andersonianum*, bearing two spikes, on one of which we counted thirteen richly-spotted lilac flowers. A very delicate lilac-tinted form of *O. Alexandræ* also came from the same exhibitor.

A small but remarkably well-grown group of Orchids came from Mr. J. G. Hepburn, among which we noted two well-bloomed plants of *Dendrobium infundibulum*, and a well-flowered example of *Dendrobium lituiflorum*, bearing two densely-flowered pseudo bulbs; a small specimen of *Arpophyllum giganteum*, which bore five spikes of rosy, shell-like flowers closely packed in cylindrical spikes; a good plant of *Cattleya citrina* bore three large and massive flowers; but the gem of the whole group was a plant of *Odontoglossum Roezli* bearing nine or ten flower-spikes, on which eleven flowers were fully expanded. Mr. W. Terry, Peterborough House, Fulham, contributed a well-grown group of Orchids, in which we noticed the old *Brassavola nodosa*, a richly-coloured form of *Oncidium sarcodes*, *Phalenopsis grandiflora*, *P. Schilleriana*, and a small-flowering plant of the purple *Cattleya Skinneri*. A small-flowering specimen of *Wigandia caracasana* came from the Society's garden at Chiswick; its blossoms are borne in a terminal panicle, and are of a lilac-purple colour, each being about 1 in. in diameter. Mr. Green, Holmesdale Road Nursery, Reigate, sent the elegantly-cut, grassy-leaved *Psemanthes dissectus elegans*, a most graceful decorative plant, said to be the result of a cross between *P. pinnatus* and *Sonchus arboreus*. Mr. G. F. Wilson showed a small-blooming specimen of *Cucumis himalayensis* with slender scandent stems, bright green, heart-shaped, notched leaves, and large, golden-yellow flowers 3 in. across. Mr. R. Clarke, Twickenham, sent three seedling forms of *Cyclamen*, one named *Brilliant* having small but vivid ruby-tinted flowers. Mr. H. Bennet, Manor Farm Nursery, Stapleford, exhibited a new English *Rose*, named *Mabel Morrison*, said to be a sport from *Baroness Rothschild*; it is an elegantly-cupped variety with well-formed shell-like petals; the colour is white delicately flushed with faint salmon-flesh; it is a decorative variety, and one which the committee desired to see again. From the same exhibitor came a fine batch of the *Rose Duchesse de Vallambrosa*, which was certificated at the last meeting. Mr. R. Dean sent a large and varied group of Primroses and laced *Alpine Auriculas*; among distinct kinds we noted *Primula denticulata*, *P. purpurea*, and the snow-white *P. nivalis*; the delicate blue *Aemone apennina*, and the scarlet *A. fulgens* were also represented by well-grown plants. From Messrs. J. Standish & Co., Ascot, came a tastefully-arranged group of Ferns and flowering plants, among them well-grown specimens of *Adiantum gracillimum*, the new *Filiferia Palm* (*Pritchardia filifera*), small plants of the coral-flowered *Echmea miniata splendens*, well grown *Lily of the Valley*, and *Azaleas*, one of the most conspicuous of which was the double-flowered *A. Borsig*, a kind with flowers of a very whiteness. A seedling *Myosotis*, named *Beatrice*, was shown by Mr. Groves, Shortlands, Kent; it has large, clear blue flowers, ½ in. in diameter, and the committee desired to see it again. A well-grown plant of *Anthurium Scherzerianum album* came from Messrs. Veitch & Sons, together with cut specimens of the *Luga pulcherrima*, bearing vivid crimson tassel-like flowers in dense clusters, hanging gracefully from the axils of the finely-cut leaves.

Fruits and Vegetables.—Exhibits under this head were limited. Mr. W. Rapley, gardener to R. Hudson, Esq., Clapham Common, contributed a brace of Cucumbers named *Osmaston Manor*; they were considerably over 2 ft. in length, and remarkably fresh and handsome in appearance. Mr. James Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton, sent some well-grown Mushrooms. Mr. H. F. Jones, The Gardens, Bentley Priory, Stanmore, furnished white and purple-topped varieties of *Scakale*.

NOTES AND QUESTIONS—VARIOUS.

Forsythias in the Landscape.—Although these valuable shrubs are not showy when seen close at hand, they are visible and even telling for long distances; therefore they are well fitted for the banks of lakes and like positions, where they may be seen from a distance: their hardiness and free-flowering qualities make them most valuable.

Clivias for Conservatory Decoration.—*Clivias* will be found to be very useful for indoor winter decoration, their Lily-like, orange and cinnamon-coloured flowers being produced from October to May. They are best grown in small pots—say 6-in. to 8-in. ones—as the flowers can then be seen to better advantage than in the case of large specimens. They succeed best in a light, airy house where they can have plenty of water, when, if grown in good fibrous loam, they are little inferior as regards effect to *Vallota purpurea*.—S.

Birch Wine.—I have read with both profit and pleasure the notes on the "Plant-lore of Shakespeare," contributed to THE GARDEN by "H. N. E." who I am sure will excuse me for pointing out that although beer is now seldom made from Birchen twigs, yet it is by no means an uncommon practice in some country districts to tap the white trunks of Birches, and collect the sweet sap which exudes from them for wine-making purposes. In some parts of Leicestershire this sap is collected in large quantities every spring, and Birch wine, when well made, is a wholesome and by no means an unpleasant beverage.—B.

Fruit Prospects in Suffolk.—Apricots have got severely browned; under glass copings, however, and also under a few overhanging boughs, the germs are yet safe. Peaches are in full flower and look strong and well. Pears on pyramids are generally full of blossoms, though some of the taller standards are thin; the forward blossom-buds are much browned by frost and pecked by birds. Apples are fairly well budded. Plums and Cherries are full of buds. Gooseberries look well, and are now showing fruit. Currants and Raspberries set abnormally late. Strawberries have suffered much from the constant rains, and many of the plants have a somewhat debilitated appearance.—D. T. F.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

HARDY CACTI.

I AM glad to find attention directed to this subject (see page 275). Nearly three years ago, in Dr. W. A. Bell's garden at Manitou, Colorado, I saw a collection of eight or ten species of hardy Cacti, which had been found in the neighbourhood, and which were grouped together on a bit of rough rockwork. A finer display I have seldom seen of all shades of yellow, crimson, and scarlet, than these presented, and I cannot but think that the Colorado Cacti would succeed perfectly in England. They are undoubtedly hardy, as I have seen the thermometer at Manitou, seventy miles south of Denver, go down to 22° below zero (Fahrenheit), and in parts of the State where *Opuntia Rafinesquii* grows freely, the snow sometimes lies for two or three months. The moisture and want of actual sunlight of our English climate would of course be somewhat against them, as in Colorado the sun is powerful even in winter, and is seldom obscured by clouds or mist for more than five or six days from November to April; the atmosphere, too, is extraordinarily dry. As, however, *O. Rafinesquii* succeeds in England, I can see no reason why other kinds of Cacti growing in their native country under exactly similar circumstances should not thrive equally well with us. Professor Porter and Mr. Coulter, in their "Synopsis of the Flora of Colorado," mention the following kinds of Cactaceæ, viz., *Echinocactus Simpsoni* (figured in THE GARDEN last week), *Mammillaria Nuttalli* var. *caespitosa*, *M. vivipara* (this latter species grows freely over the plains and foothills east of the Rocky Mountains, round Colorado Springs, and has been, I believe, successfully cultivated in England); *Cereus viridiflorus*, yellow; *C. Fendleri*, flowers deep purple and fruit edible; *C. gonacanthus*, scarlet, open day and night; *C. phoeniceus*; *C. conoides*; *C. paucispinus*; *Opuntia Cananachia*; *O. arborescens*; *O. Rafinesquii*; and *O. missouriensis*, which Mr. Hemsley mentions as growing as far west as Wisconsin and Kentucky, spread over the plains of Kansas and Colorado to the Rocky Mountains, and their brilliant blossoms are among the most striking ornaments of that land of flowers. All the above have been described or verified by Dr. Engelmann, of St. Louis, but the Cactaceæ of Colorado had been by no means thoroughly worked out when Professor Porter's "Synopsis" was published three years ago, and I do not doubt that by this time many additional species have been added to the list which I have just given.

Bugleet.

ROSE G. KINGSLEY.

My experience of Cacti as hardy subjects has not been very favourable, but *Opuntia vulgaris*, *O. Rafinesquii*, and *O. missouriensis* I have found to be quite capable of thriving out-of-doors all the year round. I have seen *Echinocereus phoeniceus*, and *E. viridiflorus* also stand the winter outside at Ghent; all the *Echinocereuses* are nearly hardy, and so are *Mammillaria decipiens* and *M. retula*; most of the *Echinopsis* are almost hardy. I have often exposed *E. Eyriesii*, *E. Zuccariniana*, and *E. multiplex*, but they die, although they grow first-rate in the open ground in summer. Kept dry under glass this winter I have kept, without any fire-heat, *Echinocactus*, *Echinopsis*, and *Mammillarias*; but *Opuntias* and *Cereus*, with the exception of those just mentioned, do not succeed in a temperature below 54°. The valley of the Thames is not favourable for testing not only the hardiness of Cacti but also that of other plants, for I find that many Alpine plants that winter well out-of-doors at Reigate die here. On sandy soils in the south and west I have no doubt many Cacti would thrive out-of-doors, and, as they can be got for a trifle, I should advise cultivators so situated to try them. It is the moisture, and not the cold, which kills them, and I have lost quantities of the hardy *Sempervivum* this winter from the same cause; they die off, although on walls and rockwork they are quite hardy.—J. CROUCHER.

— Allow me to bear witness to the extreme hardiness of *Cereus phoeniceus* and *C. viridiflorus*; also to that of *Opuntia humilis* and *brachyantha*. I have seen *O. Engelmanni* at Vienna, where it is said to be hardy, but I cannot speak from my own experience in that respect. It is your wet English climate, not the frost, which kills these singular plants, which are, nevertheless, well worth a trial on sunny rockwork.—MAX LEICHLIN, *Baden-Baden.*

NOTES OF THE WEEK.

CLIANTHUS CARNEUS.—Of this interesting and beautiful conservatory climber we have a plant trained up a pillar, now in full bloom, and it is greatly admired on account of the showy colour and singular form of its flowers. They are produced in drooping clusters, each blossom resembling a parrot's beak in form, and pale red in colour. This *Clianthus* grows freely in common garden soil; but it must be frequently syringed, as it is very liable to the attacks of red spider.—A NORTHERN GARDENER.

HYBRID AND SEEDLING NARCISSI.—Several large beds of new seedling Daffodils and other Narcissi are now very effective in Messrs. Barr & Sagden's bulb grounds at Tooting. Among them are some singularly interesting forms. They appear to be seedlings and hybrids between *N. poeticus*, *N. incomparabilis*, *N. Pseudo-Narcissus*, and *N. montanus*, and among them are intermediates which completely break down all the existing systems of classification proposed by different authors in grouping these useful early-flowering plants.—B.

GLOXINIAS AT CHELSEA.—The Gloxinia-house at Chelsea is just now well worth inspection, containing, as it does, hundreds of plants in the most healthy condition, laden with large and magnificently-coloured blossoms. Among them may be found many new seedling varieties, the flowers of which measure from 3 in. to 4 in. across, and possess most beautiful shades of colour. The plants themselves are mostly grown in 6-in. pots, which are completely hidden by healthy green leaves of unusually large size. A house from 50 ft. to 60 ft. in length full of such plants as these, each bearing from thirty to fifty flowers and buds, is indeed a sight worth seeing.—S.

CYMBIDIUM EBURNEUM.—A fine plant of this well-known but somewhat rare Orchid is now flowering freely in Lord Loudesborough's collection at Norbiton. It is furnished with from fifteen to twenty buds and flowers, the latter being of large size and of ivory whiteness. Few flowers are more chaste or beautiful than these, a circumstance which makes the comparative scarcity of the plant all the more to be regretted. Associated with it is the smaller-flowered but beautifully-marked *Cymbidium Dayanum*, which is also in bloom. W.

MIGNONETTE FOR MARKET.—Where the large quantities of Mignonette, both in pots and in a cut state, now to be seen in Covent Garden come from is no mystery after one pays a visit to Mr. Reeves' and Mr. Pliuley's nurseries at Acton. In the latter place, Mignonette is grown chiefly for cutting and a few bunches of good heads often realize at this time of the year almost as much as a van-load of plants in pots. For this purpose the plants are grown in 7-in. pots, placed closely together in frames, and allowed to grow at will, receiving abundance of air, light, and water. For spring blooming the seed is sown in autumn, and for the summer supply, in spring. Mr. Reeves grows his Mignonette chiefly in pots; he has at the present time long ranges of cold pits entirely occupied by it—in all 1750 dozen 6-in. pots filled with Mignonette for market.—S.

ALLIUM NEAPOLITANUM.—The flowers of this are now being imported in large quantities to Covent Garden Market from the shores of the Mediterranean. Unlike other *Alliums*, this one possesses no unpleasant odour, and its flowers are pure white, and produced in trusses like those of a small *Narcissus*, which they resemble. They are of great value for bouquet-making and for other decorative purposes. In England this plant rarely flowers before May or June, but if strong roots of it were divided in autumn, potted in good soil, and placed under glass, where they could be gradually brought forward, there is no reason why good flowering plants of it should not be obtained in March and April, or even earlier, for conservatory or greenhouse decoration, a purpose for which they would be found useful as well as for supplying cut blooms.—C.

BERBERIS DARWINI.—Mr. Hobday has done good service in calling attention (see p. 282) to this beautiful hardy, early-flowering shrub. I have not seen it growing against a wall, but we have several plants of it in the form of bushes, and at present they are objects of general admiration, each branch being thickly furnished with small golden flowers. Four or five weeks have elapsed since we began cutting flowers from one large bush of this Berberry, and it will not be out of bloom for another month yet; a long succession of flowers can therefore be had from one plant. Wherever two varieties of hardy-flowering shrubs are planted, this should certainly be one of them.—A NORTHERN GARDENER.

ANTHURUM SCHERZERIANUM FOR MARKET.—Considering the ease with which this plant may be cultivated, and the rapid manner in which it is capable of being propagated, it is surprising that it has not before now become a favourite with florists who grow plants for market. In the Pine-apple nursery there are several hundred large

plants of it which have been flowering freely all through the winter, and which are now and will be for months to come masses of waxy, scarlet blossoms. Few flowers are more effective when used in large bouquets or vases than those of *Anthurium*, and certainly there are none that will last in good condition in a cut state so long, and as they are produced by strong plants at nearly every season of the year, growers for market might do well to turn their attention in that direction.—C. S.

LACHENALIAS AS BASKET PLANTS.—We have just seen some large semi-circular baskets filled with *L. tricolor*, which, used in this way, is remarkably effective. These were grown by Mr. Ollerhead, Wimbledon House, and form masses of glossy leaves and orange-red spikes, nearly 18 in. in diameter. Grown in this way these beautiful greenhouse bulbs are highly deserving of careful culture.—B.

DENDROCHILUM GLUMACEUM.—For several weeks past I have had a plant of this Orchid in bloom; it is furnished with some sixty long pendent spikes of small white, thickly-set blossoms, which load the air with sweet Hawthorn-like perfume. Though not attractive as regards colour, this Orchid has, nevertheless, a graceful and pleasing appearance, and deserves to be more frequently met with in private collections than it is.—H. C.

TILLANDSIA LINDENI.—This plant is now flowering freely in Messrs. Veitch's nursery at Chelsea. Its flower-spikes are from 15 in. to 18 in. in length, and each of them bears from three to five fully expanded, rich blue blossoms, which are large in size and remarkably effective. Plants like this, which continue to open their flowers for weeks in succession, deserve more attention than they receive.—W.

DENDROBIUM BONALLI.—Several plants of this Dendrobe may now be seen in flower in Messrs. Rollisson's nursery at Tooting; on a stem of one of them there are thirty-five large blossoms, the golden-yellow throats and delicate violet-tinted petals of which are strikingly effective.—S.

WISTARIA SINENSIS AS AN INDOOR CLIMBER.—It is not often that one sees this plant growing indoors; nevertheless it is worthy of a place there, if a great variety of climbers be grown. We have a plant of it at present in full bloom on the roof of the conservatory, where its great clusters of pale blue flowers are very attractive, and they are also useful in a cut state. It will grow in any kind of soil, is not subject to insects, bears any amount of cutting without injury, and does not produce a mass of foliage to shade other plants underneath it.—A NORTHERN GARDENER.

STATICE HOLFORDI FOR MARKET.—Mr. Henry Bailey, Feltham, cultivates this plant largely for market purposes. It is grown in 6-in. and 8-in. pots, which are completely hidden by large healthy green leaves; the flowers, which are freely produced, are of a bright blue colour, and admirably adapted for bouquet-making. As a conservatory plant in small pots this *Statice* deserves more attention than it at present receives in private establishments.—S.

ORCHIDS IN CONSERVATORIES.—Much of the beauty of many Orchids when in flower is lost by their being kept in the warm, moist atmosphere in which they are usually grown, whereas, if removed to a cool conservatory they would be quite at home, and would last double or treble the time that they would in a warmer temperature. In the conservatory at the Pine-apple Nursery may now be found well-flowered plants of *Dendrobium Wardianum*, *D. nobile*, *D. thyrsiflorum*, *Odontoglossum Alexandræ*, and *O. Cervantesi*, all of which have been in bloom for many weeks past, and will in all probability continue in that condition for some time yet to come. The colours of the flowers, too, are much brighter when subjected to a cool, airy temperature than when kept in a hot, close one, and they are, moreover, much more interesting when associated with ornamental plants of other kinds than when seen in a house by themselves.—C.

ROYAL HORTICULTURAL SOCIETY.—We are authorized to state that the Queen has intimated her intention to visit the exhibition of choice flowers to be held in the conservatory at South Kensington, on Wednesday, May 2, and that the flower show which was to have been held on the 1st will take place on that day.

SHOW OF COVENT GARDEN PRODUCE.—We are reminded that the exhibition of fruit and vegetables to be contributed by the growers and salesmen belonging to Covent Garden Market promises to be a most successful one. It is to be held on the 18th inst. at South Kensington, as already announced. Gold, silver, and bronze medals, with certificates of commendation, are to be awarded by the Society to the most meritorious groups of plants, window decorations, table decorations, bouquets, Fern-cases, fruits, vegetables, and salads. We would suggest that salesmen should exhibit collections of the important produce now so largely brought to the market.

TREE CARNATIONS FOR WINTER.

ALTHOUGH these may be had in bloom the whole year round, the winter months are those for which special provision should be made by striking annually successional batches of pipings from plants that have bloomed the previous winter; for young plants are more floriferous than old ones, and when required for purposes of decoration small pots are absolutely necessary. We usually put in two or three batches of cuttings in succession during March and April. They are prepared in the same way as ordinary Pink pipings, are inserted thickly in well-drained pans, and are treated the same as other occupants of the propagating pit. Under such circumstances they root rapidly, after which they are transferred to a warm house or pit, and gradually inured to more light and air, preparatory to being potted off into 3-in. pots, the strongest singly, and the weakest two or three in a pot. The compost which we find suits them best is a moderately light turfy loam, free from wireworm, dry cow or sheep manure, and sharp grit or sand. They like a warm frame or pit until they have become well rooted, when they may be gradually hardened off in a cold frame by drawing the lights entirely off on fine days, and replacing them at night or during heavy rains. Before the roots get too much matted together, say in June or July, we shift them into their flowering pots, 6-in. or 7-in. pots being the size used for the strongest plants, and 4-in. or 5-in. ones for successional plants, using a compost similar to that above described, but in a rougher state. Plenty of drainage is of the utmost importance, and a sprinkling of soot over the potsherds acts both as a manure and a check to the inroads of worms. A good open position during summer on a bed of coal ashes suits them admirably, great care being taken to see that they do not suffer from lack or excess of root moisture. They should not be stopped but tied loosely to neat stakes as growth progresses. By the beginning of September those that were potted earliest will be coming into bloom, and they should be introduced to a light, airy house or pit, in which a temperature of about 55° can be maintained during the winter. Here they will produce blossoms in profusion, and for button-hole or other bouquets, or for intermixing with general floral decorations they are unsurpassed by those of even the choicest stove plants. Their colours range from the purest white to the brightest crimson, and amongst the intermediate shades may be found the softest and most delicate tints imaginable. They last, too, for a considerable length of time in a cut state, which is more than can be said of many flowers that are forced into bloom at the same period of the year. Green fly is sometimes troublesome, but fumigation or dipping soon clears them of it. The flower-pods of some varieties are apt to burst; such kinds should have a neat tie put round the flower before it is fully expanded. As soon as the blooms of Pinks become plentiful in spring and a stock of cuttings of these Carnations has been secured, the old plants may be thrown away or planted out in a spare border, where they will probably yield a few fine blooms late in the summer and autumn months. J. GROOM.

Henham.

Summer Treatment of Cyclamens.—Now that Cyclamens have for the most part ceased blooming, they should be placed in cold frames, where they can be partially shaded from sunshine during very hot weather. If the pots be set on ashes they will serve to keep them cool and moist, and occasional fumigation in order to keep them free from green fly and red spider must be resorted to. Abundance of air and moisture should be maintained about the plants, but too much water must not be given to the roots. Young bulbs of Cyclamens just raised from seed should be kept in a light moist and somewhat close atmosphere, protecting them from the fierceness of the sun by means of tiffany or mats, or if they can be placed in a naturally-shaded house or pit so much the better. Shift them on into larger pots as the roots touch the sides of those which they now occupy, until they are in 5-in. pots, which will be found large enough for the first year. Good sandy loam and a little leaf-mould or thoroughly decayed manure, constitute the best compost in which to pot them, and no manure-water should be given, pure and soft rain-water being more likely to induce satisfactory results. Bulbs of Cyclamens raised from seed sown in February, will make good flowering plants by Christmas or soon after if properly attended to.—S.

MAGNOLIA CITRIDORA.—A large tree of this *Magnolia*, growing in the Pine-apple Nursery, is now bearing nearly 3000 buds and blossoms; the latter differ from those of *M. conspicua* in being delicately streaked with purple as well as in other respects. They are also deliciously fragrant.—S

THE INDOOR GARDEN.

A USEFUL BASKET PLANT.

(*PELARGONIUM HEDEREFOLIUM* VAR. *KÖNIG ALBERT*).

NEARLY all the ordinary varieties of Ivy-leaved Pelargoniums are well adapted for hanging-baskets or brackets, but none surpasses in graceful beauty the new variety called König Albert, which, while fully as elegant in its growth as its congeners, has the additional merit of producing double blossoms, and these, like most other double flowers, last longer in beauty than the single-flowered types. The annexed engraving gives a good idea of the graceful contour of this Ivy-leaved Pelargonium as a basket plant when employed alone for that purpose, but it might also be grouped along with the scented-leaved varieties which are used with such excellent effect in the large hanging-baskets at the Crystal Palace, or even for fringing the margins of large baskets in which Dracaenas, Ferns, and other effective fine-foliaged plants are used. Pelargonium König Albert, which was figured and described in *THE GARDEN*, Vol. VIII. (1875), p. 81, bears clusters of double

Basket of Pelargonium König Albert.

pink flowers streaked with crimson. It was, we believe, the first double-flowered variety which occurred in the section to which it belongs. It was raised by M. Otto Leibmann, a Continental grower, and was imported and distributed by Mr. W. Bull. B.

HOW A COOL CONSERVATORY MAY BE KEPT GAY DURING WINTER.

It may interest some of your readers to know what may be done in the way of conservatory decoration during winter with little or no heat, and without the aid of a professional gardener. I have a small conservatory—13 ft. by 9 ft.—into which glass doors open from both drawing and dining rooms, and it is my ambition to keep it as gay and bright as possible at all times, but more especially during the dull, dark winter months. To supply this with plants in bloom I have another greenhouse or rather Vinery, 18 ft. by 10 ft., in which there is only a stove used merely to keep out frost. Here there is a small plant case heated with hot water by means of a common lamp, in which in early spring I raise seeds and cuttings. These, with a cold frame made of a couple of "curate's Vineries" slightly raised from the ground, are all the appliances at present within my reach. I am quite satisfied, however, from the experience of the last three winters during which the little conservatory has existed, that much more may be accomplished without heat

than is generally supposed. This has certainly been an exceptional winter: the stove in the Vinery has not once been lighted, and has to-day (April 14) been removed to its summer quarters. In consequence, no doubt of the mildness of the season, my plants have been more than usually successful with less trouble than in ordinary winters; but the care generally needed is more than compensated for by the pleasure of looking out of our sitting rooms at bright flowers and Ferns when out-of-doors all is dead and dreary. It is necessary, however, for the preservation of many of the plants which I grow, that some protection should be afforded in the bitter frosty weather, of which we here (in an Alpine climate, over 700 ft. above the sea-level) have generally our full share. Some thick, red curtains have done good service for this purpose. These our kitchen gardener (who is a valuable aid, though I keep the management of my flowers in my own hand) puts up every evening when the shutters are closed, and takes them down in the morning. These, with a few yards of frigidome, which he throws entirely over the stands at night, effectually keep out the frost. One is sometimes amused by the flowers being thus put to bed and tucked up, but it answers the purpose admirably, and ten minutes suffice for the performance of the operation. It is probable that an outside covering of frigidome might answer even better, and might be as easily arranged as is a sun-blind. This winter neither curtains nor frigidome have once been necessary, but many winters may pass before we have again so mild a season. Owing to absence from home and other unavoidable causes last year, the little house was not so gay as usual just at Christmas, but the year began with Roman Hyacinths and Narcissi, *Coronilla glauca*, both kinds of *Triteleia* (which are invaluable), and *Scilla bifolia* and *sibirica*. A few common Primroses dug up from the woods, potted, and arranged to peep through the hardy Ferns (of which I grow a good many), were also very effective. By the beginning of February I was able to add to these some lovely red Cyclamens and Primulas, with Mignonne and Czar Violets. The Primulas were backward, owing to the seed being unavoidably sown very late; for experience has taught me that to be successful with these in a cold-house it is necessary to have strong plants early in the autumn, when it is quite possible to have them in full beauty at Christmas. All through March, besides those already mentioned, there has been a succession of Narcissi, Hyacinths, dwarf Tulips, Neapolitan Violets, and Lachenalias. Several hardy plants have also been pressed into the service, such as *Iberis gibraltarica*, *Orobis vernus*, *Omphalodes verna*, *Polyanthus*, and *Primula denticulata*; of these, the three first-named are not so generally appreciated as they should be, and all are valuable. *Sparmannia africana* is an old-fashioned shrub, which has done very well here this winter, and *Oxalis cernua* is another bright little plant for a sunny corner. *Tropeolum Jarratti* will be a mass of flower in a day or two, and is as vigorous and healthy as possible, though grown entirely in a window. A small variegated Ivy has been charming amongst the green of the various Ferns; and some small *Laurustinus* bushes, which I had potted after reading the note about them in *THE GARDEN* some months ago, have been all that could be desired. I am aware that all the plants which I have named are quite common, and to be found in every warm greenhouse; not so, however, where the heating apparatus is comparatively ineffective or altogether wanting. It takes, on an average, 100 pots of Ferns and flowers to fill the little conservatory of which I have been speaking, and as I do not care to have dozens of one kind of plant, it taxes my powers considerably to keep it gay all the year round. I therefore glean with the greatest interest from all the notes which I find in the pages of *THE GARDEN* not only on half-hardy greenhouse, but herbaceous border plants. For this reason I venture to hope that my experience in blooming flowers with very little heat may prove of some use in helping others to make the most of the means within their reach.

Ashmore.

K. L. D.

Salvia Gesneræfolia.—Amongst plants that flower naturally at this season, few are more brilliant than this *Salvia*, which is rendered all the more conspicuous on account of white and yellow flowers being so abundant in early spring. It is a plant which is

most accommodating as to soil, and does not require heat after the cuttings are rooted. We usually propagate it in May and gradually harden the young plants off in a cold frame, shifting them according to the size of specimens required. We winter them in a cool Vinery, and at this season every shoot is crowned with brilliant blossoms. *Salvias* are undisturbed by insect pests, and if attended to properly with water and other little details of culture, few plants are more easily managed.—J. Groom, *Hemlan.*

GLOXINIAS AND THEIR CULTURE.

THE present race of these beautiful Gesnerads owe their parentage to a few species imported from different parts of S. America; the hybrids of the present day, however, are superior to the species in every quality, in size, form, and the almost unlimited variety of colour, from the purest white, through the different shades of pink to deep red, and from pale blue to intense purple, with endless forms of spotting and banding with light and dark colours; in fact, there are few flowers that can boast so much variety: in addition to which they have many other points to recommend them. They are very easy to increase, either from seed or by cuttings; they are also easily grown, and most useful for decorating the stove or intermediate-house in the summer season, continuing to bloom more or less for a considerable period; while the flowers are very useful for cutting, and if placed in water they will last for several days, provided the plants have made their growth and produced their blooms in a thoroughly light situation, with the requisite amount of air to impart a sufficient substance to them, the latter an indispensable condition when they are required to be used in a cut state. The ability that the flowers of most stove plants possess to enable them to keep well when cut for vases, &c., generally depends materially upon the way the plants have been previously managed, but there are few so much dependent in this respect as are *Gloxinias*, as the whole character of the plant is so much changed for better or worse, according to the conditions of cultivation. When well grown the leaves are stout and short, borne on stout foot-stalks, with the flowers standing up well above the foliage; whereas, if grown either too moist or too hot, with insufficient light, the whole plant has a soft, flabby, straggling appearance that effectually destroys its beauty and shortens the duration of its blooming. By using a sufficient number of plants, and bringing them on at different times, a succession of flowers may be kept up from April until the end of September.

In raising *Gloxinias* from seed, it should be sown early in the spring, so as to allow the plants an opportunity of attaining a sufficient size, in order that they may flower during the summer in a way that will exhibit their true character: if sown about the middle of March, they will have the requisite time. The seed should be sown in an ordinary pan with 1 in. of drainage at the bottom, on which place a little *Sphagnum*; the soil should consist of equal parts of loam, peat, and leaf-soil, all sifted; add to the whole one-sixth its bulk of sand, it being essential to have the material of a loose open nature, or the roots of the young seedlings will be injured in transplanting them; fill the pan with the soil to within $\frac{1}{2}$ in. of the rim, pressing it down moderately firm, then water with a fine rose, so as to close up the surface, and on this sow the seeds, not too closely, or they will become crowded and consequently drawn up before they are large enough to pot off; cover very lightly, and place in a temperature of 65° . As soon as the young plants appear, elevate them close up to the light, screen from the midday sun, and supply them with water, giving a little air during the day. When the leaves are 1 in. long, move singly into 3-in. pots, using soil similar to that in which the seeds were sown, and at once replace them near the light, raising the temperature as the days increase in length. By the end of June they will require shifting into 4-in. pots, using the soil without sifting, and should receive the treatment previously recommended. The best kinds should be marked for propagation and the inferior ones discarded. When the flowering is over, give them less water, discontinue shading, and admit more air, so as to ripen the growth. When the leaves have died down, the soil must be allowed to become quite dry, and be kept for the winter in a temperature of 50° —cooler than this is not safe for any length of time. They

generally winter the best when the bulbs are allowed to remain in the soil and pots in which they have been grown; but as they become large and are in pots of a considerable size, this is not always convenient, in which case they should be stored in paper bags filled with dry sand to preserve them from the air, otherwise they shrivel, and thereby receive serious injury.

To give a succession of flowers through the summer a portion of the plants may be started about the middle of February, and a further supply in March; let the pots be proportionate to the size of the tubers—7 in. in diameter will be large enough for the second season. In potting just leave the crowns of the tubers on a level with the surface of the soil, and immediately they are potted place them in a temperature of 60° at night, and 5° or 10° warmer by day; if not, put in heat as soon as potted, the roots will rot; the soil ought to be in a slightly moist state when used, and little water should be given until growth has commenced. Treat them throughout the season as recommended for the preceding summer as to heat, shade, air, light, and moisture. As already pointed out, their satisfactory flowering will depend upon their receiving abundance of light; a shelf over a path within a few inches of the roof is the best place for them, for in such a situation not only do they get the requisite amount of light, but they also receive more air, both and being so essential to short sturdy growth. This summer they will bloom well, and increase considerably in the size of their roots, yet it is in the third and fourth years after sowing that they will make the finest display.

When the bulbs get large they may be divided, retaining to each portion some of the buds with which the crown is furnished; but the most general method of propagation, and by far the most expeditious, is by leaf-cuttings. If the leaves be taken off in the summer when fully matured with a portion of the leaf-stalks, and this portion inserted in 5-in. pots, drained and filled with half peat, or loam and sand, with $\frac{1}{2}$ in. of sand on the top, and kept in a brisk heat, slightly shaded, and the soil moist, they will form healthy bulbs before autumn; or, if the variety that is to be increased be scarce, several may be produced from single leaves by cutting through the midrib on the under side in four or five places, and laying the leaves flat down on the soil in pots or pans, prepared as above, but sufficiently wide to admit of their being so placed; over each place, where the midrib has been severed, secure the cut parts on the soil with a pebble about the size of a cockle, at which points bulbs will be formed, which, when the top has decayed in the autumn will require to be wintered, and afterwards grown on in every way as recommended for the plants raised from seed.

The following named varieties are all well worth growing:—

ERECT-FLOWERING KINDS.—*Alfred de Musset.*—Bright red striped with lilac. *Duke of Edinburgh.*—Tube white; throat deep violet shaded with maroon. *Panthère.*—Blue spotted with white: throat white and massive. *Scarlet Gem.*—White tube; throat spotted with lilac; limb deep scarlet. *James Brand.*—Throat creamy-yellow spotted with violet; lobes violet. *Don Luis of Portugal.*—White tube; throat spotted with carmine with a zone of violet; white limb. *Magenta Queen.*—Tube deep red; base of limb deep crimson edged with magenta. *Mr. Thomas Binney.*—Red throat; limb crimson. *The Czar.*—Tube white; limb purplish-violet. *A. Haut.*—Blue spotted on a white zone. *Byron.*—White, amaranth lobes. *Chateaubriand.*—White lobes; throat delicate rose.

PENDENT VARIETIES.—*Alice.*—Limb mauve; throat yellow. *Angeline.*—Tube rose barred with white. *Mogul.*—Tube spotted with red; crimson-purple limb. *M. Alphant.*—White tube; violet-spotted throat; purple limb. *Eblouissant.*—Bright red; throat white. *Delicata.*—Outside of tube white; inside violet; base of lobes rose margined with white. *Grand Monarch.*—Tube white; throat violet spotted with white; limb deep crimson. *Ne Plus Ultra.*—White with crimson throat spotted with carmine. *Bird of Paradise.*—Lilac; throat white spotted. *M. Grivet.*—Throat spotted with maroon, bordered with violet; mouth spotted with violet. *Mrs. William Bull.*—Red flaked with white. *Washington.*—Deep vermilion. *Wilhelmine.*—White, mouth banded with blue; throat spotted with rose.

INSECTS.—Gloxinias are not usually much troubled with insects. Thrips will sometimes attack the leaves, in which case sponging and fumigation are the best remedies. If aphides make their appearance on the young flower-stalks, they can best be destroyed by fumigation.

T. BAINES.

ACANTHUS LATIFOLIUS AS A WINDOW PLANT.

In the window of the bureau of the restaurant at No. 71, Avenue des Champs Elysées, Paris, I have throughout the winter and spring admired the beauty of a specimen of this plant. I enclose a sketch which gives a slight notion of its aspect, but nothing could do justice to its superb health and the deep, untiring gloss of its fine leaves. THE GARDEN has lately figured a specimen of the same plant as it grows in the open air. It is the most valuable of large-leaved room plants, and far more precious for general purposes than the long popular *Ficus elastica*, because it is quite hardy and very easy of culture.

Acanthus latifolius in window in Paris.

Therefore it will be found perfectly at home in cool rooms, halls, passages, &c., where little artificial heat is applied. The plant figured grows in a wooden box in the window. V.

PROPAGATING ALTERNANTHERAS.

WHERE *Alternantheras* are used in large quantities (and if they are to be used effectively a considerable number must be provided) then economical propagation becomes in many places a matter of some importance. I have tried various schemes with the view of saving labour and economising space, and at the same time have the plants in good condition and colour when first put out, and this latter condition can only be secured by growing them in some house or pit in the full light and warmth of the sun. They will grow in boxes under the shade of Vines or other plants, but they will not colour well unless exposed to strong light, and when green or badly-coloured plants are used in the first instance, half the season is wasted before they become really effective. I believe the best and quickest way of producing this class of plants in large quantities is to make up a special hotbed for them about the end of March or beginning of April. The pit, if a pit be used, should be filled up within 6 in. of the glass with leaves and manure or any other materials that will produce a steady bottom-heat of 80° or 85°, and that will last for three weeks or so at that point, and at this season this will be a very easy matter. When the heat has become regular and steady—which can easily be ascertained by placing a trial stick in the bed a foot or so deep, and examining it occasionally—about 4 in. or 5 in. of light, rich, sandy soil should be placed all over the surface, adding at the same time a sprinkling of silver sand on the top, and pressing it down moderately firm with a flat board. The cuttings may now be prepared and dibbled in 1 in. apart each way, and if kept close, moist, and shaded from bright sunshine, in a few days they will be forming roots, and as soon as that takes place, the shading should be discontinued and the ventilation gradually increased until they are finally hardened off and planted out. If carefully lifted and placed in trays or baskets with a *Rhubarb* leaf over them, they may be taken any distance and planted without flagging, and

with this advantage, that the plants being in good colour the beds are effective at once. We find April early enough for striking them, as it is not safe to plant them out here, even when thoroughly hardened, before June 10. *Iresines* and *Coleus* may be treated in exactly the same manner, only as the cuttings are larger, they should be allowed a little more space, and much better, dwarfier, sturdier, and better coloured plants are produced with a tenth part of the labour and trouble that growing them in small pots involves; and afterwards, with a little freshening up and renewing of the heating materials, I find the same pits come in very useful for late Melons.

E. HOBDAY.

Ramsay Abbey.

CULTURE OF COCKSCOMBS.

AMONG tender annuals grown for the decoration of greenhouses or conservatories, or even for sitting-room windows during July and August, none are more popular than the Cockscomb. It is generally considered difficult to manage, and it does require a little ingenuity to produce the fine combs which one occasionally sees on exhibition tables; but for ordinary purposes the treatment is simple enough. In order to secure fine healthy specimens, good seeds must be obtained. If it be two or three years old all the better, as in that case the plants have not such a tendency to produce coarse foliage, and the combs come finer. The seeds should be sown in March or April in well-drained pots filled with rich soil to within an inch of their rims; scatter the seeds evenly and thinly, and cover lightly with a little sand and fine soil. They will germinate best in a frame set on fermenting material in a temperature of 65° by night and 75° by day. As soon as the plants appear, they should be kept as near the glass as possible, to prevent them from being drawn, and as soon as they are ready to handle they should be potted singly, in pots 2½ in. or 3 in. in diameter. In potting, place them in the soil up to the seed leaves, and in order to preserve the roots from injury they should be carefully lifted. If it be not convenient to prick the plants off into small pots singly, they may be pricked off into pans or boxes 1½ in. apart, but whether they are in small pots, or in pans, they should be encouraged to grow as fast as possible, and not have too much water; for keeping them dry rather than wet will induce to them to produce combs; and as soon as those that are well shaped can be selected, the plants should be potted into 4-in. or 5-in. pots, giving them a little water a few hours previously. The best compost for Cockscombs is a rich loam, rather inclined to be light, pulled to pieces with the hand, not sifted; to three-fourths of loam add one-fourth of well-rotted cow-manure, or the same quantity of rotten botbed manure, and a good sprinkling of sharp sand, mixing the whole well together. In potting, the soil should be pressed rather firmly about the roots, but not so as to make the ball too solid, otherwise the water will pass freely away; and if it be too open, the danger is that the plants will run to much leaf. After potting they must be kept as near the glass as possible, and if they be plunged up to the rim in a hotbed, it would be the best position that could be afforded them. The final shift should be into 6-in. or 7-in. pots, according to the health and strength of the plants. If they be merely required for decorative purposes, the former will answer perfectly, but if required for exhibition they should have 7 in. or 8 in. pots. At the last potting good drainage must be secured, and the shifts must be given before the combs are too much developed. Under this treatment good combs will be produced, and the plants will be sure to be dwarf, and nearly uniform in size, a point of importance when they are required for exhibition.—R.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Double Chinese Primulas.—The plant of Marchioness of Exeter, shown at South Kensington on the 21st ult., was probably one of the finest of that strain of *Primulas* ever seen. Mr. Gilbert, who has several others nearly if not quite as good, asserts that he attributes their fine growth to using charcoal largely in the compost in which they are grown. Not only does this furnish good and necessary drainage, but it also affords valuable root food, and it is evident that the Chinese *Primula* has a special fondness for it. Those who are accustomed to grow old plants of the Chinese *Primula* are well aware of the extreme difficulty experienced in getting them safely through the winter on account of their tendency to damp off. Evidently Mr. Gilbert finds in the free use of charcoal a remedy for this defect.—A. D.

Fuchsias in Baskets.—Now is a good time to put young plants of *Fuchsias* into baskets, in order to obtain a good display late in summer and throughout the autumn. Varieties of slender habit are best adapted for the purpose, and if the shoots be kept persistently stopped, the plants will form dense bushes, which will cover the bottoms and sides of the baskets, and, when suspended from the roof of a greenhouse or conservatory laden with bloom, will form striking objects. The flowers, indeed, are shown off to greater advantage in this way than when the plants are grown in pots and trained in a pyramidal section. Good rich loam, plenty of water, and timely attention to stopping the shoots so as to obtain a dense pendulous habit at first, are all the plants require to bring them to a high state of perfection.—S.

THE LIBRARY.

THE MINIATURE FRUIT GARDEN.*

WHEN a book on fruit culture or indeed on any other branch of gardening industry has reached an eighteenth edition, little need be said as to the value or otherwise of its contents; nevertheless, the advent of the present edition is worth noting as a sign of the increasing interest that is being taken in one of the most important of all the branches of economic gardening, and one, moreover, which ought to be as great a source of wealth to ourselves as it undoubtedly is to our French, Belgian, and American neighbours. Apart from the question of soils, aspects, different methods of fruit-tree protection, and other kindred subjects, this little volume contains a good deal of useful information on the different stocks best suited to the requirements of different varieties of hardy fruits, and the remarks on "double grafting" are alike instructive and interesting. The lists of fruits for the different modes of culture are not overburdened with varieties, only the best and most profitable being named; and, as these selections are made with reference to keeping up a succession of fruits for dessert or culinary uses, they will be of great value to amateurs and others who may from time to time refer to them. Records of modern improvements in fruit culture, not elsewhere obtainable in so convenient a form, are also given. While upon the whole the work is perfectly trustworthy, we must not fail to point out one of a few inaccuracies into which Mr. Francis Rivers—the editor of the present edition—has been led by Mr. Bartley's paper read before the Society of Arts a short time ago. For example, at page 14 of the introduction we find it stated that we have only 40,000 acres of land in this country used as market gardens. Now these figures apply to land devoted to the culture of vegetables for market only, the total acreage of fruit grounds or orchards (apart from nurseries) being about 157,000 acres in addition. We are the more particular in pointing out this mistake, as extracts from the paper referred to have gone the round of the press without correction, although we explained how the error had arisen when the paper was read. The following extracts will show the kind of information which this little book contains as regards the improvement of hardy fruit trees and other matters relating to them.

Apples as Bushes on the Paradise Stock.

There are some varieties of Apples that do not form, even with care, well-shaped pyramids; such sorts may be cultivated as bushes when grafted on the Paradise stock, and are then excellently well adapted for small gardens. I have, indeed, reason to think that a great change may be brought about in suburban fruit culture by these bush trees. I have shown elsewhere how bush Pears on Quince stocks may be cultivated. Pears are, however, a luxury; Apples and Plums are necessities for the families of countless thousands living near London. Apple bushes, always very pretty and productive trees, may be planted 1 ft. apart row from row, and 4 ft. apart in the rows. If two or three years old when planted, they will begin to bear even the first season after planting. They should be kept from the attacks of the green aphid in summer by dressing the young shoots with Quassia mixture, and from the woolly aphid by Gishurst Compound. The principal feature in this culture is summer pinching, which must regularly be attended to, from early in June till the end of August; this is done by pinching or cutting off the end of every shoot as soon as it has made five or six leaves, leaving from three to four full-sized ones. Some varieties of the Apple have their leaves very thickly placed on the shoots; with them it is better not to count the leaves, but to leave the shoots from 3½ in. to 4 in. in length. If the soil be rich, and the trees inclined to grow too vigorously, they may be removed biennially, as recommended for bush Pears, by digging a circular trench 1 ft. from the stem of the tree, and then introducing the spade under its roots, heaving it up so as to detach them all from the soil, and then filling in the earth dug from the trench and treading it gently on to the roots. There is no mode of Apple culture more interesting than bush culture. I planted 100 trees in the spring of 1862. They bore a fine crop in 1863 of most beautiful fruit, and in 1864 gave a crop almost too abundant.

* "The Miniature Fruit Garden," by Thos. Rivers. Lond. pub. Longmans, Green, & Co., 1877.

Apples as Bushes for Market Gardens.

In a well-ordered fruit garden every kind of fruit should have its department, and instead of seeing, as in Kent, a row of trees of all sorts, mixed in the most heterogeneous manner, no mixture should be allowed; every kind should have its allotment—Apples on the Paradise and the Crab stocks, Pears on the Quince stock, the same on the Pear stock, Morella Cherries as pyramids on the Mahaleb stock—the best of all methods for their culture—and the various kinds of the Duke Cherries on the same kind of stock. Heart and Bigarreau Cherries on the common Cherry stock, Plums as bushes, pyramids, or half-standards, should all be separated, and not planted higgledy-piggledy, as they have been and are now. The sound-headed market gardener will, when his mind is turned to improve fruit-tree culture, see all this and make his fruit garden a pattern of order. I have been led into these remarks on market garden fruit-tree culture by my own experience, and especially into a consideration of the great improvement that may be made in the culture of Apples on the English Paradise stock. My plantation of Cox's Orange Pippin Apple trees on this stock in the season of 1861—the third year of their growth in their present quarters, and the fourth of their age—gave an average of a quarter of a peck from each tree, so that we might have from 4840 trees, growing on 1 acre of ground, 302 bushels of fine Apples worth 5s. per bushel, or £75. In 1866, the trees then averaging half-a-peck each, would double this sum, and make an acre of Apple trees a very agreeable and eligible investment. The kinds likely to sell best in the market, and which are most productive, are the following:—Cox's Orange Pippin, Ribston Pippin, Sturmer Pippin, Scarlet Nonpareil, and Dutch Mignonne; these are dessert Apples. The following are valuable kitchen Apples, and abundant bearers:—Hawthornden, New Hawthornden, Stirling Castle, Cox's Pomona, Keswick Codlin, Dumelow's Seedling or Wellington, Lord Suffield, Norfolk Beater, and Duchess of Oldenburgh. Such large varieties as Bedfordshire Foundling, Blenheim Orange, and Warner's King, should have more space, be planted 4 ft. apart, and be thinned out by removal to 8 ft. apart, as recommended for Pear trees. The proper method of planting and managing these bush Apple trees, is exactly that recommended for bush Pear trees on Quince stocks. It may be, by some, made a question of expense, for although the return must be large and profitable, the purchase of nearly 5000 Apple trees would involve a large outlay. To this I reply—first, that stocks, costing only a small sum per 1000, may be planted and grafted where the trees are to grow permanently; and secondly, that a large demand which my method of planting would create, will also create a cheap supply. The preparation of an acre of ground should be as follows:—It should, previous to planting, be forked over to the depth of 20 in. (if very poor and exhausted, from 30 to 40 tons of manure may be forked in)—not more—as trees such as I have recommended, viz., Pears on the Quince stock, and Apples on the English Paradise stock do not root deeply—this ought to cost £12. The annual expenses are, forking the surface in spring £1 6s. 8d., and hoeing the ground, say four times during the summer, £1 1s. I give the amounts paid here for such work. Then comes the summer pinching of the shoots by a light-fingered, active youth, and this may, at a guess, be put down at £1, making the aggregate annual expenses, £3 10s. 8d., or say, £1 per acre. The large return will amply afford this outlay, even adding, as we ought to do, the interest on capital and rent. It will be seen that what I propose is in reality a nursery orchard, which may be made to furnish fruit and trees for a considerable number of years. To fully comprehend this we must suppose a rood of ground planted, as I have described, with 1210 bush Apple trees. In the course of eight or ten years half of these, or 605, may be removed to a fresh plantation, in which they may be planted 6 ft. apart; they will at once occupy half an acre of ground. At the end of sixteen or eighteen years every alternate row of trees in the first plantation—the rood—will require to be removed, which will give 302 trees to be planted, 6 ft. apart, leaving 303 in the original rood. The 1210 trees will by this time occupy 1 acre of ground at 6 ft. apart. With proper summer pruning or pinching they will not require any further change, but continue to grow and bear fruit as long as they are properly cultivated. The great advantage reaped by the planter is the constant productiveness of his trees; from the second year after planting they will be always paying their way. The unjudicious fruit cultivator will quickly find out the great advantage of my mode of Apple and Pear cultivation. Still, it may be thought too serious a business to attend to 3000 or 4000 trees per acre, and only adapted to a very humble cultivator; I ought, therefore, to state that those who wish to cultivate Apples and Pears for market purposes may with a sound prospect of success, if the soil and climate be favourable, plant Apples on the English Paradise stock, and Pears on the Quince stock, either as pyramids or bushes, 1 ft. and 6 ft. apart, row from row, the former distance for dwarf,

prolific sorts, the latter for robust growers. This distance will admit of light crops of vegetables for 2 ft. in the centre between each row for several years, and till the trees—which must be under summer pinching—cover the ground. In the usual old-fashioned mode, Standard Apple trees are planted in orchards at 20 ft. apart, or 108 trees to the acre; if the soil be good and the trees properly planted, and the planter a healthy, middle-aged man, he may hope, at the end of his threescore and ten, to see his trees commence to bear, and may die with the reflection that he has left a valuable orchard as a legacy to his children, but has not had much enjoyment of it during his life. Now, although, like most fathers, I have a strong wish to benefit my children, I hold the idea that one ought also to think of one's own gratifications. Since writing the above, my attention has been directed to a plantation here; its Apple trees are grafted on the English Paradise, they are 4 ft. apart, and are safe for twenty or thirty years if pinched and pruned as directed. Plantations made at 4 ft. apart may in the course of a few years be brought to a permanent distance for pyramidal trees, that of 12 ft. apart; the trees originally planted being removed to another plantation. They may be safely moved at two or even three years after planting, the removal being performed as early in October as practicable.

Experiments in Making

Vine Borders.—When shifting some of our Vines here from the old to the new gardens, I tried an experiment with three plants of the Black Tripoli of same age and size, by planting them in a confined border of 4 ft. in width and 3 ft. in depth. The roots had to be coiled in the border, and the compost used consisted of tree leaves, horse-droppings, and manure from a Mushroom-bed, mixed with lumps of charcoal. The roots of the Vines were quite confined to the border, which was paved in the bottom but well drained, and in the growing season its surface was top-dressed with guano. During the first year the Vines produced a few small bunches, but the flavour of the Grapes when ripe was quite nauseous compared with what they would have been had they resembled that fine vinous-flavoured variety when grown in a proper border. During the second year's growth the crop was a good one, both bunches and berries being of a fair size; but the latter did not colour well, and their flavour, although sweet, was quite devoid of the vinous aroma for which the variety is celebrated. After the second year's growth the Vines were grubbed up and the experiment ended, for it showed that the soil may be made too rich for the growth of the Vine, and that the flavour of the Grapes is affected by the food upon which the roots feed. Amateurs and others not acquainted with the proper soil for Vine borders should therefore eschew all rich nitrogenous composts, and rest satisfied with the soils usually recommended for the growth of the Vine. The greatest success in Grape-growing is attained by having well-drained borders, in managing the Vines properly during the growing season by giving the roots stimulants in the shape of liquid manure, and in keeping the foliage clean and healthy.—WILLIAM TILLERY, *Welbeck*.

DASYLIRION LONGIFOLIUM.

This species has flowered in the open air at Hyères, in the south of France, and the "Revue Horticole" gives a figure of it which we now publish. The leaves attain a length of 5 ft., and the flowers, which are white, are very numerous. It is one of the many fine plants which the climate of the south of France permits the amateur to enjoy among his Roses and Acacias.

LATE GRAPES AND HOW TO PRODUCE THEM.

We have yet a good deal to learn on the subject of keeping Grapes after they are ripe, and it is a matter that is every year becoming more urgent, considering to what an extent the market is supplied by late Grapes, which have usually been long kept before they come there. There is no doubt about good samples of Lady Downes, Black Alicante, or Gros Colman still fetching high and remunerative prices to the grower, but good samples are the exception. As a rule the berries are shrivelled and little better than raisins—inferior in appearance, in fact, to foreign Grapes. Here and there may be found well preserved examples in private gardens, but success in keeping Grapes after they are ripe is not constant even with the best cultivators, and it may be safely asserted that the majority fail to keep their Grapes in good condition for any length of time

after they are cut from the Vines, while not a few fail to preserve them in good condition when hanging upon them. Yet we know that we possess good keeping varieties, and we know under what conditions they do keep in some cases; and the question which naturally arises is, Where do we err in our culture that we should not be more generally successful in that respect? Hitherto, I am afraid, too much stress has been laid upon the mode of keeping the fruit, and too little thought given to its preparatory culture. Something must, perhaps, be allowed for the difference of soils; but it can hardly be doubted that, if our general culture in other respects were more alike, so also would be our success in preserving the fruit. It is a certain fact in Grape culture that as the fruit is grown and ripened so will it keep. Grapes that are grown quickly or in a high temperature keep worst. Black Hamburgs ripened before May commonly shrivel before midsummer; when ripened by midsummer they keep well on into autumn; and when they are ripened in autumn, after a leisurely summer growth, they will sometimes keep till the month of February. Some may perhaps attribute the shrivelling of spring-ripened Grapes to the dry summer weather; but the same thing happens

Dasyliirion longifolium in flower at Hyères.

with Grapes ripened at the new year, or in January or February, when they should keep best. Grapes ripened at these seasons keep worse than those ripened in May, for the following reason: Early-ripened Grapes are like globules of water compared with Grapes ripened in August or September. The latter are solid-fleshed and firm, and have some staying power about them; but the former have none—they are nothing but skin and water, and they shrivel up into raisins almost as soon as they are ripe. I am presuming, of course, in the case of Grapes ripened during the natural season, that they have not been forced under a high temperature, for such treatment has the same effect, only in a less degree, as early forcing. It has been asserted by not a few good cultivators that late Grapes—such as the Muscat of Alexandria—require a high temperature to ripen them perfectly; but this is doubtful. There is nothing more certain than that Lady Downes and Black Alicante Grapes ripen, perfectly treated, like the Black Hamburg, only that they require

a little longer time; and this it is much better to give than to attempt to compress their period of growth within so many months, in order to have the fruit ripe before September is out. The best late Grape-grower with whom I am acquainted never has his fruit ripe before the end of October, and he has for nearly ten years kept his fruit in excellent condition till May or June. Two of his bunches, which were exhibited at South Kensington several years ago, received high commendation and a certificate, and the two bunches were afterwards sold to a Covent Garden fruiterer for £4. This was in May. In my own case, I am content if the fruit be ripe by the end of October—and it always keeps well.

I do not object to starting Vines tolerably early, say about the beginning of March; but it would not be with the object of having the fruit ripe early, but to give them more time. Moderate temperatures and slow growth always produce the best results, and these are perfectly-matured wood and fruit, as maturity ought to be reckoned, and which properly consists in the building up of the tissues slowly and solidly from the beginning. The idea that the keeping qualities of Grapes, or their general excellence, can be materially altered by lowering the temperature and giving more air when they begin to colour, probably after having been pushed on in a forcing atmosphere, is one of the most absurd ever entertained. Why should we ventilate freely at the finishing season more than at any other time? When the Vines are in active growth is the time to give air freely, to make the most of the sun's light and heat, and to maintain a moderate temperature in order that the tissues may be solidified and matured as growth progresses. If the growth of the plant, wood, and fruit be not perfected so far when the ripening begins, no after treatment can make up for that deficiency. If the wood be not short-jointed and firm, or if the berries be not fleshy, neither can be greatly changed for the better by giving more air and less moisture for a few weeks at the end, and consequently the chance of imparting keeping qualities to the Grapes is so far lost. My impression is that well-grown and matured examples of late Grapes ought to keep nearly as well as do the common white Almeria Grapes of the shops, but I cannot get either the Lady Downes or Alicante to keep anything like so long as these do. They are as plump at the end of eight or ten months as when they were gathered from the Vines, though the footstalks of the berries seem to wither at an early stage. A certain percentage of the berries rot, but they never shrivel, and they will lie for weeks exposed to the air without altering in the least. To the touch they are always quite firm, and they eat as crisp and fleshy as a bit of Rhubarb stalk. Yet the Almeria Grape is thin-skinned, and not like our keeping sorts. But the question is, what causes them to keep so well? Is it their perfect maturity, and can we grow our late Grapes to keep like them? I have tried to keep both Lady Downes and Alicante in the same way—that is, packed in cork dust—but have failed. The experiment was tried with only a few good bunches; but they were a mass of rottenness in less than a month, while those in the fruit-room in bottles were as sound as usual. It does not seem to be the mode of keeping them, therefore, wherein the secret lies, and I can only conclude that they keep because they are grown out-of-doors, and thoroughly matured in the proper sense of the term, and as it is here understood. Very probably, could we ripen late Grapes out-of-doors in this country, they too would keep as long and as well as the shop Grapes; but we cannot do that, and can only imitate the conditions as far as possible under glass, and these conditions are—a long season of growth, abundance of air (far more than is usually given), a moderate temperature, and a dry atmosphere. From March to the end of October would not be too long a season of growth, not supposing the leaves to fall till November. During the whole of that period air should be given freely both day and night, consistently with the maintenance of the necessary temperature, which need never exceed 80° at the warmest season. Shutting-up and steaming the house with moisture, as has been usually practised, I can never regard as anything else than an evil practice, for which no sensible reasons can be given, and which cannot be advocated on either theoretical or practical grounds. The Vines need water, and plenty of it, at the root, but to bathe their stems and leaves in vapour ten

or twelve hours out of the twenty-four is what they dislike. Such treatment produces soft, spongy wood, thin, flabby leaves, and fleshless berries; the first augurs badly for future crops, the second encourages mildew or insect plagues, and the last bodes ill for the preservation of the fruit. CHEF.

Strawberries.—Of some eight varieties of Strawberries under cultivation last season, viz., Carolina superba, President, Frogmore Late Pine, Amateur, Dr. Hogg, Wonderful, Black Prince, and Lucas—the last-named sort proved itself to be the best. President, which is generally a first-rate Strawberry, owing to the wet weather rotted in a semi-ripe state. Black Prince is grown for preserving, and Carolina superba on account of its fine flavour. Amateur and Frogmore Late Pine apparently require a warm situation, as their berries did not swell up properly. Lucas has very good properties that make it worth special notice. It is a full cropper, and the fruit is of good size; it will bear carriage better than such as President, and it has a deeper red colour than that variety. This spring, however, Lucas was inferior to both Carolina superba and President as a forcer.—ROBERT M'KELLAR, *Abney Hall, Chesham.*

Hybrid between an Orange and Citron.—M. Oudemans has, according to the "Popular Science Review" (April 1877), observed a fruit half Orange and half Citron. Externally it had precisely the form and colour of a Citron; internally four of the compartments presented the colour and taste of the flesh of a Citron; the other five had the qualities of that of an Orange. The formation of this fruit may be explained in two ways: the tree which produced it may have been a hybrid between *Citrus medica* and *C. Anrattim*; or the flower which produced the fruit may have belonged to one of the above species, and have been fecundated, at least partially, by pollen of the other. On the first supposition the case would be parallel to that of *Cytisus Adami*; on the second, which M. Oudemans regards as most probable, we should have a fresh instance of the influence of the pollen on the fruit. [It would be interesting to know for certain which plant produced this fruit, whether the Orange or the Citron, or whether the two kinds named were growing in proximity. It should also be borne in mind that *Cytisus Adami* is a graft hybrid. Similar vagaries have been repeatedly observed in Oranges, Apples, Pears, and Peaches.—Ed.]

Vine Borders at Lambton Castle.—Allow me to inform Mr. Simpson (see p. 272) that it is my intention to make known in due time the results of my Vine border experiments and send samples of the Grapes to the Fruit Committee at South Kensington. Up to the present time I have been under the impression that a Vine border made entirely of manure had not been put in practice. Mr. Simpson, however, asserts that my experiment is not the first of the kind that has been made, and directs us to the book on the Vine, p. 82, where there is a record of Mr. Thomson's experiments on old Vines, the roots of which had penetrated the subsoil; at 12 ft. from the front of the house, he is stated to have taken out a trench, carefully working inwards until the old border was taken out and the roots placed in new soil. This was done in June 1855, when there was a crop of Grapes on the Vines. In 1861, Mr. Thomson, being desirous to force somewhat briskly, had a pit in close proximity with the roots filled with fermenting manure and leaves, into which the Vines naturally rooted. This was repeated in 1862, after which the Vines were done away with. In my case, the Vines were struck from eyes in the spring, and planted out of 8-in. pots in 1873, no soil being used, except a little round the newly-planted balls; the rest was cow manure perfectly free from straw. The front of this border is new walled round, and in time I hope to prove whether a rich border is good or bad. There is, it will be seen, a great difference between assisting a soil border with heating material, and growing Vines altogether in the compost just alluded to. The borders at Cole Orton do not quite hold, to my thinking, a sufficient quantity of soil; a border 7 ft. wide and 18 in. deep is insufficient, as a rule, to produce heavy crops of Grapes. On Vines in such a border I have certainly seen excellent crops, but on clearing away the front of the border, a good many heels were found through which the roots had made their way into a well-managed kitchen garden.—J. HUNTER.

Espalier Apple Trees.—The most economical way of training Apple trees, as regards space is the much-neglected espalier. Nothing forms so neat a blind to the vegetable quarters from the walks as espalier-trained trees; and no other mode of training is in worse repute at the present time. The first expense of espaliers is of course considerable if iron be used in their construction, but wooden stakes will answer, and they can in most places be procured good enough for that purpose; wire espaliers are of course to be preferred, yet rather than not have espalier-trained trees, I would be content with the stakes. In selecting trees for espaliers choose those on a dwarfing stock which are naturally of a strong-growing habit.—R. P. B.

THE FLOWER GARDEN.

HARDY FLOWERS IN LONDON GARDENS.

SPRING-FLOWERING bulbs are now everywhere in full beauty, especially Siberian Squills, *Triteleias*, Anemones, and Grape Hyacinths, the latter being in best condition where they have been planted thinly on raised beds or in patches. The white-flowered form (*Muscari botryoides album*) may now be seen beautifully in bloom at Kew, where may also be found the Italian Squill (*Scilla italica*) producing spikes of bright blue

Twin-flowered Violet (*Viola biflora*).

flowers in abundance. The striped Squill-like *Puschkinia scilloides* is also just now in great beauty in several gardens round London. *Leucojum pulchellum*, too, growing in the form of large tufts, is bearing quantities of gracefully-drooping spikes of Snowdrop-like blossoms, and though more common, the Crown Imperials (*Fritillaria imperialis*) with their drooping, brightly-coloured flowers, must not be overlooked; one at Kew, named *F. imperialis fl.-pl.*, bears large whorls of blossoms on plants not more than 6 in. high; *F. glaucescens*, too, is now profusely laden with dark bell-shaped blooms. *Iris virescens* and *I. tuberosa* are likewise now in flower, as is also the common garden *Iris* in some warm spots. The Apennine Windflower (*Anemone apennina*) is just now very showy

Alpine Rock-cress (*Arabis alpina*).

on some rockwork in Mr. Ware's grounds at Tottenham; and the Poppy Anemone may be seen in abundance in nearly every London garden. The Roman Heron's-bill (*Erodium romanum*) is fast opening its small purplish flowers. Strong plants of *Pulmonaria virginica* are now in bloom, as are also various kinds of *Epimedium*. The White Primrose (*Primula nivea*) is yielding an abundant crop of flowers, as is also *Primula viscosa*, the blossoms of which are rosy-purple. In Messrs. Osborn's nursery at Fulham may be found *Pulmonaria grandiflora* well in bloom; also several varieties of *Corydalis*,

especially the white-flowered form (*C. albiflora*) and the large, yellow blossoms of *Doronicum caucasicum* and *D. austriacum* are likewise very showy. Associated with these is a little *Vinca* not commonly seen elsewhere, named *V. minor punicea*; it has small, well-formed, rich purple flowers, and when grown on stumps of trees or on rough stones it is very attractive. The Spring Bitter Vetch (*Orobus vernus*), too, is just now producing multitudes of purple and blue pea-shaped blossoms. Amongst *Narcissi*, *N. odoratus* and *N. juncifolius* may be mentioned as being at present in flower. *Tulipa Greigi*, at Mr. Ware's, is furnished with large orange-scarlet blossoms, which, owing to the weather being so sunless, are not so bright as they may be expected to be later in the season. The Wild Wood Tulip (*Tulipa sylvestris*) and the Common Hyacinth are flowering freely amongst stones and dead roots in the wilder parts of the garden. To these may be added *Scopolia orientalis*, *S. carniolica*, and several varieties of *Polyanthus*. Among the latter the best is one called Golden Prince, a kind which produces masses of

Common Heart's-ease (*Viola tricolor*).

Alpine Barren-wort (*Epimedium alpinum*).

large yellow blossoms in the greatest possible profusion: either for spring gardening or for ordinary border decoration this kind is well worth attention. S.

LILY BULBS.

I SEE that "F. W. B." (p. 268) professes to give a sketch of the specimens I sent you: to give correct sketches I could have had no objection whatever, but I do regret that he has not placed them before your readers as I placed them before you. At p. 260 I said, with regard to the smaller specimen—"On the right, as it is fixed on a card, you will see the remains of the inner scale; on the left is a portion of the new flower-stem; and between the two you will see the seed-bud distinctly about the size of a canary seed." Now "F. W. B." has not only reversed the specimen in his drawing, but he has made the seed-bud to sit in the very bosom of a scale double the size of the original, and made it to sit as if it were a part of and attached to that scale, whereas, in the original, it was easy to see that it was no nearer to the inner scale than it was to the flower-stem itself, and that it was distinctly separate from both. As a description, he adds—"(*n*) Axillary or seed-bud of Lily bulb as seen in January." I never took up anything like what he has represented in January. With regard to the larger specimens, I said—"In order to leave no room for doubt, I send you portions of three bulbs of the same kind which I lifted only three days ago. I have picked off the scales carefully until I arrived at the base of the flower-stem, where I knew I should find what was once the germ or seed-bud, but which has now grown so much since January last as to entitle it to be called a young bulb. About $\frac{1}{2}$ in. from the base of the new flower-stem you will observe a round scar which marks the seat of the old flower-stem before it had entirely died down. Opposite this scar, on the other side of the new flower-stem—and this is worthy of special observation—you will see in all the three cases that it is there where the young bulb is seated, thus showing that the true or legitimate seed-bud has a pre-determined or settled position in the parent bulb, namely on the opposite side of the old flower-stem, the new flower-stem being always between them." Instead, however, of making the sketch with the young bulb on the right of the new flower-stem, and the scar of the old flower-stem on the left, so as to illustrate my description, "F. W. B." has done the very reverse; he has drawn the young bulb in the very front of the

flower-stem, leaving out of sight the scar or position of the old flower-stem; and, moreover, he has drawn the figure of a scale where no scale existed, and made the young bulb to sit in this scale attached to it, contrary to anything seen in the original! In the three specimens sent, I picked off every scale to show that they had no connection whatever with the young bulbs; and you must have noticed that in picking them off I left no vestige whatever of a scar or wound at the base of the young bulbs, showing that the young bulbs had no connection with the scales. "F. W. B." says:—"It will be seen at a glance that it is nothing more than one of the axillary buds which exist at the base of each scale in nearly all Lily bulbs." The sketches, as given by him, may induce some of your readers to think so; but in the specimens which I sent there were certainly no such appearances. With reference to the production of the sketches, "F. W. B." says:—"As the editor of THE GARDEN has kindly allowed me to examine 'Dunedin's' specimens (referred to at p. 260), I have ventured to sketch those which most clearly show the gist of the matter, as far as respects the 'seed-bud.'" From this it would appear just possible that in making the sketches his memory may have misled him; but still I think, as a simple act of justice to me, he should have compared his sketches with the original specimens before he committed them to the press. On the same page I find another letter, which alludes to me, signed by "The Author of Notes on Lilies." From the contents of the letter in question I am led to believe that it is from Messrs. Teutschell & Co., the authors of a pamphlet on "Lilies and their Culture," published at Colchester in 1873. If so, any specific questions they may be pleased to put to me, I shall be happy to answer to the best of my ability. The only question in the present letter which seems to require any answer, is contained in the following passage:—"Since 1873 knowledge has advanced, and the question to which 'Dunedin' now offers a solution was asked by the same author in your pages (Oct. 23, 1875)—'Do Lily bulbs make fresh growth every year as does the Crocus?' I submit this question for future decision." 'Dunedin' did not reply." If in 1875 I appeared in any way uncourteous, I now sincerely apologise to Messrs. Teutschell. The question, however, would have been more complete if the writer or writers had stated in what way the Crocus does make fresh growth? I have never cultivated Crocuses, and have, therefore, never taken the trouble to inquire into their bulb development; but Loudon tells us that "the new bulb always forms above the old one." In another part of their letter the Messrs. Teutschell say:—"By the-by, 'Dunedin' did not begin his experiments to 'trace the progress of the seed-bud till October, 1873.'" By what means they arrive at this conclusion I am at a loss to understand; I may mention, however, for their satisfaction—if satisfaction it may be considered—that it is just forty years and six months since I planted my first Lily bulb; and that I have still in my garden, not an offset, but a *bona fide* successional bulb of that same original bulb. Some would be inclined, according to the mistaken idea, to call it the same bulb; but it is not so, and as it is now about 2 in. above the ground I call it, for the present, the last bulb of its race. DUNEDIN.

The mere fact of "F. W. B.'s" sketches being reversed cannot surely be of much importance, inasmuch as this must necessarily depend upon which half of a section is examined. We agree with the "Author of Notes on Lilies" (see p. 268), who suggests that "Dunedin" should prove his "seed-bud" theory by exhibiting specimens illustrative of it before the Scientific Committee of the Royal Horticultural Society at one of their forthcoming meetings. This will evidently be the most satisfactory way of settling this matter.—Ed.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Protection of Bulbs in Winter.—The beds containing Crocuses, Snow-drops, Dog's-tooth Violets, and Bulbocodiums, &c., in Mr. Ware's Nursery, at Tottenham, are covered up in winter with a few inches in thickness of horse-droppings free from litter. This has the effect of enriching the beds, protecting the bulbs from severe frosts, and in spring when the plants are in bloom it prevents the flowers from becoming splashed with soil during heavy rains. Cocoa-nut fibre would answer the same purpose, but it would not enrich the soil.—S.

Sedum acre elegans.—For covering bare stones on rockwork, or as an edging plant this *Sedum* is surpassed by few others; even during the dull winter months a good carpet of it has a bright and attractive appearance. It succeeds best when divided and transplanted in autumn, as it then gets well established in thick masses by the following spring, and is therefore better able than it otherwise would be to withstand the drought of summer.—C. S.

Spring Flowers and the Late Wet Winter.—The past winter has fully illustrated that excessive rainfall is more destructive to these than the most severe frosts which we ever experience, for not only are many spring flowers unusually late this year, but some of the hardiest amongst them are more cut up than after severe frosts. *Myosotis dissitiflora*, that was full of bloom at Christmas, is scarcely open yet, and has a starved appearance, the spring frosts having greatly crippled it after the mild weather and excessive downpour. Bulbs and Primroses are, however, apparently better adapted for such seasons, as these are everywhere beautifully in bloom.—J. GROOM, *Henham*.

PLATE LIX.

THE VIRGINIAN MEADOW BEAUTY.

(RHEXIA VIRGINICA).

Drawn by H. HYDE.

AMONGST Melastomads—a family characterized by their distinctly, triple-nerved leaves and square stems—it is quite exceptional to find a hardy plant, but in the genus *Rhexia* we have two species, both perfectly hardy, namely, the Virginian and Maryland Meadow Beauties, the former of which is well represented in the accompanying plate, and ought to be easily cultivated in every garden in which a bog bed is to be found. To many, however, this *Rhexia* will be as much a novelty as though it had been but recently introduced, and yet its first introduction dates as far back as 120 years. In the early period of its naturalization it would appear to have enjoyed a due amount of appreciation, as I find it alluded to in some of our old books as though it were a moderately common plant; during my experience I have only in one instance met with it in any quantity and in a really flourishing condition, and that was at Messrs. Osborn's nursery at Fulham, which furnished the specimens from which the annexed plate was prepared. No one who glances at the representation here given will dispute its claim to general culture on the score of its beauty; its erect, rigid stems rise to a height of from 6 in. to 12 in., sparsely clothed with sessile, lanceolate, triple-nerved leaves, from a somewhat woody crown; the stems are square, slightly winged at the angles, and the leaves are covered with short, rigid, bristly hairs. It blooms in July and August, the flowers being produced in a successional manner. Its native country, as the specific name indicates, is Virginia; not that it is by any means confined to that State, as, in point of fact, it enjoys a tolerably wide distribution throughout the south-eastern States of North America, where it grows in swampy districts, in which the soil is a mixture of sand and peat, accompanied by a fair amount of superficial solidity. Its wiry roots do not appear to be at all adapted to the spongy material that suggests itself to our minds when the name bog or swamp is mentioned. Culturally speaking it is a plant that may be associated with the *Spigelia marilandica*, recently figured in THE GARDEN; where the one will thrive, success with the other may be reckoned as almost certain; in either case a cool subsoil, freely supplied with moisture during summer, is requisite. The only other species in cultivation, *Rhexia mariana*, differs from this chiefly in the leaves being broader, the hairs sparser and softer, and in the flowers having a purplish tinge; it appears, too, to be more restricted in its geographical range, occurring but rarely out of the State from which it takes its name. Like many other North American plants the foliage in the autumn changes to an intense crimson-scarlet, that renders a mass of the plant almost as conspicuous in its autumnal garb as when in full blossom.

The *Rhexias* are plants that are impatient of too much division, and to give them a fair chance good tufts should be obtained from their native localities. Those secured and planted in a sandy peat bed on a cool clay subsoil, the chances of success are almost as certain as, indeed, are the chances to the contrary, where the plants are broken up into infinitesimal fragments.

Botanic Gardens, Hull.

JAS. C. NIVEN.

Bamboo Rice.—There is a species of *Agave* which is said to blossom but once in a century, and the Bamboo that grows among the hills in the south-east of Mysore is scarcely less wonderful. The natives report that it seeds once every sixty years, and the produce thus yielded at this wide interval of time is known in that portion of India as Bamboo Rice. In the husk it resembles paddy that has been cleansed, but it approaches nearer to the appearance of Wheat, though the grains of this seed are somewhat smaller and longer. The villagers of Chamraj Nuggar Taluk, according to the daily papers, recently repaired to the region where this species of Bamboo is to be met with, and collected immense quantities of the seed, which falls in abundance under the clumps of Bamboo. The seed is swept and afterwards winnowed by hand, and when boiled it is sweet and palatable, and much more satisfying than Rice. A level valley about three miles in length, in the same locality, is one mass of Bamboo clumps, which since last October have been shedding their seeds in profusion.

MEADOW BEAUTY. (RHEXIA VIRGINICA.)

EVERGREEN SHELTER.

We have occasionally urged the value of evergreen belts or screens as a protection against the sweeping winds of winter. The shelter of sheds and other outhouses is excellent as far as it goes, but animals do not always get enough range and fresh air when confined to these buildings; they cost more than the planting of a few dozen trees. Cattle yards should always be shielded from wind by evergreen screens. Many years of trial have proved their peculiar value; they need not be planted so closely as a common hedge. Ten trees of Norway Spruce, planted 6 ft. apart, will in ten years give an efficient screen 66 ft. long and 18 ft. or 20 ft. high, if they have been properly cared for and cultivated well for a few of the first years. A

Fig. 1.

screen like this, on the windward side of a sheep yard, trimmed up or pruned on one side high enough for the sheep to pass under the branches freely, may be the means of saving many of their lives, and it certainly will economize a great deal of food. Such a screen, fitted for both sheep and cattle, is shown in fig. 1. Evergreen screens are likewise admirable protectors for dwellings; they add immensely to both beauty and comfort during drifting snow-storms, for which we care little under their green and genial shelter; they may be planted in irregular masses and groups, and with pleasing effect. It is easy to combine ornamental appearance and protection when the prevailing winds are on the sides of the house where there are no pleasant views. Suppose, for example, that the dwelling represented in fig. 2 suffers most from severe winds from the directions shown by the arrows, and that the best views are towards *a* and *b*, there will be no hesitation as to the position of the sheltering trees. Those shown in the woodcut indicate the

Fig. 2.

manner of their distribution. When the best views occur toward points from which the winds blow, a partial screen may be adopted, which will protect the house, and afford vistas through which distant objects may be partly seen. Or, in building, a site should be selected that will admit of proper planting. Or, the arrangement shown in fig. 3 may be adopted, the dwelling (*a*) being placed where the finest view is seen from it to the left. A dense evergreen plantation is made on the left for shelter, affording enough protection to the smaller shrubs and flower-beds shown in the woodcut between this plantation and the dwelling; but, in order to prevent the entire exclusion of the view on the left, walks are so laid out as to reach easily the summer-house (*b*), which is placed in full view of the extensive prospect on that side. An evergreen screen need not be expensive. The greatest cost is the time required for the trees to grow: this is the price which must be paid for all trees. But if those be selected which have natural vigour, and ample roots be secured at the time of their removal, and the ground be kept well cultivated and mellow

for a few of the first years, they will soon attain a large size. Norway Spruce grows fast, and this tree is, on the whole, best for screens. If not over 3 ft. high, careful removal will not check them more than equal to one year's growth, and unless they have been repeatedly transplanted, this size is as large as should be chosen. In some places, evergreen trees, such as *Arbor-vitæ*, White Pine, Spruce, &c., may be found on the margins of woods, and if the soil be of such a character that a large mass of earth may be taken up with the roots, they will do well. Such trees, if only 4 ft. or 5 ft. high, will be sure to live if they have 40 lb. or 50 lb. of earth in a flat, circular form, on the roots after removal. Those which are 7 ft. or 8 ft. high should have circle of earth 3 ft. in diameter, and should weigh 100 lb. or 200 lb. If nearly or entirely denuded of their roots, the probability is that not one in ten will live, and the few that do survive will be so stunted as not to recover their vigour for years. In selecting such trees, it is important to choose those which have been exposed in some degree in open ground, or on the margins of woods, and to place them where they will not be severely swept by winds. If taken out of woods where they have been exposed to neither wind nor snow, they will not be likely to endure the new exposure. On the whole, it will be found most satisfactory to select Evergreens from nursery rows, as these will grow most rapidly, and make a handsomer and more satisfactory screen. We ("American Cultivator") have estimated that in the course of twenty years we have saved over 1000 dollars'

Fig. 3.

worth of firewood and coal, on account of the protection from cold winds which Evergreens have afforded, to say nothing of the personal comfort and enjoyment of their ornamental appearance.

Effect of Climate on Plants.—Observations made during the Arctic Expedition have brought to light one or two curious facts in connection with the powers of growth possessed by different plants under varying conditions of climate. American research has proved that the seeds of certain plants, if gathered in one climate and sown in another, will germinate earlier or later, and with more or less vigour, according as the new climate is warmer or colder than the old. And even a perceptible change of climate is not required to show these results, a difference of a few degrees only in latitude is sufficient to do so. According to the "Country," Capt. Young, of the *Pandora*, has on board his yacht a curiosity in the shape of a Rose tree, grown in England, which has been on board ever since he left England for the Arctic Regions. When in the Polar cold the tree drooped, and to all appearance, died; but as soon as the vessel reached a warmer climate it revived, and is now in a perfectly healthy condition. The functions of life had been suspended while the tree remained in cold latitudes, but they were not destroyed. This fact is curious, as tending to prove that a tree which will stand frost at all will bear almost any amount of cold; and also that, if its natural growth and development be retarded at the proper season, the plant cannot defer the revival of its development till the next normal period, but will continue its development at the first opportunity, which, in this case, after the intense cold of the Arctic Regions, occurred in the more moderate cold—the comparative warmth—of an English November. It will be interesting to see if this plant will bloom naturally at the proper season next year.

Street Trees.—The planting of trees in some of the principal thoroughfares of London has for some time been occupying attention, and the Mary-lbone Vestry has just decided on effecting this improvement in Hamilton and Upper Hamilton Terrace, St. John's Wood, thus converting the road into an avenue, at an estimated cost of £372, half of which amount will be subscribed by the inhabitants.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 278.)

Cherry.

- (1) *Helena*. So we grew together,
Like to a double Cherry seeming parted
But yet a union in partition.
Two lovely berries moulded on one stem.
Midsummer Night's Dream, act iii., sc. 2.
- (2) *Helena*. O, how ripe in show
Thy lips those kissing Cherries, tempting show.
Ibid, act iii., sc. 2.
- (3) *Cousinance*. And its grandam will
Give it a Plum, a Cherry, and a Fig.
King John, act ii., sc. 1.
- (4) *Lady*. 'Tis as like you
As Cherry is to Cherry.
Henry VIII., act v., sc. 1.
- (5) *Gower*. She with her need composes
Nature's own shape of bud, bird, branch, or berry;
That even her art sisters the natural Roses,
Her inkle, silk, twin with the rubied Cherry.
Pericles, act v. (Chorus).
- (6) *Demetrius of Syracuse*.
Some devils ask but the paring of one's nail,
A rush, a hair, a drop of blood, a pin,
A Nut, a Cherry-stone.
Comedy of Errors, act v., sc. 4.
- (7) When he was by, the birds with pleasure look,
That some would sing, some other in their bills
Would bring him Mulberries and ripe Red Cherries,
He fed them with his sight, they him with berries.
Venus and Adonis.

Besides these, there is mention of "cherry-lips" and "cherry-nose," and the game of "cherry-pit." The Cherry (*Prunus cerasus*) is not a true native, for we have the authority of Pliny for stating that it was introduced into Britain by the Romans. But it has now become completely naturalized in our woods and hedgerows, while the cultivated trees are everywhere favourites for the beauty of their flowers, and their rich and handsome fruit. In Shakespeare's time there were almost as many, and probably as good varieties, as there are now.

Chestnuts.

- (1) *Witch*. A sailor's wife had Chestnuts in her lap,
And mounched, and mounched, and mounched.
Macbeth, act i., sc. 3.
- (2) *Petruchio*. And do you tell me of a woman's tongue
That gives not half so great a blow to the ear
As will a Chestnut in a farmer's fire?
Taming of Shrew, act i., sc. 2.
- (3) *Rosalind*. I'faith, his hair is of a good colour.
Celia. An excellent colour, your Chestnut was ever the only colour.
As You Like It, act iii., sc. 1.

This is the Spanish or Sweet Chestnut, a fruit which seems to have been held in high esteem in Shakespeare's time, for Lyte, in 1578, says of it, "Amongst all kindes of wilde fruites the Chestnut is best and meetest for to be eaten." The tree cannot be regarded as a true native, but it has been so long introduced, probably by the Romans, that grand specimens are to be found in all parts of England; the oldest known specimen being one at Tortworth, in Gloucestershire, which was spoken of as an old tree in the time of King John. It is one of our handsomest trees, and very useful for timber, and at one time it was supposed that many of our oldest buildings were roofed with Chestnut. This was the current report of the grand roof at Westminster Hall, but it is now discovered to be of Oak, and it is very doubtful whether the Chestnut timber is as lasting as it has long been supposed.

Clover.

- (1) *Burgandy*. The even mead that erst brought sweetly forth
The freckled Cowslip, Burnet, and green Clover.
Henry V., act v., sc. 2.
- (2) *Tamara*. I will enchant the old Androniciens
With words more sweet and yet more dangerous
Than baits to fish or Honey-stalks to sheep,
When, as the one is wounded with the bait,
The other rotted with delicious feed.
Titus Andronicus, act iv., sc. 1.

"Honey-stalks" are supposed to be the flower of the Clover. This seems very probable, but I believe the name is no longer applied. Of the Clover there are two points of interest that are worth notice. The Clover is one of the plants that claims to be the Shamrock of St. Patrick. This is not a settled point, and at the present day the Woodsorrel is supposed to have the better claim to the honour. But it is certain that the Clover is the "clubs" of the pack of cards. "Clover" is a corruption of "Clava," a club. In England we paint the Clover on our cards and call it "clubs," while in France they have the same figure, but call it "treffe."

Cloves.

- Biron*. A Lemon,
Longaville. Stuck with Cloves.
Love's Labour's Lost, act v., sc. 2.

As a mention of a vegetable product, I could not omit this passage, but the reference is only to the imported spice and not to the tree from which then, as now, the Clove was gathered. The tree is the *Eugenia caryophyllata*, and the Clove of commerce is the unexpanded flower.

Cockle.

- (1) *Biron*. Allons! allons! sowed Cockle reaps no corn.
Love's Labour's Lost, act iv., sc. 3.
- (2) *Coriolanus*. We nourish 'gainst our senate
The Cockle of rebellion.
Coriolanus, act iii., sc. 1.

In Shakespeare's time the word "Cockle" was becoming restricted to the Corn-cockle (*Lycnis Githago*), but both in his time, and certainly in that of the writers before him, it was used generally for any noxious weed that grew in corn-fields, and was usually connected with the Darnel and Tares. So Latimer:—"Oh, that our prelates would bee as diligent to sowe the corne of goode doctrine as Sathan is to sow Cockel and Darnel." "There was never such a preacher in England as he (the devil) is. Who is able to tel his dylgent preaching? which every daye and every houre laboreth to sowe Cockel and Darnel" (Latimer's Fourth Sermon). The Cockle or Campion is said to do mischief among the Wheat, not only, as the Poppy and other weeds, by occupying room meant for the better plant, but because the seed gets mixed with the corn, and then "what hurt it doth among corne, the spoyle unto bread, as well in colour, taste, and unwholesomnes is better known than desired." So says Gerarde, but I do not know how far modern experience confirms him. It is a pity the plant has so bad a character, for it is a very handsome weed, with a fine, blue flower, and the seeds are very curious objects under the microscope, being described as exactly like a hedgehog rolled up.

Coloquintida.

- Iago*. The food that now to him is as luscious as Locusts, shall be to him shortly as bitter as Coloquintida.
Othello, act i., sc. 3.

The Coloquintida, or Colocynth, is the dried fleshy part of the fruit of the Cucumis or *Citrullus Colocynthis*. As a drug it was imported in Shakespeare's time and long before, but he may also have known the plant. Gerarde seems to have grown it, though from his describing it as a native of the sandy shores of the Mediterranean, he perhaps confused it with the Squirting Cucumber (*Momordica Elaterium*). It is a native of Turkey, but has been found also in Japan. All the tribe are handsome-foliaged plants, but they require room. On the Continent they are much more frequently grown in gardens than in England, but the hardy perennial Cucumber (*Cucumis perennis*) makes a very handsome carpet where the space can be spared, and the Squirting Cucumber (also hardy and perennial) is worth growing for its curious fruit.

Columbine.

- (1) *Arnoldo*. I am that flower,—
Dumain. That Mint.
Longaville. That Columbine.
Love's Labour's Lost, act v., sc. 2.
- (2) *Ophelia*. There's Fennel for you and Columbines.
Hamlet, act iv., sc. 5.

This brings us to one of the most favourite of our old-fashioned English flowers. It is very doubtful whether it is

a true native, but from early times it has been "carefully nursed up in our gardens for the delight both of its forme and colours (Parkinson);" yet it had a bad character, as we see from two passages quoted by Steevens—

What's that—a Columbine?

No! that thankless flower grows not in my garden."

All Fools, by Chapman, 1605.

and again in the 15th Song of Drayton's *Polyolbion*.—

"The Columbine amongst they sparingly do set."

Both the English and the Latin names are descriptive of the plant. Columbine, or the Dove-plant, calls our attention to the "resemblance of its nectaries to the beads of pigeons in a ring round a dish, a favourite device of ancient artists (Dr. Prior);" or to "the figure of a hovering dove with expanded wings, which we obtain by pulling off a single petal with its attached sepals (Lady Wilkinson);" while the Latin name, *Aquilegia*, is generally supposed to come from *aquilegus*, a water-carrier, alluding to the water-holding powers of the flower; it may, however, be derived from *aquila*, an eagle, but this seems more doubtful.

As a garden plant the Columbine still holds a favourite place. Hardy, handsome, and easy of cultivation, it commends itself to the most ornamental garden and to the cottage garden, and there are so many different sorts (both species and varieties) that all tastes may be suited. Of the common species (*A. vulgaris*) there are double and single, blue, white, and red; there is the beautiful dwarf *A. pyrenaica*, never exceeding 6 in. in height, but of a very rich deep blue; there are the red and yellow ones (*A. Skinneri* and *A. formosa*) from North America; and, to mention no more, there are the lovely *A. cœrulea* and the grand *A. chrysantha* from the Rocky Mountains, certainly two of the most desirable acquisitions to our hardy flowers that we have had in late years.

Cork.

(1) *Rosalind*. I prythee take the Cork out of thy mouth, that I may hear thy tidings.—*As You Like It*, act iii., sc. 2.

(2) *Clown*. As good thrust a Cork into hog'shead.
Winter's Tale, act iii., sc. 3.

(3) *Cornelia*. Bind fast his Corky arms.—*King Lear*, act iii., sc. 7.

It is most probable that Shakespeare had no further acquaintance with the Cork tree than his use of Corks. The living tree was not introduced into England till the latter part of the seventeenth century, yet it is very fairly described both by Gerarde and Parkinson. The Cork, however, was largely imported, and was especially used for shoes. Not only did "shoemakers put it in shoes and pantofles for warmness sake," but for its lightness it was used for the high-heeled shoes of the fashionable ladies. I suppose from the following lines that these shoes were a distinguishing part of a bride's trousseau:—

Strip off my bride's array,
My Cork-shoes from my feet,
And, gentle mother, be not coy,
To bring my winding sheet.

The Bride's Burial—"Roxburghe Ballads."

The Cork tree is a necessary element in all botanic gardens, but as an ornamental tree it is not sufficiently distinct from the *Ilex*. Though a native of the south of Europe it is hardy in England.

Corn.

(1) *Gonzalo*. No use of metal, Corn, or wine, or oil.
Tempest, act ii., sc. 1.

(2) *Duke*. Our Corn's to reap, for yet our tithes to sow.
Measure for Measure, act iv., sc. 1.

(3) *Titanus*. Playing on pipes of Corn.
The green Corn
Hath rotted ere his youth attained a beard.
Midsommer Night's Dream, act ii., sc. 1.

(4) *K. Edward*. What valiant foemen, like to autumn's Corn,
Have we mowed down in tops of all their pride.
3rd Henry VI., act v., sc. 7.

(5) *Pucelet*. Talk like the vulgar sort of market men
That come to gather money for their Corn.
1st Henry VI., act iii., sc. 2.

Poor market folks that come to sell their Corn.—*Ibid.*

Good morrow, gallants! want ye Corn for bread!—*Ibid.*

Burgundy. I trust, ere long, to choke thee with thine own,
And make thee curse the harvest of that Corn.—*Ibid.*

(6) *Duchess*. Why droops my lord like over-ripened Corn
Hanging the head at Ceres' piteous load?
2nd Henry VI., act i., sc. 2.

(7) *Warwick*. His well-proportioned beard make rough and ragged
Like to the summer's Corn by tempest lodged.
Ibid., act iii., sc. 2.

(8) *Mowbray*. We shall be winnowed with so rough a wind
That even our Corn shall seem as light as chaff.
2nd Henry VI., act iv., sc. 1.

(9) *Macbeth*. Though bladed Corn be lodged and trees blown down.
Macbeth, act iv., sc. 1.

(10) *Longaville*. He weeds the Corn, and still lets grow the weeding.
Love's Labour Lost, act i., sc. 1.

(11) *Biron*. Allons! allons! sowed Cockle reaped no Corn.
Ibid., act iv., sc. 3.

(12) *Edgar*. Sleepest or wakest thou, jolly shepherd?
Thy sheep be in the Corn.
King Lear, act iii., sc. 1.

(13) *Demetrius*. First thrash the Corn, then after burn the straw.
Titus Andronicus, act ii., sc. 3.

(14) *Marcus*. First let me teach you how to knit again
This scattered Corn into one mutual sheaf.
Ibid., act v., sc. 3.

(15) *Pericles*. Our ships are stored with Corn to make your needy bread.
Pericles, act i., sc. 1.

(16) *Cleon*. Your grace that fed my country with your Corn.
Ibid., act iii., sc. 3.

(17) *Menenius*. For Corn at their own rates.—*Coriolanus*, act i., sc. 1.

Marcus. The gods sent not Corn for the rich men only.—*Ibid.*

Marcus. The Volsci have much Corn.—*Ibid.*

Citizen. We stood up about the Corn.—*Ibid.*, act ii., sc. 3.

Brutus. Corn was given them gratis.—*Ibid.*, act iii., sc. 1.

Coriolanus. Tell me of Corn!—*Ibid.*

The Corn of the storehouse gratis.—*Ibid.*

The Corn was not our recompense.—*Ibid.*

This kind of service
Did not deserve Corn gratis.—*Ibid.*

(18) *Cornwall*. I am right glad to catch this good occasion
Most thoroughly to be winnowed, where my chaff
And Corn shall fly asunder.
Henry VIII., act v., sc. 1.

(19) *Cornwall*. Her foes shake like a field of beaten Corn
And hang their heads with sorrow.—*Ibid.*, act v., sc. 1.

(20) *K. Richard*. We'll make foul weather with despised tears;
Our sighs and they shall lodge the summer Corn.
Richard II., act iii., sc. 3.

(21) As Corn o'ergrown by weeds, so heedful fear
Is almost choked by unresisted lust.—*Rape of Lucrece*.

I have made these quotations as short as possible. They could not be omitted, but they require no comment.

Cowslip.

(1) *Burgundy*. The freckled Cowslip, Burnet, and sweet Clover.
Henry V., act v., sc. 2 (see Burnet).

(2) *Queen*. The Violets, Cowslips, and the Primroses
Bear to my closet.—*Cymbeline*, act i., sc. 6.

(3) *Iachimo*. On her left breast
A mole, cinque-spotted, like the crimson drops
P' the bottom of a Cowslip.—*Ibid.*, act ii., sc. 2.

(4) *Ariad*. Where the bee sucks there lurk I,
In a Cowslip's bell I lie.—*Tempest*, act v., sc. 1.

(5) *Thibet*. Those yellow Cowslip cheeks.
Midsommer Night's Dream, act v., sc. 1.

(6) *Fairy*. The Cowslips tall her pensioners be:
In their gold coats spots you see;
Those be rubies, fairy favours,
In those freckles live their savours:
I must go seek some dewdrops here
And hang a pearl in every Cowslip's ear.—*Ibid.*, act ii., sc. 1.

"Cowslips! how the children love them, and go out into the fields on the sunny April mornings to collect them in their little baskets, and then come home and pick the pips to make sweet, unintoxicating wine, preserving at the same time untouched a bunch of the goodliest flowers as a harvest-sheaf

of beauty! and then the white soft husks are gathered into balls and tossed from hand to hand till they drop to pieces, to be trodden upon and forgotten. And so at last, when each sense has had its fill of the flower, and they are thoroughly tired of their play, the children rest from their celebration of the Cowslip. Blessed are such flowers that appeal to every sense." So wrote Dr. Forbes Watson in his very pretty and Ruskinian little work, "Flowers and Gardens," and the passage well expresses one of the chief charms of the Cowslip. It is the most favourite wild flower with children. It must have been also a favourite with Shakespeare, for his descriptions show that he had studied it with affection. Milton, too, sings in its praise:—

Now the bright morning star, day's harbinger,
Comes dancing from the East, and leads with her
The flowering May, who from her green lap throws
The yellow Cowslip and the pale Primrose

Song on May Morning.

Whilst from off the waters fleet,
Then I set my printless feet
O'er the Cowslip's velvet head
That bends not as I tread.

Sabrina's Song in "Comus."

But in Lycidas he associates it with more melancholy ideas:—

With Cowslips wan that hang the pensive head,
And every flower that sad embroidery wears.

This association of sadness with the Cowslip is copied by Mrs. Hemans, who speaks of "Pale Cowslips, meet for maiden's early bier;" but these are exceptions. All the other poets who have written of the Cowslip (and they are very numerous) tell of its joyousness, and brightness, and tender beauty, and its "bland, yet luscious, meadow-breathing scent." The names of the plant are a puzzle; botanically it is a Primrose, but it is never so called. It has many names, but its most common are Paigle and Cowslip. Paigle has never been satisfactorily explained, nor has Cowslip. Our great etymologists, Cockayne, and Dr. Prior, and Wedgwood, are all at variance on the name, and Dr. Prior assures us that it has nothing to do with either "cows" or "lips." But we all believe it has, and without inquiring too closely into the etymology, we connect the flower with the rich pastures and meadows of which it forms so pretty a spring ornament, while its fine scent recalls the sweet breath of the cow, "just such a sweet, healthy odour is what we find in cows; an odour which breathes around them as they sit at rest on the pasture, and is believed by many, perhaps with truth, to be actually curative of disease" (Forbes Watson).

Botanically, the Cowslip is a very interesting plant. In all essential points the Primrose, Cowslip, and Oxlip are identical, the Primrose, however, choosing woods and copses and the shelter of the hedgerows, the Cowslip choosing the open meadows, while the Oxlip is found in either. The garden "Polyanthus of unnumbered dyes" is only another form produced by cultivation, and is one of the most favourite plants in cottage gardens. It may, however, well be grown in gardens of more pretension; it is neat in growth, handsome in flower, of endless variety, and easy cultivation. There are also many varieties of the Cowslip, of different colours, double and single, which are very useful in the spring garden.

Crabs (see Apple).

Crocus (see Saffron).

Crow-flowers.

Queen. Therewith fantastic garlands did she make
Of Crow-flowers, Daisies, Nettles, and Long Purples.

Hamlet, act iv., sc. 7.

The Crow-flower is now the Buttercup, but in Shakespeare's time it was applied to the Ragged Robin (*Lychnis Flos-cuculi*), and I should think that this was the flower that poor Ophelia wove into her garland. Gerarde says, "They are not used either in medicine or in nourishment; but they serve for garlands and crowns, and to decke up gardens." We do not now use the Ragged Robin for the decking of our gardens, not that we despise it, for it is a flower that all admire in the hedgerows, but because we have other members of the same family as easy to grow and more handsome, such as the double variety

of the wild plant, *L. chalconica*, *L. Lagascae*, *L. fulgens*, *L. Haageana*, &c.

Crown Imperial.

Perdita. Bold Oxlips and
The Crown Imperial.

Wander's Tale, act iv., sc. 4.

The Crown Imperial is a Fritillary (*F. imperialis*). It is a native of Persia, Afghanistan, and Cashmere, but it was very early introduced into England from Constantinople, and at once became a favourite. Chapman, in 1595, spoke of it as—

"Fair Crown Imperial, Emperor of flowers."

Gerarde had it plentifully in his garden, and Parkinson gave it the foremost place in his "Paradisus Terrestrius." "The Crown Imperial," he says, "for its stately beautifullnesse deserveth the first place in this our garden of delight, to be here entreated of before all other Lillies." And if not in Shakespeare's time, yet certainly very soon after there were as many varieties as there are now. The plant, as a florist's flower, has stood still in a very remarkable way. Though it is apparently a plant that invites the attention of the hybridizing gardener, yet we still have but the two colours, the red and the yellow (a pure white would be a great acquisition), with double flowers, flowers in tiers, and with variegated leaves. And all these varieties have existed for 200 years.

As a stately garden plant it should be in every garden. It flowers early, and then dies down. But it should be planted rather in the background, as the whole plant has an evil smell, especially in sunshine. Yet it should have a close attention, if only to study and admire the beautiful interior of the flower. I know of no other flower that is similarly formed, and it cannot be better described than in Gerarde's words:—"In the bottome of each of the bells there is placed six drops of most cleere shining sweet water, in taste like sugar, resembling in shew faire Orient pearles, the which drops, if you take away, there do immediately appeare the like; notwithstanding, if they may be suffered to stand still in the floure according to his owne nature, they wil never fall away, no, not if you strike the plant untill it be broken." How these drops are formed, and what service they perform in the economy of the flower has not been explained, as far as I am aware; but there is a pretty German legend which tells how the flower was originally white and erect, and grew in its full beauty in the garden of Gethsemane, where it was often noticed and admired by our Lord; but in the night of the agony, as our Lord passed through the garden, all the other flowers bowed their heads in sorrowful adoration, the Crown Imperial alone remaining with its head unbowed, but not for long—sorrow and shame took the place of pride, she bent her proud head, and blushes of shame, and tears of sorrow soon followed, and so she has ever continued, with bent head, blushing colour, and ever-flowing tears. It is a pretty legend, and may be found at full length in "Good Words for the Young," August, 1870.

H. N. ELLACOMBE.

(To be continued.)

WATER IN SMALL GARDENS.

THERE are few greater mistakes made in gardens than placing artificial water in small ones. This fault is more frequent on the Continent than with us. There is, however, one virtue in artificial waters seen abroad—they are rarely deep or large enough to drown the children, though ugly enough to irritate sensitive adults. With us the artificial water generally assumes the form of a duck-pond; in France it is much nearer to a hand-basin. There if the "lawn" be only as large as a tablecloth, a tub in cement is sure to find a place on it. Happily in our small gardens water is much seldomer seen. There are good reasons why artificial water should never be seen in a small garden: the effect of still water is only pleasant where it sparkles in the sun in broad masses. Nothing can be much more offensive than small pools of unclean water. Near a dwelling-house they are objectionable for other reasons, besides, the space they occupy is precious for better aims. Good design will not in these cases do much for us or compensate for the error of forming artificial water where there is not abundant room for it without curtailing the space needed for more important objects.

TREES AND SHRUBS.

OPEN SITUATIONS BEST FOR CONIFERS.

SOME observations made from time to time regarding the effects of shade, shelter, light, air, &c., upon the growth of Conifers, and their bearing upon the planting, thinning, and work attending plantations generally, may perhaps interest some of your readers. My notes have been taken with a view to ascertain how far thick planting, with the object of shelter, was advantageous in young plantations. My first notes refer to the Wellingtonia and its rate of growth under different circumstances as regards light and shelter. Eight or nine years ago, among a number of young trees of the same age which were moved, two, as nearly as possible of the same size and girth, were selected. No. 1 was planted in an open but sheltered situation, no trees or buildings being near it; and the other, No. 2, was planted in an open space also, but was shaded by tall trees growing not more than 30 ft. or 40 ft. away from it, otherwise it was much better sheltered from the winds than No. 1; and both were treated alike as regards soil. They were each about a yard high when moved, and fairly furnished with branches, but at the end of the second year after planting No. 1 was by far the bushiest tree, though No. 2 was the tallest; and since that time the disparity between them has increased every year, particularly as regards the thickening of the trunk and branch growth, No. 1 being a fine, densely-furnished tree, with a thick bole, and No. 2 tall and attenuated, both in the stem and branches. When last measured, not a month ago, No. 1 was 12 ft. high, with a bole 9 in. in diameter 1 ft. from the ground, and No. 2 was fully 13 ft. high, and only 4½ in. in diameter in the bole at the same distance from the ground, or just half the diameter of the other. The next instance relates to the Deodar. Of a number of old trees, all of the same age, and about the same height (30 ft. or more), the finest tree, which grows in an open and rather exposed situation, has a trunk 15 in. in diameter; and its near neighbour, only partially shaded, and much better sheltered, measures only 10 in. at the same distance from the ground. Others range between these figures according as their position is a shaded one or otherwise. One of the largest—as to girth—is growing in an exposed situation. Other trees of the same kind, but younger, exhibit still greater contrasts in growth, and their girth appears in every case to be just in proportion to the amount of light and air which they receive. They were all planted about sixteen years ago, and all, except two or three of the number, have been once moved since. Those which were not moved are now 19 ft. high or thereabouts, and measure 8 in. in diameter 1 ft. from the ground; they are growing in an open situation. The others are planted on each side of a glade, and are more or less shaded by tall trees behind, some being more unfavourably situated in that respect than the others. They range from 14 ft. to 17 ft. in height, and the most shaded tree of the number has a stem only 3 in. in diameter, while the thickest measures a little over 5 in., all being measured 1 ft. from the ground. It is needless to state, perhaps, that the trees with the thickest trunks are in every case the best furnished with branches. If we turn to older trees, the same facts are observable. There are some fine Larch trees scattered about the woods here; and, though they are all of the same age, no one would suppose them to be so, judging merely by their dimensions. In their case it is easy to see how much the thickening of the trunk is influenced by the area of branch growth. One

group of trees growing in the bottom of a deep ravine, where they are disadvantageously placed as regards light and air—not to mention the fact of their having been so crowded all their lives as never to have carried more than just a few branches at their tops—are between 70 ft. and 80 ft. high, and not more than 1 ft. in diameter at their base; but this thickness or a trifle less, they carry with them nearly up to where the branches begin, from which point they taper off rapidly. Standing upon one side of the ravine, nearly opposite their middle, one is able to get a fair idea of their girth, and it is noticeable that the thickening process terminates almost abruptly where the branches begin to decay and fall off. Ten feet of green top is about the most which any of the group possesses, and I dare say they carry as many branches now as they ever have done at any former period.

J. S.

BEST METHOD OF SEASONING TIMBER.

THE best method of seasoning timber at present in use is to fell the trees between the end of September and beginning of April, to have Pine logs raised 1 ft. above the ground, and exposed to light and air without shade. Having lain thus for two years, they may be sawn into boards or planks, and stored in a dry but airy shed for another year, before being worked up by the carpenter. Hardwoods ought to be stored in like manner till the bark falls off, when they should be sawn into planking for use. The Sycamore, Maple, and Birch, however, soon become discoloured; the best method is to chip and saw them immediately after the sap is out of them, then store them in a dry shed as above. This process, however, costs much labour and expense. To avoid these, I recommend the adoption of the following method:—Mark all trees which will be useful or saleable during the summer, as sickly plants are then more easily observed. During September ring or girdle all trees marked 1½ in. round the bole where they are to be cut; then allow twelve months to elapse before felling, during which time they will have died, and I believe will have lost nearly two-fifths of their weight, and be fit for sawing up at once. The result would be the en-

Small Lawn with Artificial Water (see p. 298).

hanced value of the timber, which on a largely-wooded property would be considerable. For example, 150 acres of ground are to be cleared, upon which are growing 60 tons of wood per acre, making 9000 tons in all, at a distance of 110 miles from Glasgow per railway, and 6 miles from the nearest station; reckoning the cost of dragging and carting per ton at 7s. 6d., and railway carriage 12s. 6d., total 20s. per ton, the gross expense of transit would be £9000; calculating that nearly two-fifths can be saved by ringing the trees as above described, the cost will be reduced by about 6s. 6d. per ton, equal to £2925, and the gross expense to £9075. Thereby the seller would receive £2925 more for his wood, and, allowing £100 for the expense of ringing the trees, would save £2825. I recommend the above system to all interested in the sale or manufacture of timber, as the best means to get timber economically seasoned and ready for immediate use. Where Birch wood is being used for bobbins, this process of ringing would obviate the need of chipping, and by allowing the trees to stand nine months, they would be ready for immediate use. If the wood be wanted for fence stobs, ringing would render them serviceable the next season, when they might be conveniently charred by their own tops or branches, which would cause them to last double the time in the ground. The process of ringing, then, has two advantages—increasing the value of timber, and seasoning it in the most economical way.—T. WILKIE, in ‘Arboreal-cultural Society’s Proceedings.’

A Useful Wall Plant.—The most attractive plant now to be found on the walls at Kew is probably *Prunus triloba*. It is literally covered from top to bottom with pale pink and rosy blossoms, the beauty of which is greatly enhanced by their being associated with Ivy and other Evergreens.—S. C.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Fuchsias, that flowered last summer and were cut back during the winter, started, and re-potted some time ago, will come into bloom early; to further advance them in this respect the young shoots should not be stopped more than once. Cuttings struck at the end of last summer, and kept going in a little warmth through the winter, make much the handsomest specimens for flowering in either a small or large state; if wanted to bloom as early as they can be had, the roots must not have too much room—6-in. or 8-in. pots will be sufficiently large; it will be well to move a few into 12-in. or 13-in. pots—these will make fine plants, and will succeed those that bloom earlier. To induce a disposition to flower late in the season, the points of the shoots will require stopping twice or thrice after the present time. The front of a Vinery at work will suit them admirably, as they will be somewhat shaded, which condition favours growth more than the production of flowers; and if exposed to the full light after this time they will have a greater disposition to bloom than to make growth. Syringe them well overhead every day to keep down red spider; if this insect obtain a footing upon them at the present time, it quickly disfigures all the foliage, and makes the plants unsightly.

Pelargoniums.—Large-flowered and Fancy Pelargoniums should now be kept at a temperature of 45° in the night, syringing them slightly overhead in the afternoons at the time the house is closed; the pots ought to be elevated so that the heads of the plants are as near the glass as possible; by this means both foliage and flowers will be much stouter, the plants requiring much less artificial support by sticks and ties.

Amaryllis and Vallota purpurea.—Plants of Amaryllis that are now pushing up their flowers must be well supplied with water; weak liquid manure will be of great assistance to them, especially the deciduous kinds, that make the greater portion of their leaves for the season simultaneously with the growth of the flower-stem; they should have plenty of light, otherwise the leaves will be drawn up, a defect which no subsequent treatment through the season can remedy, and it is upon the production of the greatest quantity of healthy foliage that next year's flowering is in a great measure dependent. The nearly-allied Vallota purpurea will now be making its growth; the soil must not be allowed to become dry, or the plants will be much injured. This is one of the most useful late summer and autumn-flowering plants we possess; it is also one of the best window plants that can be grown, requiring little space and thriving well in an ordinary sitting-room. If a few plants could be placed in a Vinery at work, or in any position where they will receive a somewhat greater heat than they would in an ordinary greenhouse, they will flower earlier, and by subjecting another portion of the stock to cooler treatment they will afford a succession of bloom. Vallotas may be increased very fast from the numerous offsets they produce, which are readily separated from the larger bulbs without disturbing them; if these offsets be now taken off and inserted (six or eight together) half their depth in 4-in. pots filled with sandy soil and subjected to ordinary greenhouse treatment, they will grow on and make fine, healthy, blooming plants in the course of two or three years.

Vines started some time ago will now be coming into bloom; there is little difficulty in inducing such kinds as Black Hamburgh and White Frontignan to set, but where Muscats are grown, especially when mixed with Hamburghs, they are not so easily managed, as they require more warmth, yet the high night temperature frequently recommended for Muscats need not be kept up, as they may be induced to set freely without. The point to be observed is that, during the time of blooming, the daily temperature is raised sufficiently by combined sun and fire-heat, and in sunless weather by fire alone, accompanied with a sufficient amount of air to dry the atmosphere of the house, and thus cause the more easy dispersion of the pollen; and whilst the atmosphere is dry, the canes or wires to which the shoots are tied should be struck freely with the hand from bottom to top; the vibration thus produced will greatly assist the fertilization: it will be well to repeat this shaking process twice or so during the middle of the day. Cease syringing from the time the first flowers expand, but do not keep the atmosphere too dry morning and evening. Where there are Vines that it is desirable to retard as late as possible, it will be well to keep them tied across the front of the house as low down as convenient, admitting air at the front lights, as in this position they will not be much under the influence of the sun, and consequently cooler than if tied to the wires near the glass. As to the temperature kept up in a house where such late Vines are grown it will, of course, depend upon what pot plants are required to be grown in the house. Amateurs

generally want to accommodate many subjects besides the Vines; therefore it will be necessary to give some consideration to the requirements of the pot plants, which would not well bear the admission of such a volume of cold air as the Vines would stand, and which would be an assistance in further retarding them; but a good deal may be effected by admitting it at the opposite point from where the wind blows: for instance, if coming full upon the front lights, open the roof ventilators or shutters in the back-wall freely, leaving some on at night, being careful that the inside temperature does not fall below the freezing point, as nearly all greenhouse plants will suffer more from too low a temperature when growth has commenced than when dormant, and when less water was needed at the roots.

Annals.—The almost unprecedentedly wet condition of the soil resulting from the continued autumn and winter rains has hitherto rendered it necessary to postpone beyond the usual time the sowing of nearly all kinds of seeds: hardy annuals will be no exception. In such a season as the present the difference in the condition of light, sandy soils from those of a heavier, adhesive character will necessitate considerable variation in the time of sowing seeds of many kinds of plants, especially those of a small size, for although it is always advisable to put in seeds of annuals sufficiently early, that the plants may attain good hold of the ground before dry weather sets in, yet from the cold, wet condition of the soil in many localities this spring, if sown too early they will rot. It is much better to wait a little than to run any risks in this matter, for even should the seeds germinate, until there is sufficient warmth in the soil, the plants make such slow progress as to become a prey to slugs, which are always unusually numerous during a cold, wet spring. I should recommend the sowings of the seeds of annuals to be made completely on the surface, choosing a dry day, smoothing the soil with the rake where the patches or rows are to be, on which scatter the seeds, covering with some dry loose material, than which nothing is better than old potting soil, in which such things as Fuchsias, Pelargoniums, Calceolarias, Cinerarias, or any plants that are annually shaken out have been grown. If this soil have been kept in a shed under cover, and be mixed with a little burnt or charred refuse, wood ashes, or fine-sifted coal ashes, the mixture will not only assist the seeds to vegetate, but will to some extent prevent the slugs from attacking the plants. Since ordinary bedding plants came so much into fashion, hardy annuals in many cases have not received the attention which they deserve, and yet amongst them may be enumerated some of the most beautiful flowering subjects we possess. Against their use it is frequently urged that their blooming is of short duration, but in the case of many this is frequently attributable to the indifferent treatment they receive; it is often considered that any situation where nothing else can be got to grow is good enough for them, consequently they are sown partially under the shade of trees that have impoverished the soil to an extent that no plant can exist in it. The nature of an annual is such that its growth must be quick, and it is well known the quicker the natural growth of a plant the more essential is it that it should have abundant food in the shape of thoroughly enriched soil. Where the ground is at all poor, plenty of good manure, and where heavy and retentive, leaf-mould in addition should be pointed in 6 in. or 8 in. deep. Another cause by which annuals have frequently not the most remote chance of exhibiting their true character, or continuing to flower for their allotted time, is that they are sown so thickly, and not thinned afterwards; or, if this latter operation be performed at all, it is not nearly carried out to the requisite extent—the result is, that the plants stand as close as weeds in a foul garden. Even such common subjects as Nemophilas, Mignonette, Malvas, Lupines, Linums, Larkspurs, Gillias, Gaillardias, Esehseholtzias, Erysimums, Dianthus, and others, should always have as much room allotted to each individual plant as will permit of their growing on to their full natural size without encroaching upon each other; by this means they attain a character, and continue flowering for a length of time, which they are otherwise incapable of doing when both roots and tops are overcrowded. Strong-growing, large-spreading varieties of Nasturtiums, climbing Convolvulus, Sweet Peas, and similar plants should have an open situation, and also plenty of room. The Helichrysms, of which there are now so many splendidly-coloured varieties, of dwarf, compact habit, should not be sown before the end of the month in dry, light soil; where the ground is wet they are better sown in boxes or pots, and transplanted. Dried natural flowers can never be so attractive as fresh living ones; yet, if these Everlastings be cut within a day or two of the flowers opening when the colours are at their brightest, and dried quickly by hanging up in a room where a fire is kept, they can be made into most attractive groups with dried Grasses for the embellishment of vases through the winter. If the beautiful tints and varieties of this flower, as it now exists, were better known, they would be much more generally cultivated.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

April 16.—Potting Achimenes; shaking out and repotting Solanums, and placing them in heat. Shifting Balsams into 8-in. pots. Sowing Veitch's Autumn Giant and Walcheren Cauliflowers, Veitch's Protecting, Cooling's Matchless, Snow's Early White, and Dilcock's Bride Broccoli; also Red and White Cabbage. Planting out frame-sown Lettuce and Cauliflower plants. Putting standard *Maréchal Niel* Roses into Peach-house; also 100 pots of Musk. Placing Camellias in heat. Making Melon-pit ready for planting.

April 17.—Potting off tender annuals, Vine eyes, and Fuchsias. Shifting all stove plants that require it into larger pots; also Chrysanthemums without stopping their shoots. Sowing Mignonette on borders; also Cottager's Kale, Cocoa-nut Cabbage, White Cos, Alexandra and Neapolitan Cabbage Lettuces, Cucumbers, and Melons. Planting Globe Artichokes and Lettuces from autumn-sown seed-beds; also planting a border of autumn-sown Cauliflower plants that have previously been pricked out. Pricking out Celery in frames; also Sweet Basil, Marjoram, and Ice plants. Putting Heaths into cold pits. Picking dead flowers off Indian Azaleas and placing the plants in a warm greenhouse. Getting bulbs that have been forced in pots from under greenhouse stage and placing them under the protection of a wall out-of-doors. Sanding, rolling, and otherwise putting walks in good order. Digging vacant land and hoeing among growing crops.

April 18.—Putting Caladiums into 10-in. pots. Shifting Tree Mignonette and young Vines, and potting Perillas and Centaureas in 4-in. pots. Sowing Fulmer's French Beans, Salsafy, Scorzonera, Ivory's Pink Nonosuch Celery, and Radishes of different kinds. Planting out *Cerastium tomentosum* and Strawberries. Spawning Mushroom-bed and afterwards firmly heating it down. Pricking out first batch of Cinerarias, Primulas, and Herbaceous Calceolarias. Putting in cuttings of *Begonia parviflora* and Chrysanthemums. Thinning autumn-sown Onions. Sticking Peas and putting Narcissi in pots just coming into flower under wall out-of-doors, in order to prolong their blooming.

April 19.—Potting Cockscombs, Tuberoses, and Victoria Ten-week Stocks. Sowing Scarlet Runners in rows 5 ft. apart, and more Mignonette out-of-doors; also Blue-branching Larkspurs, Celery out-of-doors, and some in a box placed in heat. Planting Dwarf Curled Borecole for seed, Carnations, Borage, and more Cauliflowers. Transplanting spring-sown Onions, to fill up gaps in main bed where plants have failed to come up. Pricking out seedling and double red Daisies. Putting in cuttings of *Achyranthes Lindenii*. Staking last potted French Beans. Earthing up Melons. Hoeing among Raspberry plantations. Stopping late Vines. Emptying and refilling winter Cucumber-pit. Putting Centaureas in cold frames, and Tuberoses in lean-to pit, and putting cases over two or three rows of Black Prince Strawberries that are coming into flower. Stopping shoots of bedding Calceolarias, and tying up more Lettuces.

April 20.—Potting *Lobelia Paxtoni*, *Nepetas*, and *Chamaepeuce diacantha*, shifting a few Palms into larger pots, and potting off *Celosias* and *Prince's Feather*. Re-blocking *Dendrobium Falconeri*, and basketing *Dendrobium Wardianum*. Sowing Sweet Peas in pots; also Mignonette, Vegetable Marrows, Malope, another frame of Early Horn Carrots, and a border of Paxton French Beans. Planting out forced Tulips and Lily of the Valley, second-sown Melons, and spring-sown Lettuces. Putting in cuttings of *Coleus*, *Ageratums*, *Salvias*, and *Gladiolus* into cold frames. Hoeing among spring-sown Onions. Pulling up and wheeling away Brussels Sprout stumps. Placing forced Roses under back wall, where they can be readily protected with mats in case of cold weather. Putting a little soil on Asparagus beds, and taking all French Beans from shelves in houses in case they should harbour red spider.

April 21.—Potting *Celosia pyramidalis*, *coccinea*, and *aurea*. Shaking out and re-potting large standard *Heliotropes*. Blocking *Dendrobium pulchellum* and *Oncidium bifolium*. Sowing Nonpareil and Champion of England Peas, Broad Beans, Spinach, and Walcheren Cauliflower. Planting Black Prince Strawberries, *Gladiolus*, *Dielytra*, and Sweet Briers. Pricking off Celery under glass protectors. Putting in Pink cuttings on hotbed. Thinning Carrots in frame; also early-sown Turnips. Raising Cauliflower protectors on bricks, staking Sweet Peas, and watering Cauliflowers under hand-glasses with manure water. Top-dressing Peach trees.

PEAS AND THEIR CULTURE.

The garden Pea and the field Pea are by some thought to be only varieties of the same species, the garden Pea being supposed to have, through long cultivation, departed farthest from the original type; but most people are of opinion that they are distinct. The field Pea has red flowers, and only one bloom on each flower-stalk; while the garden Pea has mostly white flowers, and produces two or three on each stalk; and these are the chief points of difference between them. Both are natives of the south of Europe, and have been cultivated there and in the East from very ancient times. The Pea is believed to have been introduced into this country about the Middle Ages; but Peas were not common as late as the time of Queen Elizabeth, for it is recorded that they were then imported from Holland, and were considered a scarce and expensive dainty. Since then the culture of the Pea has extended to every country where it can be grown successfully as a green vegetable, and there are possibly few of our common esculents that have such a wide geographical distribution, its culture extending from India even to the Arctic circle, or further. In no country has the culture and improvement of the garden Pea received more attention than in England, and we now possess many excellent varieties, though by far the greater number enumerated in catalogues are either comparatively worthless or are simply old sorts with new names. In Loudon's "Cyclopædia of Gardening," dated exactly fifty years back, we find the varieties then described as "numerous," and a list of two dozen of the best is given. Since then, perhaps, scores of varieties have come and gone, and at the present time some seedsmen's catalogues mention no fewer than 100 sorts. To say that twenty-five only of that number are really distinct or well worth growing is probably speaking well within the truth. Take an example:—One of our most trustworthy seed catalogues, speaking of the late trials of Peas, states that "nine-tenths of the new Peas, excepting of course Mr. Laxton's hybrids, are either the old British Queen or *Ne Plus Ultra*"—two of our best and oldest marrows, and which we have always grown for our main crop, and recommended often during the last dozen years or more. The above statement refers, however, only to late varieties; but the same might possibly be said of others. Comment is therefore needless on the subject of "new Peas," which the public buy at extravagant prices.

Culture, Soil, and Manure.

The Pea will succeed wherever ordinary vegetables thrive, but a calcareous soil suits it best; and when the soil is deficient in lime it must be added to it in some form or other, particularly if it contain much vegetable matter or humus, as mostly all old garden soils do. The ground should be deeply trenched and otherwise rendered permeable to the roots, for the Pea is a gross feeder, and the deeper its roots are encouraged to go, the less likely is it to be attacked by mildew, for a deep and open soil affords the most constant supply of moisture to the roots, and dryness is the chief cause of mildew. Of course, deep trenching is not absolutely necessary, though advisable; but the ground should at least be deeply dug, and the Pea in such a case should never follow any other very exhausting crop, if good or even fair returns be expected. Farmyard manure, rotten stable litter, old hotbed material, rotten leaves, decomposed vegetable refuse from the rubbish-heap, and such like, are all excellent manures for the Pea, and perhaps safer and preferable to artificial manures, which are uncertain in their effects. Good crops have been produced by guano in some cases, and in others the results have not been so satisfactory, the tendency of such stimulants being to produce rank growth and little crop. Any of the above manures may be applied in a rank state, provided they are dug deeply into the ground some months previously to sowing the seed; and I should always recommend manure to be dug in with the single spit in preference to trenching it and burying it out of reach for the time being; but very rotten manure may be dug in along with the crop.

Early Crops.

These are usually sown from November till March, and for the very earliest crop the seed is sown in small pots under glass, but not in strong heat, hardened off, and planted out

about the middle of March. Very little, if anything, is gained by sowing in November, but the first outdoor sowing should be got in by February at the latest. A warm corner or south border should be chosen for the early crops, and the rows should run north and south as a matter of course. The distance between the rows must be regulated by the height of the Peas. Those which grow 3 ft. or 4 ft. high should be allowed that distance at the least, and Spinach may be sown between them, and between the rows of the taller kinds Cauliflowers may be planted. In this way no space is lost, and the Peas are greatly benefited by the extra room and sunlight thus afforded them. For dwarf kinds I never allow less than 3 ft., and the tallest are allowed 9 ft. The drills may be about 3 in. deep, and if the seed be of fair quality, a pint should sow a row 40 ft. long at the very least, and seeds of rank-growing kinds should go considerably further. Early sowings should consist of first earlies, such as Carter's First Crop or Dillestone's Early; seconds, such as Daniel O'Rourke or Sangster's No. 1, which come in about ten days later, and are better bearers; and thirds, such as Laxton's Supreme, Auvergne, or Essex Rival. The last is a very prolific Pea, and otherwise good. It is not advisable to sow a greater variety than these, but rather a good breadth of each, in order to have something like good gatherings while each sort lasts.

Second Early Crops.

To succeed the above a sowing should be made at the same time in the open quarter, and the earliest rows of this batch should consist of third earlies, such as Laxton's Supreme and Essex Rival, for the very early kinds are worthless after these come in, and need not therefore be continued. The other rows may consist of Prizetaker, Laxton's Superlative, and Princess Royal, or any of the good second and third early round-seeded kinds. These sowings will carry the supply on till midsummer, and to succeed them another sowing must be made in a month or five weeks after, but not later than the beginning of March, and partly of the same varieties, with a few of the early marrows, such as Alpha and Advancer, and Veitch's Perfection. This brings us fairly into the marrows, and the next sowing should be made about the beginning of April, and should consist principally of good breadths of Veitch's Perfection, Ne Plus Ultra, and British Queen, which succeed each other, with a few of the later round-seeded sorts for common use; but for a supply from July till the end of October I have never had occasion to sow any but the three last named. They will grow and bear as late as any, and are far preferable to early sorts sown late. The last main sowing must be got in early in May, and another between that and the end of the month; this last will not "come in" in cold localities in ordinary seasons, but it should be tried for a chance crop in case a hot autumn should hurry the crops over sooner than usual.

Staking and General Culture.

Peas should always be staked before they produce tendrils; besides, the stakes afford them considerable shelter and

encourage growth. The rows should be slightly earthed up first, and if ordinary Pea-sticks be used, they should be as tall as the Peas are likely to grow. To save expense and trouble in making the stakes, I always use the best of last year's stakes for the early Peas; their bottoms being decayed, they are chopped off, and they are then just tall enough for the earlies and second earlies, which are mostly of a dwarf habit than late Peas. The lengths most needed are 3 ft., 5 ft., and 7 ft. Where sticks cannot be had conveniently, strong sheep nets stretched along each side of the row, and supported here and there by stout stakes, are an excellent substitute. As regards culture, except keeping the ground clean and stirred between the rows, the Pea wants little attention after staking. In dry seasons, a good thick mulching of rotten manure, litter, or short Grass spread along the rows on each side, and about 2 ft. out from the stakes, is highly advantageous, not only improving, as it does, the quality and abundance of the crop, but also prolonging it very considerably. Mulching reduces the necessity of watering very much, but water may be given whenever there is time to apply it; there is no danger of over-watering, for the Pea absorbs an enormous amount of moisture from the ground, which is usually dry in the vicinity of the row. In gathering, the most forward should be diligently sought for, as when the pods are allowed to get old, growth soon ceases and the supplies come to an end.

J. S.

Ice Flowers on Window.

ICE FLOWERS.

Who has not admired the fantastic floral devices that may often be seen on frozen glass through the crystallization of water during hard frost in winter? These are so interesting and beautiful that for some time past endeavours have been made to reproduce them in drawings, but the most exact likeness of them has been obtained by means of photography. This has been done by M. A. Martin-Flammarion, and the accompanying engraving, taken from his stereotype, proves how well he has succeeded. No great stretch of imagination would be required to believe them to represent a bouquet

of delicate flowers and Fern leaves, embroidered on a thin curtain of light and shade. A few years ago M. Haas succeeded in fixing these charming devices on glass in the following manner:—He exposed to the cold a horizontal sheet of glass slightly covered with water, on the top of which was put some enamel powder. The rime formed itself, and when the ice evaporated the floral representations were formed in enamel. Placing the glass thus prepared in an oven, the enamel, in melting, fixed in a durable and permanent manner the crystallizations.

Tree Planting in Algeria.—The railway companies of Algeria had, up to June 1, 1875, planted on the way from Algiers to Oran 14,400 fruit trees, 95,900 forest trees, and 341,000 trees of different species, on the open plains and slopes, making in round numbers 457,000 trees. Since then the number has been sextupled, the company estimating the number actually planted by it on the line as nearly 3,000,000.

VENTILATING FORCING-HOUSES.

THE possession of lax notions about ventilation or air-giving, as it is commonly termed, is often productive of unfortunate results. The presence of red spider, mildew, rust, scalding, &c., is mainly due to imperfect atmospheric conditions, of which defective ventilation is a primary cause. Inexperienced or young men are sometimes apt to think that those who insist upon the necessity of early air-giving and admitting it in very small quantities, gradually increasing it as the sun gains power, are unnecessarily fussy in their method of ventilation. It may seem to some who have not studied the subject practically that in ventilating forcing-houses early in the season, one might as well put on 6 in. as 2 in., and so save trouble. Now I consider that the true principle of ventilation as applied to forcing-houses of ordinary construction, is to admit air—when not absolutely frosty—as soon as the sun shines full upon the roof of the house in the morning by opening the roof ventilators an inch or so; this will prevent the deposition of moisture on the fruit and foliage by the increasing temperature, which, if rapidly evaporated by the admission of large volumes of cool air, tends to chill and check the young growth. This is generally the result when the houses are closed till eight o'clock or later in the morning, when the sun is shining brightly, and the lights are thrown open too widely, for the purpose of keeping down the rapidly rising thermometer. The conditions most favourable for healthy growth are a steady rise of temperature in proportion to the increasing light and warmth of the sun till the maximum is reached, and closing early, and forcing the inmates as much as possible when the air is pure and the light strong. Ventilation, to be perfect, must never be subject to rapid fluctuations. There are good cultivators who insist that air should be left on in forcing-houses all night, not only at the time the fruit is ripening or colouring, but at other times; but there is so much difference in the construction of glass houses, that what may be necessary in one case would lead to a waste of fuel in another. If all forcing-houses were air-tight, then in all cases some means of gradually changing the atmosphere in hothouses without greatly depressing the temperature would be necessary.

The best way of admitting night air early in the season is to pass it between or over the hot-water pipes. It is now nearly thirty years since I saw the first attempt made of changing the vitiated air in forcing-houses during the night, or at any other time when the lights could not be opened; only in those days we had flues instead of pipes. It will thus be seen that this is a very old subject, only its advocacy then was confined to a few. In the case I am referring to the air was admitted by an underground drain, and brought up inside the house near the warm flue, so that the current of air was warmed as it ascended and became mixed with the surrounding atmosphere. As regards the propriety of night ventilation it must not be forgotten that to a certain extent it is continually going on, especially in old-fashioned houses; indeed, in such houses on cold spring nights, an excess of the cold exterior atmosphere frequently gains admission through the open spaces between the squares of glass; therefore in arguing for or against night ventilation, it should be borne in mind that it is more a question of degree than of principle, as it is not likely that glass houses will ever be constructed air-tight. But in building glass-houses at the present period the tendency is to use larger panes of glass, with consequently fewer air spaces; therefore the state of things is somewhat different from what formerly existed. What seems to me to be really required is a fairly equable temperature, corresponding in some degree with, and to bear some proportion to, the fluctuations outside, at the same time to be kept in a constant state of circulation and renewal so far as can be effected without causing cold draughts or currents of air. Of course the heating apparatus will keep up the circulation, but it cannot change or renew the atmosphere. As the season advances and the sun gains power, the occupants of many houses would benefit by having the top ventilators opened an inch or so the last thing at night, as it is generally too much to expect any cultivator but the most enthusiastic to rise with the sun for the purpose of giving air. But every house should be considered separately, due allowance being made for its position, construction, &c.; and small

houses require more care and attention than large ones. This subject (night ventilation) is, I think, deserving of much consideration. I have before remarked it is not new, as I believe it has, to a certain extent, occupied the attention of cultivators since hot-houses for fruit or plant culture were first introduced. If it be right to assume that the leaves of plants are the lungs or organs of respiration, it will at once be seen how important it is that the conditions under which they are produced, should be such as will be suitable for ensuring healthy, substantial foliage; the whole question of fruitfulness must in the main hinge upon this. A damp, close atmosphere, especially when maintained at a very high temperature during night, is conducive to the production of soft, flabby growth and foliage that will always be liable to succumb to sudden gleams of bright sunshine, or to fall a prey to red spider or some other ailment before the season is half over. In conclusion, whatever ideas may be entertained by cultivators about air-giving generally, either during the day or night, there should, I think, be no difference of opinion about the advantages of early closing, and keeping the houses closed till the evening. The afternoon is the best and most natural period of the day for expediting forcing; even in the case of unheated houses—such as orchard-houses—early closing, securing the sun's bright warm rays, and at the same time saturating the atmosphere with moisture, have a most beneficial influence upon the size and quality of the fruit, in the evening admitting air through small openings at convenient intervals to prevent stagnation.

E. HOBDAY.

ACHIMENES GROWN IN BOXES.

HAVING last summer to furnish a number of greenhouse shelves on which pots were unsightly, the thought struck me that Achimenes in small, shallow boxes would answer the purpose—which they did—admirably. I found, too, that boxes had many advantages which pots or pans do not possess. They do not require half the amount of water, a great advantage; for when once Achimenes suffer from want of water, they get crippled for the season. Moreover, tying and staking are almost done away with, as the plants are grown in rows in the boxes, and all that is required is a stake at each end of the row and a piece of wire extending from one stake to the other pressed into a slit on the top of the stake. Each little plant should be tied to the wire when 6 in. high, which is all that will be required. Grown in this way they have been very much admired by all who have seen them—they were so robust, and every leaf and flower so perfect. I have been asked how I managed to support them without stakes, the wire just alluded to being quite hidden from view. Nevertheless, it keeps them in their place, and if too crowded when they grow up, all that is required is to press the stakes a little towards the edges of the box, when the whole row becomes opened up in a most satisfactory manner. This mode of growing Achimenes may not be new to some; but to all who are unacquainted with it I would say give it a trial, and I have no hesitation in asserting that they will ever afterwards give up growing them in pots or pans, except for special purposes. The following are the dimensions of the boxes which I use, and which are elegant, light, and durable. Their length is 16 in.; breadth, 8 in. at the top and 5 in. at the bottom; depth, 5 in. Half-inch white deal is quite strong enough, and when first made they should have two coats of paint and one every year afterwards, which will preserve them for a number of years. They are bottomed lengthwise, using two boards 2½ in. wide, which leaves 1 in. of space all the way along to provide for drainage. Thirty-two tubers are needed to furnish these boxes properly, that is, four lines consisting of eight tubers each. Grown in this way they are easily managed.

THOS. SPELMAN.

Forwardness of the Season.—Much has been written on this subject, but here the season is at least a month behind the usual time. My note book says, February 23, 1875, Cherry and Plum Trees in full bloom—while this season it was March 30th before they blossomed. The mildness of the winter made people believe that the season would be early, but the wet sodden state of the land has kept vegetation backward.—R. GILBERT, *Burghley*.

Gold-laced Polyanthuses.—I am surprised that "D." (see p. 184) finds any difficulty in procuring these. Three years ago I purchased a packet of Polyanthus seed, and amongst the plants raised from it were scores that produced gold-laced flowers of good form and substance—quite equal in these respects, indeed, to many collections which I have seen staged at South Kensington and other exhibitions. I have no doubt that if "D." were to obtain his seed from a respectable firm, as I did, he would meet with the same result.—JOHN G. T. COCKS, *Clapham Park*.

NOTES ON HARDY FLOWERS.

ASPERGERS.—No time should now be lost in getting these sown. So little seed was saved by the foreign raisers in 1876, that that saved in 1875 has to be mainly depended on; the crop will therefore be thin and the growth tardy, and the quicker the seed is sown the stronger will be the plants at planting-out time at the end of May.

ANNUALS.—Now is a good time to sow these. Many annuals are spoilt by being sown thickly on a hard, unbroken surface. If cultivators would only sow a great many of their annuals, at least the hardiest among them, in autumn to stand the winter, they would have them very much finer in spring and early summer than they are when sown in April and May. During the winter they root well into the soil; they make a good growth in spring, and come into bloom gradually, freely, and continuously. In early summer dry warm weather brings the plants into flower before they have made their growth, and they are soon over. Those who sow now should stir deeply, use some fine, rich soil, and press the whole firmly down. All strong-growing annuals, such as Nasturtiums, Sweet Peas, *Convolvulus major*, *Eschscholtzias*, Malope, Lupines, &c., cannot be expected to flourish unless they are growing in a rich holding soil.

ANRICALAS.—These are fast coming into bloom, and will need abundant supplies of water during dry weather. On no account should the plants be sprinkled overhead, or the water will damage the expanding flowers. We are keeping our plants somewhat close, but fully exposed to light, and they are making a fine growth and throwing up bold trusses. As pot plants the Alpine varieties are very beautiful, but in order to have the edging as pure and well defined as possible, they should be grown in poor soil.

PRIMULAS.—These are now very beautiful, especially such kinds as *P. nivea*, *P. ciliata intermedia*, *P. denticulata*, *P. pulcherrima*, *P. purpurea*, *P. amona* and its varieties, *P. marginata*, and others, and being on the whole easily cultivated, they should be grown by every one who is fond of hardy flowers. Those interested in Auriculas and Polyanthus should attend the exhibition of the National Auricula Society, which is to take place at the Crystal Palace, Sydenham, on April 24.

DOUBLE DAISIES.—These are now very attractive, and as there are several varieties in cultivation, an interesting collection may soon be formed. Such varieties as Early Gem, Blood Red, Common Red, Giant White, White Globe, Pink Queen, and Pink Beauty make a charming collection. Then it is a pleasing occupation to raise some from seed provided the latter be good. It should be sown now in a shallow box or bed in a cold frame, pricking out the young seedlings when large enough to handle, and in autumn finally planting them out in beds to bloom in spring.

HYACINTHS.—Those in pots are now going out of bloom, and many are puzzled to know what to do with them. My plan is to plant them out under the protection of a wall in an out-of-the-way place where they can remain for years. A good deep trench is dug, and the plants are turned out of their pots, and planted in it, pressing the soil firmly about them. From bulbs treated in this way, many a posy of fragrant blooms may be cut in early spring.

PANSIES.—Seedlings are now fast opening their flowers, and every day something new will be produced; the best should, therefore, be lifted and re-planted in prepared beds for summer decoration, and the inferior ones may be thrown away. I have planted some of the best-named varieties, both show and fancy kinds, out in beds, and they are growing freely. It is a good plan to peg the shoots firmly to the soil, in order to keep them from wind-waving. If any one wishes to have the rich-belted, white-yellow ground and self-coloured Pansies in full beauty, they should grow the plants in 1½ in. and 6 in. pots, in cold frames, and when coming into bloom, water them with liquid manure. This is how the fine Pansies seen at the exhibitions years ago used to be grown.

PYRETHRUMS AND RANUNCULUSES.—Double varieties of Pyrethrums, planted out to flower in beds or borders, will now need looking after, as slugs are apt to eat their young growths. Ranunculuses must now be encouraged to make all the growth possible, the bulbs having been planted late this spring, owing to the wetness of the season. Many fine Ranunculuses are lost through excessive moisture; therefore, it is well to cover the beds during the heavy rains early in spring, before growth commences.

TULIPS.—Beds of Tulips need all the light and air possible while the weather is mild. Choice Tulips are making generally strong growth—a sure precursor of fine bloom. At this time of year the great danger of Tulips is a sharp frost following a heavy rainfall. On this account growers of choice varieties keep a covering on their beds, which can be lifted so as to fully expose the beds, or dropped to cover them, as may be necessary. D.

Tomatoes in April.—Now that Tomatoes have become popular in our markets, growers have turned their attention to the production of this useful vegetable, not only as a summer outdoor crop, but also as an early spring crop under glass. Mr. Bennett, Rabley, has a large house planted with them, and they are now in full bloom, and if all go well, it is expected that they will be ripe towards the end of next month. The plants are growing in narrow beds on each side of a span-roofed house, and are trained up wooden laths placed 5 ft. or 6 ft. apart. By keeping the shoots tied closely to the laths they obstruct comparatively little light from such subjects as Ferns, Lycopods, &c., which are grown underneath them, and thus all available space in the house is occupied to the best advantage.—S.

Potato Shoots v. Sets.—While residing last year in Switzerland, I made the acquaintance of a horticulturist employed by the government as manager of nurseries, of public institutions, and lecturer in cantonal schools, and with his permission I beg to communicate the result of his last experiment respecting the Potato. Last spring he had arrived at the conclusion that the shoots or germs should be used as seed instead of the tuber. He therefore planted a field with Potato shoots, 2 in. to 7 in. long, leaving about 1 in. above ground, adhering in other respects to the old mode of cultivation. Though the season was very late, the operation taking place at the end of May, he not only had a fine crop, but, by its ripening earlier than if planted by the old method, he was able, I believe in July, to put in the same ground a second crop, which came to maturity and produced very fine tubers, which I saw. The shoots should be taken off at the eye and not broken or bruised. The Potatoes from which they are to be taken should be exposed to the air and some light; no germs should be taken off previously, second shoots being useless. They should be planted with a dibble, after ploughing or digging about the middle of May, when night frost are no longer to be feared. The planting requires no particular care beyond avoiding breaking them. The discoverer of this plan claims the following advantages for it:—1. It accelerates the growths allowing two crops to be taken from the same ground. 2. The Potato deprived of its shoots is still available as food, while the cost of seed is greatly reduced, Potatoes averaging above ten shoots, and one only being required for each plant.—GUSTAVE KÜSTER, in "Field."

QUESTIONS AND ANSWERS.

Double White Violets.—I should be grateful for advice as to the management of the double white Violet, which does not succeed well with me. There is ample promise of flowers, but the result is miserable abortions. I may add that the roots have been allowed to run together until they form quite a mat.—C. R.

Growing the Moccasin-flower.—I have several times tried to grow this so well drawn in THE GARDEN lately by Mrs. Duffield, among my hardy flowers and failed: unfortunately I have no peat, nor is there any near. Can you suggest any help, as I should like to establish such a noble hardy Orchid?—J. H. H. —[Plant at the foot of a north wall in a moist border, using much decomposed vegetable soil with the loam. If there be a little shelter from low bushes, &c., on each side all the better. If you have the opportunity, try it also in a moist spot among bushes. The foliage suffers from the dust and parched air too frequent near bare borders, wide gravel walks, &c. Strong and healthy roots should be secured.—V.]

Insects in Vineries.—I find the enclosed insects to be very troublesome in our Vineries. I have picked off sixteen from the lower leaves in a ten-light house in less than half-an-hour. They first appeared on the young fronds of *Adiantums*. My plan is to catch them and kill them. I find bunches of Moss to be good traps for them; they get into them when daylight appears. What is the name of this insect, and how can I best get rid of it?—SUBSCRIBER. [Its name is *Otiorthochus subvatus*—hard to pick, and look for the larvae in the soil in autumn and winter.]

Evergreen Oak Insects.—The leaves of our Evergreen Oaks are very much injured by the grub of some insect, which does its work in the same way as the Celery fly. Young healthy trees 6 ft. or 8 ft. high planted about five years ago are disfigured by it. It could of course be checked on a small scale in the same way as we do the Celery fly, i.e. by picking off the affected leaves or bruising the grubs in them, but to do that in the case of a number of trees would be rather a tedious task.—JOHN MATHERSON, *Addington, Windsor*. [The Evergreen Oak leaves, of which some were sent along with this communication, are ruined by the larva of a small moth named *Lithocolletis messaniella*: the perfect moth will appear in May. Common Oak leaves are ruined by another species of *Lithocolletis*—several species feed on them. Of course nothing can be done for them now, nor indeed is it easy to suggest any better plan of dealing with them than that mentioned by your correspondent.—A. M.]

Grass-destroying Grubs.—During the past week or two I have noticed great numbers of grubs on Primrose Hill. They seem to come out of the ground, and have totally destroyed the Grass on great patches of the hill. In many places the paths are covered with them, and they lie in handfuls in the gutters. I send you specimens collected this morning, and shall be glad if you can inform what they are, and whether there is any preventive for them, as they are like a plague in the district. I may add that last autumn I noticed vast numbers of the flies commonly called daddy long-legs about the same spots. Are these the producers of the grubs?—R. J. G. READ, 13, *Bernard Street, Royal's Park*. [The grubs sent are those of the dually long-legs; they are very destructive to lawns and Grass plots. Try watering the turf with a mixture of corrosive sublimate dissolved in muriatic acid in the proportion of 1 oz. to ½ pint of acid, and the addition of 80 gallons of water.—J. B.]

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWERS OF THE WESTERN PYRENEES.

THE sulphur-coloured variety of *Narcissus Bulbocodium* (see p. 246), mentioned as having been received from Mr. Barr, is the common form of the species in the Western Pyrenees. It is frequently met with both on the sandy coasts of the Bay of Biscay and on the hill-sides and slopes of the mountains, always occurring in little social groups or colonies, as is the manner of many *Narcissi*. The first place in which I found it was on the high sandy bluffs near the lighthouse of Biarritz, growing in beautiful co-partnership with *Lithospermum prostratum*, the sweet flowers of *Daphne Cneorum*, and the lilac *Ixia Bulbocodium*, with flowers as large as those of *Crocuses*, and abundant there. In form and in colour this foreground scene was one of matchless beauty. The distant landscape, too, was worthy of such a foreground: on the right was the Bay of Biscay, with the rocks of San Sebastian and the Spanish coast to the south; in front was the valley of the Adour with the old city of Bayonne, and behind that was the great chain of snowy Pyrenees stretching away to the extreme east. There is a wide extent of unenclosed common land in the neighbourhood of Biarritz, which is clothed with a vegetation of great interest and beauty. *Osmunda regalis* is the Fern of the district, and tangled with it grow *Erica mediterranea*, *ciliaris*, and *vagans*. *Cistus alyssoides* and other shrubby sorts may likewise be found here, and also many of the smaller genera of *Fumana* and *Helianthemum*. *Genista* and *Spartium*, and small leguminous shrubs, too, are beautifully represented. The whole of this open country is swept so severely by the winds of the Atlantic that no trees can attain any size. In order to see such plants as require shelter I should recommend a visit to be paid to the little French watering place called Cambo, which is ten or twelve miles from Biarritz, nestled amid the protecting shoulders of the Pyrenees. The country there is abundantly wooded, and affords a good example of the flora of the western Pyrenees; under the forest trees grow *Box* and *Mediterranean Heath*, and sheets of *Hepaticas* colour the hill-sides. They are singularly enough all white, or nearly so. Conditions of soil and climate seem to influence *Hepaticas* in a remarkable degree. In some places they are exclusively blue, in others I am told all red, while here they are invariably of a pale type, very large and fine, but never bright blue, which is the usual colour of the *Hepatica*. Growing parasitically on the roots of *Poplars*, which fringe the sides of streams, may be seen *Lathræa clandestina*, a remarkable plant which at once attracts attention on account of its large purple ringent flowers and thick masses of fleshy growth. Then there is *Helleborus thalictroides*, a plant of great delicacy and beautiful habit, so attractive that I wonder it is not more common than it is in English gardens. *Daffodils* are very numerous in the South of France, but they vary in form and size more than is common with us; they differ, and that greatly in the length and form of the tube, some being quite narrow and abruptly truncated, others scalloped, or broad, or fringed. This is so remarkable, especially among the crevices of the rocky hill above Bagnères de Bigorre, as to arrest the attention of the most indifferent observer. *Ranonda pyrenaica* is found in many of the side valleys; it grows to a size and beauty which our garden specimens do not approach; it seems to like to hang on the under sides of damp rocks, and the leaves in such situations measure fully 8 in. or 10 in. across, and are covered over with long woolly felt. Higher up, as one approaches the snowy ranges, *Saxifraga oppositifolia* attains a size and beauty which has induced English nurserymen to give it the rank of a separate variety; it is called *S. oppositifolia pyrenaica*. In size and colour of the flowers it is worth a journey to see. The foregoing remarks refer entirely to the Western Pyrenees, the Eastern or Mediterranean side of the chain have, I need scarcely say, a different climate, different conditions, and a different flora. J. D. LEWELYN.

NOTES OF THE WEEK.

GRAFTED CACTI.—At the meeting of the Royal Horticultural Society on the 18th inst., Mr. Croucher exhibited an interesting collection of grafted Cacti; among them were *Echinocacti* and silvery-spined *Mammillarias* grafted on stems of a *Cereus*, a few inches high, and thus situated they looked much better than when their bases are discoloured, as they usually are through contact with moist soil. One of the most singular examples was a small branched plant of *Pereskia aculeata*, on which had been grafted plants of *Cereus peruvianus monstrosus*, *Opuntia microdasys*, *O. clavarioides*, *O. ovata*, and also two species of *Rhipsalis*, namely, *R. funalis* and *R. paradoxa*. It is interesting to know that almost any of the large-growing species of *Cereus* may be studded with *Mammillarias*, small-growing *Opuntias*, Rat-tailed *Cereus*, or the pendulous Mistletoe-like *Rhipsalis*, and that thus treated they are much more interesting than when grown in the ordinary way.—B.

PITIOSPORUM UNULATUM.—We have examples of this in the conservatory and also out-of-doors, and it may be interesting to know that it is well worth growing in both positions, as its flowers, which are white, are as sweetly scented as those of the *Stephanotis* or *Orange blossom*. They are produced in clusters on the points of the shoots, and are useful in a cut state. The plants of it which we have under glass have been blooming since January, and those out-of-doors will be in flower in a few days. They grow freely in common garden soil, and beyond a little water now and then they need no attention, as they are not subject to insects or liable to disease of any kind.—A NORTHERN GARDENER.

MYRSIPHYLLUM ASPARAGOIDES.—This plant, which is a native of the Cape of Good Hope, though seldom well grown in English gardens, is nevertheless one of the most useful twining plants which we possess. It should be grown in an intermediate-house, and be allowed to twine up pieces of string or matting strained closely under the roof. In America it is extensively grown in this way and sold by the florists at so much per yard, string, foliage, and flowers all being cut together. It is used in bouquets and for festoons and vases, purposes for which it is admirably adapted, its bright glossy leaves and small, pearl-like, nodding flowers possessing both a light and elegant appearance. For twining round *épergues* and other flower-stands it will be found very useful, and both foliage and flowers last in a cut state for a considerable length of time. Several good plants of it may now be seen in the Pine-apple nursery grown in the way just described. They appear to grow rapidly and are now flowering freely.—S. C.

NEW LARGE-FLOWERED MIGNONETTE.—At the Horticultural Exhibition at South Kensington on Wednesday last, Messrs. Brookes & Gallop, of Western Road, Brighton, exhibited some remarkable examples of Miles' Hybrid Spiral Mignonette, a robust and floriferous variety, and certainly the largest-flowered form that I have yet seen, producing as it does erect, columnar spikes, 6 in. or more of which are covered with fully-expanded blossoms. As a vigorous, free-growing variety for ordinary decorative purposes or for market, this Mignonette should soon become popular, seeing that it is as fragrant as the older forms, and that it possesses a very distinctive appearance.—B.

BOUARDIAS AT CLAPTON.—A house in Messrs. Lew's nursery, containing many thousands of plants of *Bouvardia jasminiflora*, will soon be a sight worth seeing. Many of the blossoms have already expanded, and multitudes more are fast opening. These plants were struck from cuttings obtained when the last of the autumn-flowering plants were stopped; they were inserted in 3-in. pots, and when well rooted were shifted into 5 in. and 6 in. ones, in which they are allowed to flower. Their shoots were stopped four times during the autumn and winter, and plants treated in this manner become dwarf and bushy, and bear abundance of healthy bright green leaves and a profusion of fragrant blossoms that forcibly remind one of those of the white *Jasmine*.—C.

PUSCHKINIA SCILLOIDES.—For several years past three distinct plants bearing this name may have been met with in establishments in which bulbous and other hardy plants are grown, and probably some may have been in doubt as to which of them was the true *Puschkinia scilloides*. Specimens of the three plants in question have recently been sent to Kew for Mr. Baker's inspection, and his opinion is that the true *Puschkinia scilloides* is the smallest of the three usually met with under that name. The other two he believes to be *Puschkinia sicula*. To this decision some may take exception, inasmuch as although both of the plants in question produce similar *Allium*-like flowers, yet they appear to me to be distinct—at all events sufficiently so for horticultural purposes. One of these plants bears flowers on short pedicels in spikes, and has a broad marking of

blue down the centre of each petal, while the other has its flowers borne on long pedicels in an umbel, and has a distinct marking of green down each division of the flower.—T. S.

PERPETUAL CARNATIONS.—Throughout the winter two or three plants of perpetual-flowering Carnations have kept up a constant succession of bloom in boxes outside my windows, which have a southern exposure; they have not had the slightest protection. In the open border they generally rot off in winter, but the thorough drainage of the window-boxes suits them admirably.—SALMONICEPS.

DENDROBIUM CRASSINODE.—Several hundred plants of this beautiful Orchid, growing on wooden blocks suspended from the roof of one of the houses in the Clapton nursery, are now finely in flower. The blooms are large and well coloured, and the plants being hung in a row along the house, have an attractive appearance.—S.

AMARYLLIS BEAUTY OF REIGATE.—This is one of the most useful Amaryllises in cultivation, inasmuch as its rich crimson flowers, in addition to being very effective, are deliciously fragrant. In Messrs. Rollisson's nursery there are now plants of it bearing flower-spikes, each of which is surmounted by from six to ten fully expanded blossoms, and although not so large as the flowers of many other varieties, Beauty of Reigate well deserves a place in every collection.—S.

MASDEVALLIA VEITCHI AND LINDENI.—These are now flowering freely in Messrs. Veitch's nursery at Chelsea, and the blossoms, owing to their being subjected to more sunlight than they lately have been, are brighter in colour than they were a few weeks ago. The singular orange-scarlet flowers of the former are not less interesting, though, perhaps, less showy than the rosy-pink blossoms of the latter, but both rank amongst the best of the Masdevallias.—C. S.

ERIOSTEMON MYOPOROIDES HARDY IN THE ISLE OF WIGHT.—In Colonel Harcourt's garden at St. Clare, in this parish, there is a plant of *Eriostemon myoporoides*, which is just now beautifully in blossom. Mr. Meehan tells me that it has been quite hardy at St. Clare in the open ground for several years. It is so very pretty that it is worthy of a trial in other places besides this.—HENRY EWBANK, *St. John's, Ryde.*

CRIMSON-SCARLET DOUBLE-FLOWERED PEACH.—A plant of this brilliant variety of double-flowered Peach, growing in Mr. Parker's nursery at Tooting, is now finely in bloom and remarkably handsome. Either in shrubberies or in isolated positions on lawns such trees as this can scarcely be too largely planted, as, in addition to the fine display which the flowers make when on the plants, they are also strikingly effective when cut and associated with other flowers in vases for indoor decoration. They put one in mind of the richly-coloured blossoms of *Cydonia cardinalis*; but the latter are not so valuable in a cut state.—C.

MAGNOLIAS ROUND LONDON.—Owing to the mild season which we have experienced, Magnolias are everywhere unusually floriferous, and the few days' sun which we have lately had have been the means of inducing thousands of their—in some instances—deliciously scented blossoms to expand. Though not of great value in the market in a cut state at this season, owing to the immense quantities of other flowers now obtainable, if good plants of *Magnolia conspicua* could be grown in pots and brought on in a warm temperature, so as to be in bloom at Easter, when white flowers are in great demand, they would no doubt meet with a ready sale. In cool conservatories, too, such plants, when in blossom, would form striking objects.—W.

MARKET GARDEN PRODUCE.—The exhibition of this at South Kensington the other day having proved in all respects successful, it has been proposed to hold a similar exhibition at the same place at an early date, in order to afford market gardeners an opportunity of exhibiting what they grow. This may be desirable; but at the same time let us hope that good collections of imported vegetables and salad material as sent to our markets by the French and Channel Island growers will also be forthcoming, for the sake of contrast.

SALE OF EXHIBITION PLANTS.—Mr. J. Cypher's collection of exhibition, stove, and greenhouse plants was sold by Messrs. Protheroe & Morris, at Cheltenham, on the 11th and 12th inst., and, a large number of buyers being present, there was a brisk competition. Specimen *Azalea* realised from 7 guineas to 10 guineas each; *Hedera tulipifera*, 4½ ft. by 5 ft., realised 21 guineas; *Gleichenias* also sold well, a plant of *G. Mendelli* brought £21; and *Davallia Mooreana* fetched £6 15s. Amongst Palms, *Cocos Weddelliana* realised 19 guineas; *Pritchardia pacifica*, 16 guineas; *Croton Weismanni*, 8 guineas; a moderate-sized *Anthurium Scherzerianum majus*, 16 guineas; a plant of *Erica Cavendishi*, 7 guineas; and several other species realised 5 and 6 guineas each.

VINES UNDER BLUE GLASS.

SEEING in Dundee papers an account of some experiments that had been made with blue glass in Vineries, lately erected for Mr. Spence of that town, we wrote to Mr. Lawrie, of 16, Seafield Road, Dundee, under whose direction they have been conducted, and the following is his reply:—It is as yet premature to speak definitely as to the results likely to be arrived at as regards this experiment, for these reasons; first, because the Vines were only struck from eyes about a year ago; and secondly, out of the eight weeks since I commenced to force, we have only had a fortnight of sunshine, and from observations made, it is evident that the whole of the success lies in having an abundant supply of the blue sunray. In the first place I shall say a word or two about the Vines. We took two Vineries of equal size in every respect, filled them with the proper soil for Vine-growing, got good, healthy plants from Mr. Thomson, of Clovenfords, planted both houses the same day (January 13), pruned them and allowed them to settle in the soil till February 8, on which date they were watered and a gentle heat of 45° applied. As I have just stated the two houses are of equal size, and both have the same advantage as regards sun light, and the temperature of both strictly the same, the only difference between the two being that the one is furnished with strips of blue glass and the other is glazed with ordinary white glass only. Now for the results so far as the experiment has gone. At the end of the first four weeks, that is on March 8, the Vines had made 16 in. of growth under the blue, and only 4 in. under the white glass. On the 9th inst. the Vines under the blue glass measured 3 ft. 4 in., and under the white 2 ft. 4 in., the two being equal in strength, but showing that the absence of the sun had retarded the progress of those under the blue glass to a greater extent than it had done those under the white glass. All the plants, such as *Camellias* and *Fuchsias*, are vigorous and healthy, although some of them were rather sickly when the experiment was commenced. Wishing also to test the effect of blue light upon vegetables, we planted a few early Potatoes in each house. They were planted on the same date as the Vines, and without any other heat than the atmospheric heat of the houses, the result to-day (April 10) is six of the Potatoes from under the blue glass weighed 11 oz., and six from under the white weighed only 5 oz.

Double Daffodils.—How very inferior these and double Snow-drops are to the single forms! in fact they are almost ugly. In Ireland (I am only acquainted with the country lying north of Dublin) I have never seen the common single Daffodil, though I have seen *Narcissus minor* and *N. minimus*. Is it something in the soil that makes the bulbs throw up double flowers? It may be safely laid down in an æsthetic, if not in a horticultural sense, that no flower is improved by doubling; the elasticity of form is lost. Even in a horticultural aspect no flower gains by doubling (except what it gains in colour and perfume) save that double, and therefore barren flowers last longer. Who cares for a double Lily? Who would prolong the blooming of the exquisite Irises at the expense of doubling?—SALMONICEPS.

DEATH OF M. RIVIÈRE.—This well-known horticulturist, for many years chief gardener at the Luxembourg in Paris, died last Saturday evening. He was buried on Tuesday, followed to the grave by between 400 and 500 of the horticulturists of Paris. Mr. Rivière, who died comparatively young, was a most accomplished gardener, and well able to convey his knowledge to others. His lectures on fruit tree culture at the Luxembourg were numerously attended and very useful. For the past ten years he has been at work on a richly-illustrated book on fruit culture. The war and other causes have prevented its publication up to the present time; it is to be hoped his sons will issue the work, which is certain to be a valuable one. He was also for some time before his death at work on a book on Bamboo plants, which of late years have attracted much attention both in France and Algeria. He possessed much botanical as well as horticultural knowledge, and was particularly well acquainted with Orchid culture. He was the first to raise from seed hybrid Orchids in France. He was also the Director of the Jardin du Hamma in Algeria, of which his son is now the Sub-director. His collection of Bromeliads in the Luxembourg was one of the richest existing. His death before his work was done is a great loss to French horticulture. He was at all times most kind to others—most amiable to strangers. We cannot entertain a better wish for the future of our botanical and national gardens than that they may be directed by men as able and as good as Auguste Rivière.

Kalmias Best on the Margins of Lakes.—These are often met with in hot sunny situations, and in dry stony soils, where the roots cannot obtain sufficient moisture to keep the foliage from becoming browned by the sun. They succeed much better when planted by the sides of lakes or in similar moist positions where they also often receive partial shade. Both *K. myrtifolia* and *K. latifolia* may be safely planted in such situations, and neither rabbits nor hares will harm them. They thrive best in moist sandy loam.—S.

STATE OF VEGETATION IN MARCH.*

THE early part of March was favourable for gardening operations, being for the most part dry and cool, and without much of the wind for which March is proverbial. Towards the end, however, rain fell in abundance, and scarcely ceased during five consecutive days, viz., from the 23rd till the 28th. The month set in with a slight snow-fall, and frost has been prevalent throughout it; the temperature in general being rather below the average; vegetation is therefore backward. The genial weather which we had early in February brought it forward rapidly, but March left it nearly at a standstill. Many of the open-air plants reported to be in bloom in February have since fallen back, and although others have come into flower, few of them show that vigour which they generally do at this season. Early in February Hazels and Filberts were loaded with long, drooping, yellow catkins, which, however, got browned by frost about the end of that month and beginning of March; similar injury was also sustained by the drooping catkins of *Garrya elliptica*, while the Alder, particularly *Alnus cordifolia*, which was richly covered during the

month with its brownish-yellow catkins, did not suffer in the least, notwithstanding the frost to which they were exposed. Early *Rhododendron* blossoms, particularly those of *R. præcox*, *R. atrovirens*, and *R. dahuricum*, were all more or less injured; those of *Rhododendron Nebleanum* and other early, large-flowering hybrids, have been scarce this spring, owing to the buds not having been properly matured during the long, wet, sunless autumn which we had. The branches of *Thujas*, *Bietas*, and other allied Coniferous shrubs, are much browned, similar to what took place in April last year, and which resulted in the total destruction of some and the disfigurement of others. The leaves of many kinds of *Pinus* have also become very brown, such as those of *patula*, *densiflora*, *conserta*, *Fremontiana*, *Britia*, *muricata*, *tuberculata*, *Benthamiana*, as well as those on some specimens of *Laricio* and even the Scotch Fir. This result is evidently brought about by the long, moist autumn and winter which we have had, succeeded by a lengthened although not very severe frost, and afterwards followed by a few days of hot sun acting upon unripened wood. Early fruit tree blossoms on walls have also suffered from the frost; owing, however, to the rather unusual number of buds produced, a moderate quantity may yet be saved, although it is feared that the effects of the long, sunless, wet autumn will operate against a proper setting of the fruit. Many early spring bulbs, particularly those growing in low situations, have rotted in the ground, and even the printed tallies used for naming open-air plants have, in some cases, been rendered wholly illegible from excessive damp, a circumstance which has not occurred to the same extent at any former period. On the last day of February fifty species of plants were counted in flower in the rock garden; many of these have since suffered from frost. On March 31 seventy-five species and varieties were counted in bloom, the most conspicuous being *Andromeda florihunda*, *Bulbocodium vernum*, *Corydalis angustifolia*, *Dendia Epipactis*, *Draba aizoides* and *cuspidata*, *Epigaea repens*, *Erica carnea*, *E. carnea alba*, *E. hibernica alba*, *E. h. nana*, *Erythronium Nuttallianum*, *Gagea lutea*, *Helleborus ilicifolius*, *Hepatica angulosa*, the varieties of *H. triloba*, *Iris reticulata*, *Merendera caucasica*, *Omphalodes verna*, *Primula denticulata*, *marginata*, *Palinuri*, *purpurea*, and *viscosa*; *Saxifraga crassifolia*, *grandiflora*, and *bryoides*; *Scilla bifolia*, *S. b. alba*, *S. taurica*, *Sisyrinchium grandiflorum album*,

Narcissus nanus, and *N. pumilus*. During March, the thermometer was twenty times at or below the freezing point (indicating collectively 130°, while 98° were registered during the corresponding month last year), the lowest markings being on the mornings of the 1st, 4th, 19th, 20th, 21st, and 22nd, when 17°, 23°, 20°, 18°, 23°, and 24° were respectively indicated. The highest morning temperatures were on the 11th, 14th, 27th, 28th, 29th, and 31st, when 41°, 41°, 36°, 37°, 37°, and 42° were registered. Although 492° of frost have been recorded during the past five months, particularly in the neighbourhood of Edinburgh, it has never been at any one time of such intensity as to produce strong-bearing ice.

The scarcity of vegetables for spring planting, such as early Cabbages, Savoys, and Greens, is something quite unprecedented about Edinburgh, cart-loads being usually seen in our markets at this time. The drought which immediately followed the sowing last year prevented a healthy germination, and was afterwards followed by an unusually wet autumn, and that at a time when the plants were weak. To this, and the changeable weather experienced during winter, may be attributed their scarcity. Fortunate holders are receiving high prices for them. The scarcity seems to be general throughout Scotland, as few yet arrive by railway.

Rhus vernix.

Centaurea Clementei.—

This fine, silver-grey-leaved plant forms an excellent companion to the *Acanthuses*, the deep green of which helps to enhance the peculiar beauty of the *Centaurea*. Here they are both perfectly hardy, some fine clumps of them that have stood several winters being now in beautiful condition. I consider this *Centaurea* preferable to the *Artichecke*, which is sometimes recommended as an early, grey-leaved plant, as it is of better habit and retains its foliage throughout the season. We usually raise it annually from seed as small plants are those most serviceable for edging sub-tropical or other beds, and when too large for that purpose, they are transferred to shrubbery or woodland borders or planted out singly on Grass. The blossoms are best picked off, as they rather detract from than add to the beauty of the plant, the energies of which being then concentrated on leaf growth. This class of plants commends themselves strongly to amateurs with limited glass accommodation, as by a judicious admixture of

such plants, the requisite number of tender subjects for furnishing flower beds may be reduced to a minimum without loss as regards the general effect.—J. GROOM, *Henham*.

THE AILANTUS-LEAVED SUMACH.

(RHUS VERNIX).

ALL the species and varieties of Sumach are more or less graceful in habit; but that of which the annexed figure is a representation is one of the very best and most distinct for decorative purposes, and especially for planting in sheltered positions on lawns, on which it forms during the summer months an effective fine-foliaged shrub, its fresh green leaves rivalling in beauty even those of the *Ailantus* itself. It grows freely in almost any deep, well-enriched garden soil, and attains a height of from 3 ft. to 6 ft. Like many other species of *Rhus*, it may be increased by means of cuttings made of pieces of the roots inserted in a genial bottom-heat, and young plants obtained in this manner are preferable, inasmuch as their growth is much more rapid than that of older plants. This

* Read by Mr. J. M'Nab before the Botanical Society of Edinburgh, April 12, 1877.

Sumach is seldom seen in cultivation in this country, although it is an old Linnæan species, and one which is frequently seen in Parisian parks and gardens. Its synonyms are *R. vernicifolia*, *R. juglandifolia*, and *R. Wallichii*. B.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 298).

Cuckoo Buds and Flowers.

(1) *Song of Spring.*

When Daisies pied, and Violets blue,
And Lady-smocks all silver-white,
And Cuckoo-buds of yellow hue
Do paint the meadows with delight.

Love's Labour's Lost, act v., sc. 2.

(2) *Cornelia.*

He was met even now
As mad as the vexed sea—singing aloud;
Crown'd with rank Fumitory and farrow weeds,
With Burdocks, Hemlock, Nettles, Cuckoo-flowers,
Darnel, and all the idle weeds that grow
In our sustaining corn.

King Lear, act iv., sc. 4.

There is a difficulty in deciding what flower Shakespeare meant by Cuckoo-buds. We now always give the name to the Meadow Cress (*Cardamine pratensis*), but it cannot be that in either of these passages, because that flower is mentioned under its other name of Lady-smocks in the previous line (No. 1), nor is it "of yellow hue;" nor does it grow among Corn, as described in No. 2. Many plants have been suggested, but I think the Buttercup, as suggested by Dr. Prior, will best meet the requirements.

Currants.

Clown. What am I to bring for our shearing' feast? Three pounds of sugar, five pounds of Currants.

Winter's Tale, act iv., sc. 2.

These are the Currants of commerce, the fruit of the *Vitis Corinthiaca*, whence the fruit has derived its name of Corans, or Currants. The English Currants are of an entirely different family.

Cypress.

(1) *Suffolk.* Then sweetest shade, a grove of Cypress trees!

2nd Henry VI., act iii., sc. 2.

(2) *Clown.* In sad Cypress let me be laid.—*Twelfth Night*, act ii., sc. 1.

(3) *Amidius.* I am attended at the Cypress grove.

Coriolanus, act i., sc. 10.

(4) *Gremio.* In ivory coffers I have stuffed my crowns,
In Cypress chests my arras.

Taming of Shrew, act ii., sc. 1.

The Cypress (*Cupressus sempervirens*), originally a native of Mount Taurus, is found abundantly through all the south of Europe, and is said to derive its name from the Island of Cyprus. It was introduced into England many years before Shakespeare's time, but is always associated in the old authors with funerals and churchyards: so that Spenser calls it the "Cypress funeral." "In the Arundel MS. 42 may be found an alphabet of plants. . . . The author mentions his garden 'by Stebenhythe by syde London,' and relates that he brought a bough of Cypress with its Apples from Bristol 'into Est-britzlond,' fresh in September, to show that it might be propagated by slips."—"Promptorium parvulorum," app. 67). It is an ornamental evergreen, but stiff in its growth till it becomes of a good age; and for garden purposes the European plant is becoming replaced by the richer forms from Asia and North America, such as *C. Lawsoniana*, *macrocarpa*, *Lambertiana*, and others.

Daffodils.*

(1) *Autolycus.* When Daffodils begin to peer,

With heigh! the doxy o'er the dale,
Why, then comes in the sweet of the year.

Winter's Tale, act iv., sc. 3.

(2) *Perdita.*

Daffodils
That come before the swallow dares, and take
The winds of March with beauty.

Ibid., act iv., sc. 3.

* This account of the Daffodil, and the accounts of some other flowers, I have taken from a paper by myself on the common English names of plants read to the Bath Field Club in 1870, and afterward privately printed.—H. N. B.

Of all English plants there have been none in such constant favour as the Daffodil, whether known by its classical name of *Narcissus*, or by its more popular names of Daffodil, Daffadownilly, and Jonquil. The name of *Narcissus* it gets from being supposed to be the same as the plant so named by the Greeks first and the Romans afterwards. It is a question whether the plants are the same, and I believe most authors think they are not; but I have never been able to see very good reasons for their doubts. The name Jonquil comes corrupted through the French, from "juncifolius" or "rush-leaf," and is properly restricted to those species of the family which have rushy leaves. "Daffodil" is commonly said to be a corruption of *Asphodel*, with which plant it was confused (as it is in Lyte's "Herbal,") but Lady Wilkinson says very positively that "it is simply the old English word 'affodyle,' which signifies 'that which cometh early.'" "Daffadownilly," again is supposed to be but a playful corruption of "Daffodil," but Dr. Prior argues (and he is a very reliable authority) that it is, rather a corruption of "Saffron Lily." Daffadownilly is not used by Shakespeare, but it is used by his contemporaries, as by H. Constable, who died in 1604:—

Diaphenia, like the Daffadownilly,
White as the sun, fair as the Lily,
Heigh, ho! how I do love thee!

But however it derived its pretty names, it was the favourite flower of our ancestors as a garden flower, and especially as the flower for making garlands, a custom very much more common then than it is now. It was the favourite of all English poets from the time of Shakespeare to our own time. Shakespeare must have had a special affection for it, for in all his descriptions there is none prettier or more suggestive than *Perdita's* short but charming description of the Daffodil (No. 2). A small volume might be filled with the many poetical descriptions of this "delectable and sweet-smelling flower," but there are two especially which are almost classical, and which can never be omitted, and which will bear repetition, however well we know them. There are Herrick's well-known lines:—

Fair Daffodils, we weep to see
You haste away so soon,
As yet the early-rising sun
Has not attained his noon;
Stay, stay,
Until the hastening day
Has run
But to the even-song;
And having prayed together, we
Will go with you along.
We have short time to stay as you,
We have as short a spring,
As quick a growth to meet decay,
As you or anything.
We die,
As your hours do, and dry
Away,
Like to the summer's rain,
Or as the pearls of morning dew,
Ne'er to be found again.

And there are Keats' well-known and beautiful lines which bring down the praises of the Daffodil to our own day. He says:—

A thing of beauty is a joy for ever,
Its loveliness increases, it will never
Pass into nothingness. . . .
In spite of all
Some shape of beauty moves away the pale
From our dark spirits. Such the sun, the moon,
Trees old and young, sprouting a shady boon
For simple sheep; and such are Daffodils
With the green world they live in.

But it is time to come to prose. The Daffodil of Shakespeare is the wild Daffodil (*Narcissus Pseudo-Narcissus*) that is found in abundance in many parts of England. This is the true English Daffodil, and there is only one other species that is truly native—the *N. biflorus*, chiefly found in Devonshire. But long before Shakespeare's time a vast number had been introduced from different parts of Europe, so that Gerard was able to describe twenty-four different species, and had "them all and every of them in our London gardens in great abundance." The family, as at present arranged by Mr.

J. G. Baker, of the Kew Herbarium, consists of twenty-one species, with several sub-species and varieties; all of these should be grown. They are all, with the exception of the Algerian species, which almost defy cultivation in England, most easy of cultivation—"Magnâ curâ non indigent Narcissi." They only require after the first planting to be let alone, and then they will give us their graceful flowers in varied beauty from February to May. The first will usually be the grand *N. maximus*, which may be called the King of Daffodils, though some authors have given to it a still more illustrious name. The Rose of Sharon was the large yellow Narcissus, common in Palestine and the East generally, of which Mahomet said—"He that has two cakes of bread, let him sell one of them for some flower of the Narcissus, for bread is the food of the body, but Narcissus is the food of the soul." From the grand leaders of the tribe we shall be led through the Hoop-petticoats, the many-flowered Tazettas, and the sweet Jonquils, till we end the Narcissus season with the Poets' Narcissus, certainly one of the most graceful flowers that grows, and of a peculiar fragrance that no other flower has; so beautiful is it that even Dr. Forbes Watson's description of it is scarcely too glowing:—"In its general expression the Poets' Narcissus seems a type of maiden purity and beauty, yet warmed by a love-breathing fragrance; and yet what innocence in the large soft eye, which few can rival amongst the whole tribe of flowers. The narrow, yet vivid fringe of red, so clearly seen amidst the whiteness, suggests again the idea of purity, gushing passion—purity with a heart which can kindle into fire."

Daisies.

- (1) *Song of Spring.* When Daisies pied and Violets, &c.
Love's Labour Lost, act iii., sc. 2 (See Cuckoo-buds).
- (2) *Lucius.* Let us
Find out the prettiest Daisied plot we can,
And make him with our pikes and partizans
A grave. *Cymbeline*, act iv., sc. 2.
- (3) *Ophelia.* There's a Daisy. *Hamlet*, act iv., sc. 5.
- (4) *Queen.* Therewith fantastic garlands did she make
Of Crow-flowers, Nettles, Daisies, and Long Purples.
Hamlet, act iv., sc. 7.
- (5) Without the bed her other faire hand was
On the green coverlet, whose perfect white
Showed like an April Daisy on the Grass.
Rape of Lucrece.

The Daisy of Shakespeare is not such an illustrious flower as the Daisy of Chaucer. With Chaucer the love of the Daisy amounted almost to an idolatry. He celebrates it in many of his poems and at great length, but here I can only find room for these few lines.

Of all the flowers in the mede,
Then love I most those flowers white and redde,
Such that men callen Daisies in our town—
To them I have so great affection
As I said erst, when comen is the Maye
That in my bedde there dawneth me no daie,
That I n'am up and walking in the mede
To see this flowre against the sunnâ sprede,
When it upriseth early by the morrow,
That blessed sight softeneth all my sorrow, &c.

As a garden flower the Daisy is not to be despised. We have the double Daisies of many colours, and the curious Hen-and-Chickens, or Childing Daisy, and these were ornaments of gardens in Shakespeare's time also. They require good soil and frequent division to keep them in beauty. There are many interesting points connected with the history, poetry, and botany of the Daisy, which I do not mention here, but for which I may refer to my paper on the Daisy, read in January, 1874, to the Bath Field Club, and published the following month in THE GARDEN.

Damsons (see Plums).

Darnel.

- (1) *Cordelia.* Darnel and all the idle weeds that grow
In our sustaining corn.
King Lear, act iv., sc. 4. (See Cuckoo-flowers).
- (2) *Burgundy.* Her fallow lees,
The Darnel, Hemlock, and rank Fumitory
Dost root upon.
Henry V., act v., sc. 2.

Virgil, in his Fifth Eclogne, says:—

Grandia sæpe quibus mandavimus hordea solcis
Infelix lolium et steriles dominantur avenæ.

Thus translated by Thomas Newton, 1587—

Sometimes there sproutes abundant store
Of baggage, noisome weeds,
Burres, Breambles, Darnel, Cockle, Dawke,
Wild Oates, and choaking seedes.

And the same is repeated in the first Georgic, and in both places *lolium* is always translated Darnel, and so by common consent Darnel is identified with the *Lolium temulentum* or wild Rye-grass. But in Shakespeare's time Darnel, like Cockle (which see), was the general name for any hurtful weed. In the old translation of the Bible, the *Zizania*, which is now translated Tares, was translated Darnel, and Newton, writing in Shakespeare's time, says:—"Under the name of Cockle and Darnel is comprehended all vicious, noisom and unprofitable graine, encombring and hindring good corne." ("Herbal to the Bible"). The Darnel is not only injurious from choking the corn, but its seeds become mixed with the true Wheat, and so in Dorsetshire—and perhaps in other parts—it has the name of "Cheat" (Barnes' "Glossary"), from its false likeness to Wheat. It was this false likeness that got for it its bad character. "Darnell or Juray," says Lyte ("Herbal," 1578) "is a vitious graine that combereth or anyeth corne, especially Wheat, and in his knotten straw, blades, or leaves is like unto Wheate."

Dates.

- (1) *Clown.* I must have Saffron to colour my warden pies, Mace, Dates, none; that is out of my note.
Winter's Tale, act iv., sc. 2.
- (2) *Nurse.* They call for Dates and Quinces in the pastry.
Romeo and Juliet, act iv., sc. 4.
- (3) *Parolles.* Your Date is better in your pie and your porridge than in your check.
All's Well That Ends Well, act i., sc. 1.

The Date is the well-known fruit of the Date Palm (*Phoenix dactylifera*) the most northern of the Palms. The Date Palm grows over the whole of Southern Europe, North Africa, and South-eastern Asia; but it is not probable that Shakespeare ever saw the tree, though Lyte describes it, and Gerarde made many efforts to grow it; he tried to grow plants from the seed, "the which I have planted many times in my garden, and have grown to the height of three foot, but the first frost hath nipped them in such sort that they perished, notwithstanding mine industrie by covering them, or what else I could doe for their succour."

Dewberries.

Titania. Feed him with Apricocks and Dewberries.
Midsommer Night's Dream, act iii., sc. 1.

The Dewberry (*Rubus cæsius*) is a handsome fruit, very like the Blackberry, but coming earlier. It has a peculiar sub-acid flavour, which is much admired by some, as it must have been by Titania, who joins it with such fruits as Apricots, Grapes, Figs, and Mulberries. It may be readily distinguished from the Blackberry by the fruit being composed of a few larger drupes, and being covered with a glaucous bloom.

Docks.

- (1) *Burgundy.* And nothing teems
But hateful Docks, rough Thistles, Kecksies, Burs.
Henry V., act v., sc. 2.
- (2) *Antonio.* He'd sow it with Nettle seed,
Sebastian. Or Docks, or Mallows.
Tempest, act ii., sc. 1.

The Dock may be dismissed without further note or comment

Ebony.

- (1) *King.* The Ebon-coloured ink.
Love's Labour Lost, act i., sc. 1.
- (2) *King.* By heaven, thy love is black as Ebony.
Biron. Is Ebony like her? O wood divine!
A wife of such wood were felicity.
Ibid., act iv., sc. 3.
- (3) *Clown.* The clearstores towards the south north are as lustrous as
Ebony.
Twelfth Night, act iv., sc. 2.
- (4) *Pistol.* Rouse up revenge from Ebon dew.
2nd Henry IV., act ii., sc. 4.

The Ebony as a tree was unknown in England in the time of Shakespeare. The wood was introduced, and was the typical emblem of darkness. The timber is the produce of more than one species, but comes chiefly from *Diospyros Ebenum*, *Ebenaster*, *melanoxyton*, *Mabola*, &c. (Lindley), all natives of the East.

Eglantine.

- (1) *Oboron*. I know a bank whereon the wild Thyme blows,
Where Oxlips and the nodding Violet grows;
Quite over-canopied with lush Woodbine,
With sweet Musk-Roses, and with Eglantine.
Midsummer Night's Dream, act ii., sc. 1.
- (2) *Arrivagus*. Thou shalt not lack
The flower that's like thy face, pale Primrose; nor
The azure Harebell, like thy veins; no, nor
The leaf of Eglantine, whom not to shander,
Out-sweetened not thy breath.
Cymbeline, act iv., sc. 2.

If Shakespeare had only written these two passages they would sufficiently have told of his love for simple flowers. None but a dear lover of such flowers could have written these lines. There can be no doubt that the Eglantine in his time was the Sweet Brier. Gerarde so calls it, but makes some confusion—which it is not easy to explain—by saying that the flowers are white, whereas the flowers of the true Sweet Brier are pink. In the earlier poets the name seems to have been given to any wild Rose, and Milton certainly did not consider the Eglantine and the Sweet Brier to be identical. He says (L'Allegro):—

Through the Sweet Briar or the Vine,
Or the twisted Eglantine.

But Milton's knowledge of flowers was very limited. Herrick has some pretty lines on the flower, in which it seems most probable that he was referring to the Sweet Brier:—

From this bleeding hand of mine
Take this sprig of Eglantine,
Which, though sweet unto your smell,
Yet the fretful Briar will tell,
He who plucks the sweets shall prove
Many thorns to be in love.

It was thus the emblem of pleasure mixed with pain, and so its names pronounced it to be, it was either the Sweet Brier, or it was Eglantine, the thorny plant (Fr: *aignentier*). There was also an older name for the plant, of which I can give no explanation. It was called *Bedagar*. "*Bedagar dicitur gallici aignentier*."—John de Garlande. It is a native of Britain, but not very common, being chiefly confined to the South of England. I have found it on Maidenhead Thicket. As a garden plant it is desirable for the extremely delicate scent of its leaves, but the flower is not equal to others of the family. There is, however, a double-flowered variety which is handsome. The fruit is large, and of a deep red colour, and is said to be sometimes made into a preserve. In modern times this is seldom done, but it may have been common in Shakespeare's time, for Gerarde says quaintly—"The fruit when it is ripe maketh most pleasant meats and banqueting dishes, as tarts and such like, the making whereof I commit to the cunning cooke, and teeth to eat them in the rich man's mouth." Eglantine has a further interest in being one of the many thorny trees from which the sacred crown of thorns was supposed to be made—"And afterwards he was led into a garden of Cayphas, and there he was crowned with Eglantine."—Sir John Mandeville.

Elder.

- (1) *Arrivagus*. And let the stinking Elder, grief, entwine
His perishing root with the increasing Vine.
Cymbeline, act iv., sc. 2.
- (2) *Hostess*. What says my Esculapius? my Galen? my heart of
Elder?
Merry Wives, act ii., sc. 3.
- (3) *Saturninus*. Look for thy reward
Among the Nettles at the Elder tree,
This is the pit and this the Elder tree.
Titus Andronicus, act ii., sc. 4.
- (4) *Williams*. That's a perilous shot out of an Elder gun, that a poor
and private displeasure can do against a monarch.
Henry V., act iv., sc. 1.

- (5) *Holofernes*. Begin, sir, you are my Elder.
Biron. Well followed: Judas was hanged on an Elder.
Love's Labour Lost, act v., sc. 2.

There is, perhaps no tree round which so much of contradictory folk-lore has gathered as the Elder tree. With many it was simply "the shaking Elder," of which nothing but evil could be spoken. *Biron* (No. 5) only spoke the common mediæval notion that "Judas was hanged on an Elder;" and so firm was this belief that Sir John Mandeville was shown the identical tree at Jerusalem, "and faste by is zit, the Tree of Eldre that Judas henge him self npon, for despeyr that he hadde, when he solde and betrayed oure Lord." This was enough to give the tree a bad fame, which other things helped to confirm—the evil smell of its leaves, the heavy narcotic smell of its flowers, its hard and heartless wood, and the ugly drooping black fungis that is almost exclusively found on it, though it occurs also on the Elm, which was vulgarly called the Ear of Judas (*Hirneola auricula Judæ*). This was the bad character; but, on the other hand, there were many who could tell of its many virtues, so that in 1655 appeared a book entirely devoted to its praises. This was "the Anatomie of the Elder, translated from the Latin of Dr. Martin Blockwich by C. de Iryngio" (*i. e.*, Christ Irvine), a book that, in its Latin and English form, went through several editions. And this favourable estimate of the tree is very common in several parts of the Continent. In the south of Germany it is believed to drive away evil spirits, and the name "Holderstock" (Elder Stock) is a term of endearment given by a lover to his beloved, and is connected with Hulda, the old goddess of love, to whom the Elder tree was considered sacred. In Denmark and Norway it is held in like esteem, and in the Tyrol an "Elder bush, trained into the form of a cross, is planted on the new-made grave, and if it blossoms the soul of the person lying beneath it is happy." Nor must we pass by the high value that was placed on the wood both by the Jews and Greeks. It was the wood chiefly used for musical instruments, so that the name sambuke was applied to several very different instruments, from the fact that they were all made of Elder wood. The "sackbut," "dulcimer," and "pipe," of Daniel iii. are all connected together in this manner.

As a garden plant the common Elder is not admissible, though it forms a striking ornament in the wild hedgerows and copses, while its flowers yield the highly perfumed Elder-flower water, and its fruits give the Elder wine; but the tree runs into many varieties, several of which are very ornamental, the leaves being often very finely divided and jagged, and variegated both with golden and silver blotches. There is a handsome species from Canada (*Sambucus canadensis*) which is worth growing in shrubberies, as it produces its pure white flowers late in autumn.

Elm.

- (1) *Adriana*. Thou art an Elm, my husband, I a Vine,
Whose weakness, married to thy stronger state,
Makes me with thy strength to communicate.
Comedy of Errors, act ii., sc. 2.
- (2) *Titania*. The female Ivy so
Earrings the barky fingers of the Elm.
Midsummer Night's Dream, act iv., sc. 1.
- (3) *Poins*. Answer, thou dead Elm, answer!
2nd Henry IV., act ii., sc. 4.

Though Vineyards were more common in England in the sixteenth century than now, yet I can nowhere find that the Vines were ever trained, in the Italian fashion, to Elms or Poplars. Yet Shakespeare does not stand alone in thus speaking of the Elm in its connection with the Vine. Spenser speaks of "the Vine-prop Elme," and Milton—

"They led the Vine
To wed her Elm: she sponsed, about him twines
Her marriageable arms, and with her brings
Her dower, the adopted clusters, to adorn
His barren leaves.

But I should think that Shakespeare never saw a Vine trained to an Elm; he was simply copying from the classical writers.

H. N. ELLACOMBE.

(To be continued).

A REFLEXED SNOWDROP.

(*GALANTHUS Plicatus reflexus*).

THE variety here figured, although undoubtedly closely allied to the Crimean Snowdrop, may be readily distinguished by its outer petals being turned back like those of Cyclamens, Dodecatheons, and one or two species of Narcissus. Either Haworth or Herbert (I forget at the moment which) describes a *Galanthus reflexus*, but that appears to be a narrow-petalled, pallid, or yellowish-green marked form of the common Snowdrop, and, although named *G. reflexus*, the Rev. Harpur Crewe, who has lately re-discovered this variety (see THE GARDEN, p. 226), states that the outer petals droop as in the normal species. The plant we now figure bloomed in Mr. Barr's collection at Tooting during the first week in April, some time after a bed of *G. plicatus* had ceased flowering, but this difference in the season of blooming may possibly be due to late planting. About thirty flowers were expanded at the time when our sketch was made, all showing, without a single exception, the reflexed character very distinctly, and some unexpanded buds which were plucked from the plants at the same time expanded and assumed the same reflexed character indoors. B.

Galanthus plicatus reflexus.

THE FRUIT GARDEN.

VINE BORDERS.

THERE are few matters connected with horticulture of greater importance than the growth of the Vine; as to the merits of inside or outside borders, like most other matters of detail in the treatment of any important plant that will succeed under different conditions, there is certain to be different opinions. There is no doubt but that a great deal more assistance than the roots of Vines usually receive may be given to them when wholly confined to inside borders, and that when their every want is fully attended to at the exact time they require it, they may be kept going for a longer period with a greater amount of success than generally results from their roots being entirely outside the walls of the house in which they are grown. Yet those who advocate inside borders alone, even for early forcing, appear to ignore the fact that with the best possible treatment the Vines never attain half the strength, possess the lasting properties, or give general results equal to those that have their roots both inside and outside, where both alike receive the treatment they need. There is no doubt that if Grape-growers throughout the country were consulted as to the practicability of keeping the roots in quantity, and in an active condition in both the inside and outside borders for a lengthened period, the majority would say that it could not be done; that if egress were permitted, those growing inside, if even placed there at the time of planting, would make their escape outside, or in a few years cease to make any progress: I am willing to admit that if the actual condition of the roots of the greater portion of Vines that have been so placed in inside and outside borders were conclusive evidence that such opinions are correct, it might be taken as a true verdict. But I maintain that such is not the case; the unerring natural law of self-preservation is as fully illustrated in vegetable as it is in animal life, and when the roots of Vines thus make their way from the inside to the outside borders, they are following Nature's laws in making their escape from the defective treatment they receive inside. There

is no doubt there are many Grape-growers who can afford to make, and who carry out the idea of making, their Vines the whole and only consideration in the houses devoted to their growth; but if we take the country collectively, I submit that the treatment generally given to Vine roots in inside borders is the worst feature in the whole routine of garden practice, and this in nineteen cases out of twenty, through causes over which the cultivators have little or no control.

This state of things has been much aggravated since the summer bedding system has been carried to the extent which it has now reached, for it too generally causes

Lily Bulbs.—"Dunedin's" chief complaint (see p. 293) is that I did not make my sketches to suit his description (see p. 260). This, however, I never attempt to do in any case. I still maintain that my sketch (see p. 268) is correct in all essential particulars. If "Dunedin" be on the golden side of the shield, he should not be too severe upon me if I see only the silvery reverse. As to the statement that I have "made the 'seed-bud' (see p. 268) to sit in the very bosom of a scale double the size of the original," is only part of the truth, seeing that the whole sketch, scale, bud, root-stock, and growing stem, are all enlarged two diameters for the sake of clearness, and if anyone will look carefully at my sketch, they will see that the bud is in no way "attached to that scale," as "Dunedin" states, but is in reality—due allowance being made for perspective—as near the young stem on the right as it is to its attendant scale on the left. Again, "Dunedin" should remember that his specimen was a dried and shrivelled one, and the fact that so good an authority as the "Author of the Notes on Lilies" (see p. 268) was unable either to deny or accept "Dunedin's" statements as facts, shows how vague his own description of his "seed-bud" theory must be, even to experienced Lily growers, and all such with whom I have conversed on the subject have been unable to grasp "Dunedin's" meaning in this matter. This being so, it seems to me highly desirable that—as suggested by the "Author of the Notes on Lilies," and in these pages (see p. 294)—"Dunedin" should settle the point conclusively by exhibiting before the Scientific Committee of the Royal Horticultural Society at South Kensington, or elsewhere, illustrative sections or other preparations of such Lily bulbs as will shew his meaning in a clear and unmistakable manner, and, until that is done, I cannot enter farther into this discussion. F. W. B.

the inside space to be covered as thickly as possible with boxes and pots of bedding plants, both in early, mid-season, and late Vineries. The greater number of gardeners who occupy middle-sized places are obliged to resort to this, and it often happens in the largest establishments that the bedding so outgrows the accommodation essentially devoted to it that the Vineries have to be called into requisition. Then there are shelves of Strawberries in pots, shelves of pots, and boxes of French Beans, rows of pots filled with early Potatoes, and other things of a similar nature, the water from which is daily and hourly oozing through on to the border, rendering its upper surface sour and unsuited to the roots of any plant, and often leading to the impression that it is moist enough all the way through, when frequently it is as dry as a board beneath the immediate surface. The necessity for the inside borders being thus crowded with other plants is no visionary matter, as I can testify, having too often had no other available resource but to subject inside borders to this treatment. All this is bad enough, but there is yet another and a more fatal cause through which Vine roots in inside borders suffer, that is, the unnatural drying process to which they are yearly subjected, wherein the soil, from the surface down to the drainage, is intentionally allowed to become as dry as dust. For Vines that are forced very early all through the summer up to autumn, with a view to prevent their breaking prematurely, the soil is kept in a condition that precludes the possibility of the roots more than barely existing; with midseason crops a similar drying process begins with the berries commencing to colour, and is kept up for a considerable time through the hottest part of summer, when the foliage is green and healthy and the roots taxed to their utmost to supply the loss by evaporation, but which those inside are totally unable to do. In late Vineries, where the Grapes are required to hang long, the drying process commences with the first signs of ripening in August or the beginning of September, and is continued to the end of the year, or as long as there is a bunch hanging; but it is totally unnecessary to submit inside Vine borders to this extreme drying process, as the end in view can be accomplished without it.

Despite all that is said as to the inability to keep the roots of Vines that occupy both inside and outside borders in a plentiful and active condition, I am well acquainted with many instances in different parts of the kingdom, where, in the case of those that have been planted thirty or forty years, or even more, they are now, and always have been in equally good condition both inside and out. I may mention one place in particular with which I have more than an ordinary acquaintance. At Cloughton Hall, in Lancashire, is a range of four moderately large Vineries; there were five, but the Vines have been removed from one, it being converted into a plant-house; two of these were planted by my grandfather some eighty years ago, the others a few years previously; they are wide houses (the inside borders occupying the whole space), and the front walls are arched. So long as I can recollect there has been nothing to indicate the limits of the outside border, but I believe it is of more than the usual dimensions; next the houses is a border filled with bedding plants in summer, then a broad gravel walk; on the opposite side another flower border, and beyond this the vegetable quarters of the kitchen garden. I can speak for the last forty-five years, that there has been no renewal of the outside border, or anything beyond a yearly dressing of manure given to the plants grown upon it, neither has anything been done to the inside border, excepting 12 in. or 15 in. of good soil added to the top. So long as I was connected with the place the roots were always more plentiful inside than out. Recently I received a letter from Mr. Walsh, the present gardener, who describes them as being in just the same condition now, more roots being inside than out. The Vines are a mixed lot, have never been renewed, and have from one to four or five rods each, and I do not suppose that there are any in the kingdom that have all through the long course of their existence up to the present time continued to produce heavier crops of thoroughly well-finished fruit. I saw them last summer, and as one stood at the end of each house the bunches literally appeared to touch each other; the Hamburgs especially were well swelled and as black as jet, many of the

bunches running from 2 lb. to 2½ lb. each, the whole being considerably larger than very old Vines often carry. The causes of their continued fertility and the active condition of the inside roots are not far to seek; there were never many plants tolerated in the houses; next, the inside border has never been subjected to the injurious drying process; and last, but not least, there is a pond of several acres in extent on a higher level some few hundred yards distant, from which comes a continuous supply of water into cisterns in the houses, and which water has been used in the quantities which the roots of healthy Vines require, to the deficiency in which, even during the season of active growth when water is given, is attributable more than to all other causes, the evils under which Vines suffer. So far from it being an impossibility to keep the roots of Vines in healthy working order in inside borders when they have access to outside as well, even more may be done.

In a large establishment last year I saw several houses where the Vines had been planted from thirty to forty years in outside borders alone, and which were as full of active roots as could be desired. Within the last few years inside borders have been made, and the Vines have been induced to root inside, and from my own observation I can testify they are literally teeming with active fibres. These Vines were bearing an abundant crop of very large bunches of fruit, exceedingly well finished, and they carried everything before them at one of the best fruit shows in the kingdom. I could go on multiplying instances of old Vines, whose roots occupying both outside and inside borders are equally in good condition in both, but it is simply unnecessary: in cases of this kind that which is done in a few places may be accomplished in an indefinite number, if similar means be employed. Inside borders alone may do for those who are willing to incur the expense and delay in re-planting from time to time, but the Vine is a strong, free-growing plant that every year makes a great deal of wood and leaf in a very short time, if it have the requisite support; and the simple fault of inside borders alone, however well made in the first instance, and well managed afterwards, is the insufficiency of growing space that they afford the roots. The great advantage with inside borders, as well as out, when the former receive all the necessary attention, is that they render the crop, at whatever season it ripens, in a great measure independent of the weather outside. Were I to have my choice, I should prefer the roots in an outside border exclusively to inside alone, even for early forcing; and for early forcing I would never use fermenting materials on such outside borders, having long since been convinced by experience that, even when used in no greater quantities than to cause the roots to move simultaneously with the shoot development, it is not only useless but injurious. A covering with any non-conducting material early in the autumn, to keep in the accumulated sun-heat of summer, and to ward off rain and frost, is sufficient, as is every year clearly proved by many of the best Grape-growers in the kingdom, especially some of those who grow for market, and whose living is dependent on their success, and who do not often make mistakes.

T. BAINES.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Spice Pippin Apple—This variety is but little known, except in the eastern parts of Essex, and adjoining parishes of Suffolk. It is, however, an excellent Apple, which with care will keep till May. The tree blooms very late, and generally escapes spring frosts. It is a great bearer, and scarcely ever fails to produce a crop, even when nearly all others fail.—B. R. CANT, *St. John's Street Nursery, Colchester.*

Pear Blossom—I cannot remember a season in which Pear blossom has been so fine, regular, and abundant as it is at present on trees of all shapes and in all situations. Although the buds were exceptionally prominent at the beginning of the year, they may now be termed late in opening. The cold and wetness of the ground and the absence of sun-heat have had a most marked effect on Pears as well as on other vegetation.—J. G., *Henham.*

Early and Late Pruning and its Results.—Having read with much interest the articles on early and late pruning of hardy fruit trees by Mr. Fish (see p. 151), and Mr. Baines, (see p. 272), allow me to state that I have a dozen pyramidal Pear trees planted on either side of a gravel walk. I have this year tried the plan of pruning one side in the middle of December, and the other side in the middle of February. The trees are planted one of a sort on each side of the walk in pairs, and there is not the slightest difference in the appearance of the bloom at this time. I also had occasion to remove one of the pyramids to another part of the garden; and that, too, is in exactly the same state as the companion tree, which was not moved. This seems to fully confirm Mr. Baines' view on the subject.—A HEAVY LAND GARDENER, *Cambridgeshire.*

HARDY FLOWERS IN LONDON GARDENS.

DAFFODILS, Squills, Grape Hyacinths, and other early-flowering bulbous plants may still be seen in great beauty in London gardens. *Anemone pulsatilla* and *A. Gloire de Nancy*, too, are now producing an abundance of large blue and purple blossoms; *A. nemorosa bracteata* is just opening its white flowers, and the small sky-blue blossoms of *A. blanda* may still be found on plants that have been blooming nearly all the winter. *Muscari botryoides Szovitzianum* is also in good bloom, its flowers being large and of a rich dark blue colour; the dwarf *Iris pumila*, growing in a bed in Messrs. Rollisson's nursery, is thickly studded with deep violet-coloured blossoms;

Musk-scented Heron's-bill (*Erodium moschatum*).

for edgings or for planting in clumps on rockwork this is one of the best of the small Irises, and one which deserves to be more commonly met with in such positions than it is, as, in addition to its attractiveness when in flower in spring, strong plants of it frequently furnish a second crop of blossoms in the autumn. *Saxifraga crassifolia* still bears abundance of large trusses of rosy-pink flowers, and the early Forget-me-not (*Myosotis dissitiflora*) and *Pulmonaria sibirica* are equally well in bloom; *Ornithogalum splendens*, too, is now flowering freely, and its blossoms being pure white, it is much more effective than the greenish-white *O. nutans*, which may also now be seen everywhere in abundance. *Doronicum austriacum*

Palmate-leaved *Dentaria*
(*D. palmata*).Double-flowered Cuckoo-flower
(*Cardamine pratensis fl.-pl.*).

in some places is now remarkably showy, each plant bearing from twenty to thirty large bright yellow flowers; *Aubrietia purpurea grandiflora* is also at present a mass of bloom; this variety of *Aubrietia* is a desirable plant for edgings or masses; its flowers are larger than those of the common kind and brighter in colour. To the above may be added *Ranunculus amplexicaulis* and *Triteleias*, the latter finely in bloom. Early Tulips are opening fast, and will soon be very attractive. S.

Broad-leaved Groundsel (*Senecio saracenicus*).—This grows wild in moist situations in some parts of the west of England, where it attains a height of from 4 ft. to 5 ft. It is a showy plant, and one which is suitable for planting on the margins of ponds or streams in semi-wild places, where it spreads rapidly, and when associated with the Willow Herb (*Epilobium angustifolium*) a beautiful contrast is the result, the habit of growth and colour of the flowers of each being so distinct and effective.—G. B.

THE LIBRARY.

HARDY PLANTS FOR LITTLE FRONT GARDENS.

THIS little shilling volume consisting of 120 pages, is devoted to cultural and other matters, relating to the growth of hardy flowers in small gardens. It is written in a popular and interesting style, and will doubtless prove of service to artizans and others, who possess little forecourt gardens in or near large towns. The following extract relating to the construction of rockwork will give some idea of the kind of information which is to be found in this handbook.

A tasteful rockery is never obtusive or fantastical, never stands out like a candlestick in the middle of a flat bed. Of all vulgarities in gardening, none exceeds that of an ugly rockery. Anything like an imitation of logan rock or ruin, anything requiring cement to keep the stones in place is in the worst possible taste. Flint stones are very ugly. If used at all, they must be used modestly, and almost entirely be covered by creeping plants. Sandstone, granites, and pebbles contrast admirably with vegetation, and arranged in a natural manner, as if they were at home, are always pleasing. Rockwork should seem to come out of the ground, and not to be made to order and set down where it is to stand. On a small scale, it should never be high, except where it leans against a wall. Rough stones, always excepting flints and clinkers, make a pretty border for central bed or green plot. These stones should not be too high, but allow some lovely dwarf edging plant to rest on them and peep out between. This kind of edging also agrees well with the rockwork, which perhaps fills the corners of the garden, so that the whole of the little domain looks of a piece. But beware of too many white stones not sufficiently covered by green! Of all things, avoid a whitewashy appearance. It is a common fault in seaside gardens, and very painful to the eyes.

One piece of information is, however, withheld which should have had a place in this little work. Quotations are given from Ruskin's "Modern Painters," Darwin's "Climbing Plants," &c. but we fail to find any mention of the cost of, or best ways of obtaining plants, seeds, soils, implements, &c., all matters which we know from experience to be of vital importance to the class for whom the book is professedly written.

AGRICULTURAL TEXT BOOK.*

THE literature of the farm does not as a rule come within our province; the present work, however, is an exception, inasmuch as much of the information which it contains is of especial value to all cultivators of the soil, whether farmers or gardeners. Among the contents of this handy little two-shilling volume are well-written essays on the origin, formation, distribution, physical properties, and chemical composition of soils, together with remarks on drainage, culture or tillage, and the application of manures. The chapters on the latter should be read by every gardener, as should also the remarks on rotation and the relative influence of different crops on the soil in which they are grown. Not the least useful part of this little hand-book are the chemical and statistical tables, cost of labour, manures, &c. In this latter respect we must own that farmers are ahead of gardeners, who nearly always ignore statistics; and we could now refer to many papers on gardening in which the plants or improvements recommended could only be procured, or carried out at a cost of two or three hundred pounds, yet not a word is said about cost, to many the all-important matter. We cordially recommend this little work to the attention of all interested in the "reason why," in reference to soils, manures, drainage, and rotation of crops.—B.

Pearson's Plan of Glazing.—Messrs. Foster & Pearson, Beeston, Notts, say (see p. 264) that glazing with curved glass was introduced about ten years ago by the late Mr. J. R. Pearson. I have, however, two houses here, a Vinery and a Peach-house, erected about fifty years ago, which are glazed on the same plan, and as regards the action of frost, there is no difference between these and houses glazed with glass cut evenly across.—A NORTHERN GARDENER.

EFFECTS OF CHECKED GROWTH ON AURICULAS.

A FEW days ago I had an opportunity of inspecting the fine collection of Auriculas grown by the Rev. F. D. Horner, Kirkby Malzeard, Ripon. His plants are now in a lean-to house on a south aspect, with level stages back and front, and a pathway between them. All the best are on the front stage, and all are in excellent condition. During the prevalence of cold, frosty weather, they have had at night the advantage of artificial heat; there being a brick flue in the house, a little fire is put in when requisite. The Auricula—meaning thereby the fine choice varieties—is practically a greenhouse plant at this season of the year, and is much assisted by warmth when judiciously applied. The weather is generally changeable early in spring, and the evil effects of checked growth are well known to cultivators, and need to be guarded against. The visible symptoms of a check are hardy and defective growth, a gradual blanching of the leaves, and a dulness of the ground colour of the blossoms, with a sere and yellow edge. Such a check in growth affects the roots also; there is a deficiency of action arising from something akin to root paralysis, and as a check from cold is sometimes the source of these evil results, it indicates that the cultivated Auricula is not so hardy as is generally supposed. Hence, therefore, the advantage of greenhouse treatment in February or March, when the energies of the plants are put forth to produce leaves and blossoms. When in a dormant state, the Auricula will withstand the effects of frost with comparative immunity; the autumnal growth of leaves has become hardy and of a thick substance; but it is different with the young growth and the rising flower-stem; they appear to partake of a tenderness that demands protection. The cold north-east winds of spring need to be guarded against, or they strike the plants with a chill, and the buds remain in suspense and do not expand. The roots, owing partly to their being underground, are not stimulated into action so soon as the foliage is, consequently the latter, by its attempts at growth without due support from the roots, exhausts itself and injures the health of the plants, and any check given to the foliage during growth is communicated immediately to the roots. I confess that I was a little surprised at the warm temperature which the Rev. Mr. Horner was giving his Auriculas during the cold weather of the week commencing March 19, but the condition of his plants fully justified the treatment. The late Rev. George Jeans once wrote:—"The Auricula in its high state of artificial cultivation, and removed from its protecting snows and grown in pots, whereby its roots are brought to the very focus of opposite external influences, is little more than a half-hardy plant. Wherever anything looks amiss above the soil, except it be rot or canker, I believe that a sluggish and unhealthy root action, or no action at all, will be found below, and one of the surest means of inducing that state is the permitting of the foliage to receive a check from frost or from cold, and drying winds during growth." Such cautions as those contained in the foregoing remarks are all the more necessary because there is abundant evidence that the ranks of Auricula cultivators are being recruited by those desirous of attempting the growth of this fascinating flower. D.

Nicotiana macrophylla gigantea as a Winter-blooming Plant.—Last year I was very successful in blooming this plant in the greenhouse, and really handsome it was. The house in which it bloomed is kept at a minimum temperature of 40°, rising with sun-heat, but rarely being above 50° in the winter. The seeds of this Tobacco were sown in heat in March in order to supply plants for outdoor decoration, and when large enough, they were potted off into 3-in. pots. About the end of April they were shifted into 10-in. pots and placed in a cold frame; in June they were set out-of-doors, where they threw up bloom-spikes about the end of September. Some time in October they were taken into the house, and in November the blooms began to expand. When the first spike had nearly done blooming, it was removed, and laterals formed, which flowered freely, in some cases producing heads of bloom 1 ft. and 1½ ft. across. The pink blooms of this Tobacco are very attractive, and the foliage, being of a pleasing shade of green, renders the plant effective during the dull season of the year, and to those having small houses only, very useful. The soil which I used consisted of about equal parts of leaf-soil and fibrous loam, a little sand being added to keep it open; the drainage, too, was ample.—W. J. MAY.

Preventing Snails from Eating Young Melon and Cucumber Plants.—When Melons and Cucumbers are planted out in a young, tender state in spare beds, they are very liable to be eaten and rendered useless by snails. I have seen many healthy young plants destroyed in this way in one night. In planting I now always lay a ring of powdered lime a few inches from the neck of each plant, and this forms an effectual barrier to the progress of the snails.—A NORTHERN GARDENER.

PLATE LXX.

EDRAIANTHUS AND ITS CONGENERS.

(WITH A COLOURED FIGURE OF E. PUMILIO).

Drawn by H. NOEL HUMPHREYS.

EDRAIANTHUS Pumilio is so much like a true Campanula that it is not easy to discover any distinctive characters; indeed, by turns it has borne the names Campanula, Wahlenbergia, and Edraianthus Pumilio. From the first genus as now usually limited, it is excluded on account of the seed-vessel splitting open on the top between the calyx lobes, instead of in lateral clefts. In Bentham and Hooker's "Genera Plantarum" Edraianthus is made a section of the large chiefly (South African) genus Wahlenbergia. The genus Wahlenbergia, even in this extended sense is almost unknown in gardens, and consists mainly of comparatively small-flowered, not particularly ornamental plants. The section Edraianthus comprises about half-a-dozen species, inhabiting the mountains of South-eastern Europe and Asia Minor. They all have the tufted habit and narrow leaves of E. Pumilio, but this is the smallest of the series. It is a native of the mountains of Dalmatia, growing in the fissures of rocks. In habit it closely resembles *Silene acaulis*, the wild specimens being only 2 in. to 3 in. high, including the flowers. The shining foliage is hairy and of a silvery grey hue. The accompanying figure will give an idea of the beauty of this species when in full bloom. Concerning its cultivation, it should be borne in mind that it is in the true sense of the word a rock plant, and requires an open situation such as that which it occupies in Messrs. Backhouse's nursery at York, from a specimen growing in which the annexed plate was prepared.

Judging from dried specimens alone the other species of this section must be equally attractive. *E. tenuifolius* and *graminifolius*, natives of Greece, Bosnia, &c., grow from 3 in. to 6 in. or more high, and have narrow, Grass-like leaves, chiefly radical, and flowers nearly double the size of those of *E. Pumilio*. *E. serpyllifolius* is scarcely larger than the present species, and has, as the name indicates, Thyme-like foliage; it is also at home in Dalmatia. *E. Kitaibeli*, a native of Bosnia, about 6 in. high, and having proportionately larger flowers, differs from all the others in having appendages in the sinuses of the calyx-lobes, like some of the true Campanulas.

In conclusion, a few words respecting one or two other species of Wahlenbergia of a totally different habit. First of all, the incomparably beautiful little *W. hederacea*, or Ivy-leaved Bellflower, a native of peaty bogs and humid spots, chiefly in the south and west of England, northward to York and the Clyde, in Scotland. Beyond Britain it has a wide range, chiefly in the coast regions, from Denmark and Ireland to Spain and Dalmatia. Without being a showy plant, it is certainly one of the gems of our indigenous vegetation, and should be included in every garden where there are facilities for cultivating bog plants—not that it is absolutely a bog plant, but it is difficult otherwise to give it suitable conditions. Although a native plant, it is not so common as to be familiar to those who do not explore our woods and wilds, to enjoy the scanty remnants of Nature left in this country; and therefore a short description of specimens lying before me collected in St. Leonards Forest, Sussex, may be acceptable. It is a perennial with trailing, slender, thread-like stems, branching repeatedly, and attaining 1 ft. or more in length when luxuriant, and delicate, membranous, angularly-lobed, Ivy-like leaves about ½ in. in diameter, and borne upon slender stalks, the lower of which are nearly 1 in. long, getting gradually shorter towards the tips of the branches. The pale blue flowers are less than ½ in. long, and are borne on exceedingly slender stalks about 1 in. long. At first they are pendent, gradually becoming erect, and after the corolla has withered and the seed-vessel enlarged and become too heavy for the slender stalk to support erect, it droops. Another species of this genus, *W. lobelioides*, was introduced from Madeira into English gardens in 1777, but it is now rarely grown, being more curious than beautiful. It is an erect, slender annual from 6 in. to 2 ft. high, according to the soil, with small, terminal, pink or white flowers less than ¼ in. in diameter, and remarkable in having usually only three instead of five

SILVERY HAIRBELL (EDRAIANTHUS PUMILIO-D. C.)

lobes to the corolla. On account of their singularity, the shrubby species found in the islands of St. Helena and Juan Fernandez deserve notice.

W. B. HEMSLEY.

THE SCOTCH GOLDEN-EDGED HOLLY.

THIS is a new form of Holly, with a singularly vivid and striking variegation. It has an irregular golden margin bordering a centre of rich shining green, and the effect is singularly bright and pretty.

This Holly is in the possession of the Lawson Seed Company, and will be sent out by them. It was originally raised in the Comeley Bank Nursery, Edinburgh.

Gold-laced Polyanthuses.—I am much obliged by Mr. Cocks' communication (see p. 303), but I am afraid that he has scarcely comprehended my desire. It is to obtain a collection of the fine old-named Gold-laced Polyanthuses that were so popular twenty-five and thirty years ago. I have raised seedlings for years past, and have a few that are of great promise, but a real good one, perfect in all parts, is one in five thousand. Since I wrote I have, however, been enabled to enrich my collection by the addition of George the Fourth, William the Fourth, Formosa, Telegraph, Exile, and one or two others. On strong plants Lancer is now very fine indeed, and when one compares a bloom of it with the best productions of the seedling bed, they realize what is wanted in the seedlings. I am yet in want of Lord Lincoln, King Fisher, Alexander, Beauty of England, Princess Royal, King, Highland Mary, Duke of Northumberland, and Royal Sovereign, and if any one can assist me to the possession of plants of these varieties, I shall be very grateful.—A. D.

Bedding Violas.—The spring, in spite of a comparatively mild winter, has not induced the Pansy tribe to bloom early, a circumstance probably owing to the excessive rainfall which we have had rendering the soil moist and cold. In the south the chief value of bedding Violas depends upon their blooming early, and the earliest among the early is that beautiful Viola called White Swan, which is a valuable spring bedding kind. Amongst the blue section the new Royal Blue, a seedling from Blue Bell, occupies the first place, for it is not only the earliest, but its flowers are literally the bluest of any Viola in cultivation. It has a dense, close habit, and blooms most profusely. In Yellow Boy, a greatly improved variety of *V. lutea grandiflora*, we have incomparably the earliest of the yellow kinds, and it is a first-rate spring bedder. The dwarf lilacina, which is mauve-coloured, flowers abundantly, whilst the pretty primrose-coloured Corisande is the earliest of that particular hue.—A.

The Best Lilac for Forcing.—At a recent meeting of the Central Horticultural Society of France, M. Duchartre adverted to his experiments made some years ago on the Foschi Lilac. The learned professor then showed—and his results have been abundantly confirmed since—that by forcing a Lilac in a well-lit forcing-house at an average temperature of 59° Fahr., perfectly white flowers were produced. In one of his experiments one branch of a Lilac was allowed to escape into the open air through a hole in the glass, while the rest of the shrub was within the forcing-house. Under these conditions the forced flowers were white, as above, but those which were on the branch exposed to the open air expanded a fortnight later, and were of the ordinary lilac colour.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Glass Structures.—Amateurs, whose glass accommodation is limited, are often tempted to grow a greater variety of plants than can receive proper treatment in the space allotted to them; there is also frequently a disposition to form collections of a certain species of plant. In neither case is there so much pleasure derivable as in a selection sufficiently restricted to admit of all the plants having sufficient room to attain their full development and exhibit their true character, besides which the general health and appearance of the plants when overcrowded can never possibly be at their best while their blooming capabilities are considerably diminished. The most desirable course is to make a selection of those subjects that are naturally free growers, handsome in appearance, last a considerable time in flower, and will answer well for cutting. The above remarks collectively apply even more to stove subjects than to such as succeed under cooler treatment, as the former, from their more rapid growth and the usually limited space for their cultivation, are more likely to get overcrowded. It is now time to commence propagating the various plants usually grown for winter flowering, and in the selection of these it is well for amateurs to bear in mind the above hints, and to confine themselves to the most useful varieties. Amongst the most indispensable of winter-bloomers, either as decorative plants in the stove, or for their remaining fresh for a long time in a cut state, are Poinsettias; the new double variety, in all probability, will ultimately be grown to the exclusion of the old single form, and those who possess a plant of it should lose no time in increasing it. Last season's growth should not be shortened; simply place the plants in the warmest available situation, keeping the soil slightly moist, which will cause the top eyes to break; when these are 6 in. long take each off with a heel of the old wood, and insert them singly in sandy soil in small pots, and cover with a bell-glass. If cuttings of Poinsettia be not made with a heel of the old wood attached, as above recommended, but are simply severed at a joint, as is customary with cuttings of most plants, many of them will rot, on account of the succulent nature of the shoots. When the leading eyes of last summer's growth have thus made shoots and been taken off, the lower ones will break and can be similarly treated until all have pushed down to the base, which most probably they will not accomplish before midsummer, the last struck plants coming successively into flower late in the winter. In propagating the old varieties of Poinsettia, both red and white, adopt the same course, but where the stock is plentiful they will most likely furnish a sufficient number of shoots at once; ability to flower in succession in their case can be secured by subsequent treatment. The equally indispensable and more elegant *Euphorbia jacquiniæflora* must be propagated in the same way by cuttings with a heel or a bit of the old wood attached, otherwise the greater portion of them will fail to root. They may be either struck singly in small pots or inserted eight or ten round the sides of 6-in. pots and potted off singly when struck. The red-flowered *Sericographis Ghiesbreghtii* is one of the best winter plants we possess, striking freely from cuttings of the young wood treated in the ordinary way; like the two preceding subjects, it does not require a great amount of space for growth, 8-in. or 9-in. pots being large enough for it. The flowers of the beautiful rose-coloured *Plumbago rosea* have a charming effect in the winter when remaining on the plant, but as they do not keep fresh so long when cut as some subjects, it is not advisable, where space is limited, to grow many of them. Cuttings made from the young wood, put in now, grown on through the summer near the glass, and stopped at times to make them branch out, will become fine blooming specimens by the autumn. Blue flowers in the winter are scarce, and there are few of this colour from which to make a selection. *Eranthemum pulchellum* is very useful and one of the best; it is easily grown, and blooms profusely from the points of every shoot, however small; plants that have flowered during the winter will at the present time have a number of young shoots on them 3 in. or 4 in. in length: treat similarly to the last-named. *Aphelandra cristata* is another plant that remains a considerable time in flower; it is very handsome, and will bloom in either a large or small state; it forms stout, short, erect growth, the plant requiring little or no support; it will have made young shoots from just below where the heads of flower were produced in autumn, and these will now be in condition for making into cuttings; they thrive best singly in small pots. This *Aphelandra* will last for many years, and can be kept within moderate limits, as it will bear cutting back each season to within a joint or two of where it has been headed down the year previous; plants of it will flower freely in the autumn, if those that have bloomed be so treated now, kept in the stove until they have broken into fresh growth, then turned out of the pots, two-thirds of the old soil removed, replacing them in the same or larger ones, according to the required size of the plants, and kept on in heat through the

summer. The comparatively new *A. Roezli* is a pretty, free-flowering plant, blooming in a 4-in. or 5-in. pot; when not more than from 4 in. to 6 in. high, through the winter and spring, it is very effective when grown three or four together in 6-in. pots. Now is the time to strike cuttings, keeping them in the stove through the summer; they require no further attention except a sufficiency of light, air, and water; they succeed best in turfy loam and a little sand. The above plants are deserving of a place in the most select company, and are in every way suitable for amateurs, as their flowers contrast well with any others. For autumn flowering, *Salvia gessneriflora* and *S. fulgens* are two most useful plants easily grown; cuttings put in now will root in a fortnight, when they can be moved singly into 3-in. pots, the points pinched out two or three times during the summer, giving root-room as they require it. There is one advantage attending all the foregoing subjects, viz., that where space is limited they will bloom well the following autumn and winter from spring-struck cuttings, consequently, after flowering all can be discarded, except just a sufficient number from which to obtain cuttings.

Solanums.—The berry-bearing *Solanum capsicastrum* and *S. pseudo-capsicum* have a very much better appearance when grown in the open ground and transferred to pots in the autumn than when grown all through the summer under glass, as outside they assume a much closer habit, and the foliage becomes more dense and better in colour than it can be had in pots, even with the best attention. Under pot culture if ever the plants be allowed to suffer from want of water the leaves always turn to a yellow, sickly colour; besides there is invariably a difficulty in keeping down red spider; under open ground cultivation it is essential to plant them out early if their berries be required in a ripe state early in the autumn. *Solanums* are much hardier than they are generally supposed to be; 10° or 12° of frost will not seriously injure them. Plants that have been used through the winter should be cut back, reducing them to one-third their size, turned out of the pots (removing most of the soil without breaking the roots more than can be avoided), and at once planted 18 in. apart in a sheltered situation fully exposed to the sun. If the soil be not of a loose, open nature, it must be made so by the addition of sand or vegetable mould of some kind, for if the material in which they are grown be of an adhesive character, when they are taken up for potting the roots will get broken to an extent that will seriously injure them. Young plants of these *Solanums* struck from cuttings or raised from seeds some weeks back may be planted out in a similar manner, but previously they must be sufficiently hardened off.

Bedding plants.—See that the stock of each kind of bedding plant required is sufficient to cover possible losses. Such as *Heliotropes*, *Ageratum*, *Lobelia*, and *Verbenas*, that root and grow quickly, may yet be struck. The tops of the first-struck plants will make excellent cuttings. *Pelargoniums* should now be moved out of the greenhouse into cold frames, giving those that are of sufficient size plenty of air from morning till night to harden them off; such as are small should be encouraged to make growth by keeping them closer, especially by shutting down the lights early in the afternoons. The tri-coloured bedding varieties will be better for being kept moderately warm until the end of the month. *Humea elegans*, *Wigandia*, *Chamaepeuce*, and *Cannas*, should not be kept in too small pots until planting-out time, or they become weakened, the bottom leaves suffering, which spoils their effect for the summer. *Alternantheras*, *Iresines*, *Coleus*, and *Amarantus*, must be kept for some time yet in a warm growing temperature. Pot off *Dahlia*s as they are struck, and put in more cuttings; these later growths, which are somewhat weaker, generally strike more freely than the strong, sappy shoots first produced.

Kitchen Garden.—Make further sowings of Peas and Broad Beans as soon as those last put in are fairly aboveground. From the cold, wet condition of the ground this spring many of the early-sown vegetables make such slow progress that it is necessary to defer successive sowings a little longer than usual, otherwise the crops will be ready for use too near together. Sow a little Turnip seed, as also the main crop of Carrots; these should, if possible, occupy ground that is of a light, open nature, and, like all deeply-rooted plants, should have it dug to a good depth, and it ought to be tolerably rich land that has been heavily manured last year and had grown Caniflowers, Lettuce, or Celery, it being better not to apply fresh manure directly to the Carrot crop, as it tends to cause their cankering: sow thinly in rows 12 in. or 15 in. apart. Where Beet is held in estimation, and is required as early as obtainable, a little may now be sown, but it is better to defer putting in the principal crop until somewhat later, for should a dry summer ensue, it will have a disposition to run to seed. Where Seakale is grown from seeds sow at once in rich, open soil; it will succeed better in such

than where it is heavy and adhesive; if the ground be well manured and the plants kept free from weeds through the summer, they will make good crops for forcing next winter. Pat the seeds in from four to six together in patches 15 in. apart in the rows, having the rows a similar distance asunder. When the plants are up thin out to one in each place.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

April 23.—Potting off *Cyclamens*, *Lantanas*, *Globe Amaranthus*, the last of the *Dahlia*s, and stove cuttings; also potting seedling *Centaureas*, *Vegetable Marrows*, *Cucumbers*, and *Melons*. Sowing *White Cape* and *Miller's Late Broccoli*, and *Paxton's French Beans*. Planting *Violets* and *Lettuces* from frames, and pricking off herbaceous *Calceolarias*, *Ice-plants*, and *Sweet Basil*. Putting in cuttings of *Alternantheras*; also another batch of *Pinks*. Preparing frame for pricking out *Celery*. Earthing-up *Melons*, and top-dressing *Peach trees* in houses. Thinning *Grapes*. Syringing *Apple trees* in orchard with alum-water to kill blight. Putting strings over *Peas* to keep off birds. Taking lights off bedding plants on all favorable opportunities. Tying down *Vine shoots*, and keeping *Muscats* in flower at 70° at night and not giving air by day until 95°.

April 24.—Putting *Lilacs*, large *Balsams*, *Coleus*, and *Epacris*, into larger pots. Sowing *Indian Pinks* and *Mignonette* in the flower borders; also *Dianthus Heddewegi*, *Centaurea Cyanus*, and *Aubrietia purpurea* and *græca*. Planting spring-sown *Caniflowers* between *Asparagus beds*, and *Lettuces* on *Celery ridges*. Making a new bed of *Keen's Seedling Strawberries* with plants that had been forced. Moving all *Dahlia*s out of heat. Emptying and re-filling vases on terraces with fresh soil. Stopping fruit tree shoots in orchard-house. Syringing *Peach trees* on walls out-of-doors with a mixture of *Tobacco-water* in order to keep down green and black fly. Digging up and removing *Winter Greens* as fast as they become useless.

April 25.—Potting off *Verbenas* in 3-in. pots, and placing them in warm frames. Shifting *Melianthus* into larger pots, also *Gnaphalium* and *Capsicum*. Sowing another batch of *Primulas* and *Balsams*; also *Brussels Sprouts*, *Curled Greens*, *Cottagers' Kale*, *Buda Kale*, *Walcheren*, *Backhouse's White*, and *Snow's Winter White Broccoli*. Planting *Asparagus* on newly-prepared beds; also more *Caniflowers*, and a border of *Lettuces*. Moving pot *Figs* from *Orchard-house*, and plunging them in leaf-mould in pits. Whitened the ends of lean-to *Orchid-houses* on which the sun shone too fiercely. Dipping *Capsicum*s and *Chrysanthemums* infested with green fly in *Tobacco-water*.

April 26.—Potting *Mrs. Pollock Pelargoniums* and *Perilla*. Shifting standard *Heliotropes* and *Ridge Cucumbers* into larger pots. Planting out *Neapolitan Violets* and hardy *Azaleas*. Hoeing among spring flowers, thinning *Turnips*, and examining *Rose trees* for maggot. Watering *Potatoes* in frames, and afterwards earthing them up. Preparing manure for *Cucumbers* and *Melons*, and top-dressing *Cucumber plants* growing in large pots and tubs with rich loam. Keeping *Alicante Grapes* that are in flower at 70° at night.

April 27.—Potting *Czar Violets* for blooming next spring. Shifting *Celosias* into 6-in. pots, and potting off *Cockscombs* and other young *Humeas*. Sowing *Fulmer's French Beans*, more *Radishes*, and *Mustard and Cress* on borders; also sowing main crop of *Scorzonera* and *Salsafy*. Hoeing among growing crops. Earthing up *Potatoes* on early borders. Watering *Carrots* in frames, and syringing *Peach trees* out-of-doors with *Tobacco-water* and soft soap. Shifting *Gnaphalium*s from houses into cold pits, and giving a little *Stauden's Manure* to *Azaleas*, *Camellias*, *Heaths*, and *Epacris*. Making up hotbed for *Pink cuttings*, and staking and tying up the flower-spikes of herbaceous *Calceolarias*.

April 28.—Potting *Anno Boleyn Pinks* in a mixture of cow manure and loam. Shifting young *Fuchsias* into 8-in. pots for conservatory decoration, and potting off *Mesembryanthemum*s and spring-struck *Heliotropes*; also shaking out and re-potting standard *Verbenas*. Sowing *Paris White*, *Green Cos*, and *Neapolitan Cabbage Lettuces*; also *Marjoram* and *Veitch's Globe Turnip*. Thinning fruit in *Peach-house*, leaving one to each shoot. Getting frames ready for annuals. Putting saucers under *Strawberry plants* that have set their fruit. Keeping *East Indian Orchids* at 70°, *Phalænopsis* at 70°, *Dendrobium*s at 70°, *Cattleyas* at 65°, and *Odontoglossum*s at 55° at night.

Notes on Hardy Flowers.

ANTIRRHINUMS.—Plants obtained from seed sown in August last should now be planted out to bloom early in summer; and those got from seed sown now in a gentle heat would succeed them by flowering in September. Thirty years ago, when the late Mr. J. Riley, of Huddersfield, took Antirrhinums in hand, it is recorded that individual plants of them grew to an enormous size; one specimen being, it is said, 7 ft. high by nearly 4½ ft. through. This is much too large for ordinary gardens, but it shows what can be done with plants under good cultivation. The Tom Thumb varieties are very pretty indeed, forming neat little tufts when in bloom, but they should be raised from seed each year, as the two-year-old plants make taller growth.

ANEMONES.—These require an open and not too wet a position; they do well in a deep, rich loamy soil on the gravel. Beginners would do well to commence with some of the pretty Dutch varieties, double and single, which are well worth attention and not too high in price.

AUBRIETIAS.—These early, spring-blooming, hardy plants are now charmingly effective when grown in masses. Well-established patches will bloom well in almost any soil, and they bear the exposure of winter and heat of summer with but little injury. The best form met with is *A. Eyresi*, a kind with large bluish-purple flowers. *Arabis alba* and *Alyssum saxatile compactum*, used in conjunction with the Aubrietias in spring, make an effective display.

CHEIRANTHUS.—*C. Marshalli* and *C. alpinus*, the former with orange, the latter with pale yellow flowers, are now coming into bloom. Being dwarf and compact they supply good masses of colour in April and May. The former is a hybrid between *C. alpinus* and *Erysimum Peroffskianum*, and seedlings raised from it will show a mixed character, some quite reverting to the annual form. Some pretty hybrids have been raised by the Rev. H. Harpur Crewe, some of which may be seen at Castle Ashby, and I have recently seen two or three thoroughly good seedlings obtained from *C. Marshalli* and the pretty Belvoir Castle Dwarf Yellow Wallflower. Among Wallflowers the two best are the Belvoir Dwarf Yellow and the rich dark Covent Garden variety; Young's Blood Red and Golden Tom Thumb are both also very showy. Wallflowers are frequently sown too late; instead of the seed being in the ground in April, it is not sown till June and July, much too late to get good plants by autumn. The old double dark and double German Wallflowers will soon be in bloom in cottage gardens, and the double German varieties are also well worth culture. Some of these were to be seen in pots at the recent Spring Exhibition of the Newcastle Horticultural Society, with large, full, Balsam-like flowers. Some of the single German varieties are very pretty, such as these with purple and blue shades.

IMIAS AND SPARAXIS.—These beautiful Cape bulbs will now be coming into bloom, where grown in pots in a moderately warm or cold greenhouse. I have seen them grown twenty in a pot well-drained, the bulbs being potted in a mixture of sandy-peat, leaf-mould, and a little loam. If potted in October, the soil should be slightly moist, and the pots placed in a cold frame, or house, and kept there till the foliage is 4 in. or 5 in. in height; they should then be taken into the greenhouse to bloom. *Cyclobothras* and *Babianas*, treated in the same way, are also very pretty.

HOLLYHOCKS.—Choice-named varieties, that have been wintered in pots, should be planted out at the end of this month, or early in May. Some cultivators recommend planting in well-manured trenches, so that the plants can be freely watered in dry weather, as the best preservative against the Hollyhock fungus. Hollyhocks that were planted out last autumn are now commencing to make strong growth; the soil should be stirred about them, and when dry weather sets in a mulching of short manure about the roots will be of great benefit to them. The stronger and more freely the plants grow the greater is their power to resist disease.

PANSIES AND VIOLAS.—Seedlings, raised in autumn and planted out in February, are now coming into flower, and they will now bloom throughout a great portion of the summer; they will be greatly benefited by a good soaking of water in June, when the weather is dry, and then a top-dressing of soil, such as the siftings from a potting bench. Some seed should also be sown now to yield a supply of plants to flower late in summer and autumn. A new variety, named Royal Blue, is very effective in the open air; its habit of growth is dwarf, dense, and spreading, and there is a great profusion of bloom. It is one of the earliest of the blue varieties, and will quite supersede the old Clivedon Blue in the spring flower garden.

THE INDOOR GARDEN.

AZALEA INDICA AND ITS CULTURE.*

For some years past cultivators have devoted much time and attention to the cross-breeding of Azaleas with the view of improving the quality and colour of the flowers of the different varieties, and it is very gratifying to know that their labours have not been in vain, as all the best sorts now in cultivation are cross-breeds. The numerous varieties of this genus are invaluable for furnishing the stages of conservatories at a season when good flowers are scarce. If a number of the early and late flowering kinds be at command and properly managed, they may be had in flower from Christmas to May; but to accomplish this, proper accommodation is required for the necessary forcing and retarding of the early and late varieties. They are also of equal value for exhibition purposes, for floral displays on dinner-tables, in drawing-rooms, saloons, entrance halls, and they are indispensable as cut flowers for bouquets. In fact, I may say that their merits are sufficiently known to make them popular plants with every one who has glass structures in which to grow them.

Modes of Propagation.

The propagation of the plants is effected by seeds for new kinds; by cuttings; and by grafting, for multiplying individual species or varieties. Seeds should be saved from the best sorts only, the flowers of which have been fertilized with the pollen of another variety with the view of improving the colour and substance of the parent, or with the hope of securing a young progeny of stronger constitution. The hybridiser always has some object in view, and is guided by his own ideas in endeavouring to secure such object. The flowers having been fertilized, they should then be protected with a piece of thin gauze to prevent further impregnation by insects, at the same time placing the plants where they will enjoy plenty of light and air and where they can be kept dry. After the flowers have faded the thin gauze may be removed, as there will then be no necessity for it to remain over the flowers. The seed should be gathered as it ripens, and be sown in pans in rough peat early in January, placing the pans in a close warm house and covering with panes of glass, never allowing the soil to become dry, or the seeds may perish when they are germinating. As soon as the seedlings make their appearance remove the panes of glass and keep the pans in a humid gentle warmth, with as much light as possible, and as soon as the seedlings are large enough to handle, pot them into thumb-pots in a compost of sandy peat, placing them in a similar situation to that recommended for the seed-pans until the plants are established in the pots, when they may be treated as will be recommended for established plants. Shading from the sun will be necessary for the plants until they are strong enough to endure it. In propagating from cuttings these should be taken from the shoots of the current year, selecting those that are moderately strong. When the wood becomes a little hard, or what is known as being half-ripe, the points should be taken off about 2½ in. long; cut below the lowest joint, removing one or two of the lowest leaves from the lower part of the cutting, and then insert them in small pots filled with very sandy peat, say six, ten, or twelve cuttings in each pot according to their size; plunge them in a bottom-heat of about 80°, with a top-heat of 70°, where, if carefully attended to, nearly all the cuttings will grow, the principal points to attend to being shade and moisture. As soon as the cuttings have made roots they should be gradually exposed to more light and air, be potted off, and kept in a close atmosphere with a little shade until they are established, when they may be treated as other established plants. Although the propagation by cuttings is a speedy way of raising a stock of any desirable variety, still it is not a system that I would recommend, because plants from cuttings never grow so compactly as those obtained by grafting. Plants from cuttings are also very liable to produce a quantity of gross shoots or suckers from their base, which is detrimental to the plants, and although these are frequently removed, the plants will have a tendency to throw up more. I

* Road by Mr. OLLERHEAD before the Members of the Wimbledon Gardeners' Society.

have also noticed that some varieties struck from cuttings are very liable to die off even after they have attained a great size without any apparent cause—a circumstance which I must say is very grievous to the cultivator. If you wish to propagate Indian Azaleas by grafting, you must first obtain a supply of stocks, which might be raised from seed saved from the strong-growing varieties and treated in the way as previously recommended, selecting the strongest-growing seedling plants, and when these have attained sufficient strength, work on them the varieties desired to propagate; or stocks may be raised from cuttings selected from such vigorous-growing kinds as *A. phœnicca alba*, or Fielder's White, and when these have attained sufficient strength, they may be operated on in the usual way. The best mode of grafting is that known as side-grafting. The scions should be taken from the parent plant about 1½ in. long, then with a sharp knife make a long slanting cut to the base of the scion. A similar slice must be taken out of the side of the stock so that the outer edges of both stock and scion will meet together, which is a matter of great importance to insure success; they should then be neatly bound together with a piece of worsted, and be placed in a close frame in a propagating house or similar situation, and be carefully attended to with a proper supply of moisture. The best time to graft is during the spring. After the scions have united to the stock and they have made a little growth, the ligatures should be slackened, and the plants exposed to a little more light and air; and when they are considered to have made a perfect union, the bandages may be entirely removed, the head of the stock be cut off close to the scion, and the plants exposed to the temperature of an intermediate-house until they have completed their season's growth, when they may be treated in the same way as established plants. Although I have given an account of the propagation of these plants, I do not mean to say that a cultivator would be studying economy to propagate his own plants, as he would have to wait a long time before he would have the pleasure of seeing flowers, and unless he paid unremitting attention to them, in all probability he would lose the majority of his young plants. In nurseries where Azaleas are propagated by thousands, men are employed for the special purpose of attending to their wants, and this being their only study they succeed in turning out ninety-nine plants, and very often a hundred, out of every hundred grafts. This places nurserymen in a position to offer good plants well set with flower-buds at a very reasonable rate. Such being the case, I fail to see where true economy lies in any cultivator trying to propagate his own Azaleas.

Culture.

We now come to the general cultivation, and will commence with such plants as are usually met with in the trade—I mean those well studded with flower-buds and grown in 4-in. and 6-in. pots. Should it be desirable to obtain specimens as quickly as possible, I would advise the cultivator to pick out all the bloom-buds and place the plants in a little heat early in the year, so as to excite them into growth. When growth has commenced they should have a liberal shift into pots a size or two larger, using the following compost:—To five barrowloads of strong fibrous peat (not adhesive, nor yet that light fibry material we so repeatedly see used) add one barrowload of light turfy loam with a liberal mixture of sand. This should be all pulled to pieces, not chopped, and the fine drossy material rejected, the sand to be well mixed through it, and if damp it should be put into a dry open shed, and turned several times before using. Avoid making it dust-dry, otherwise there would be some difficulty in inducing it to take water after the plants have been potted. The best way to test the soil is to thrust the hand into the heap and bring out a handful from near the centre, squeeze this up in the hand and then drop it on the floor; if it fall freely to pieces, the compost may be used; but, on the other hand, should it adhere together, the heap should be turned once or twice before using. After the plants have been potted they should be placed in gentle heat, kept well syringed, and shaded from the sun, giving little or no air until they have hold of the new compost, after which time the temperature may be increased to 60° at night, with a rise to 75° in the day, or 80° by sun-heat; keep the passages, walls, and stages well deluged with water, but take care not to give

too much water to the roots. When the plants are established they will be benefited by a weak application of Standen's Manure or cow-mannre water. I have repeatedly watered Azaleas with water strongly impregnated with cow-manure, but I always take the precaution of applying it to well-established plants. Under this treatment the plants will make rapid growth, and will set their flower-buds early in the season, but the sooner these can be removed the better; push the plants on into a second growth, which is desirable to have accomplished as early as possible in order to give the plants a good rest preparatory to making two growths the following year; but also in this case the flower-buds should be removed as quickly as possible, and not be allowed to remain to waste the energies of the plants. By repeating this treatment for a few years, it is astonishing how quickly specimens may be prepared for exhibition. But should the cultivator not wish to grow them for exhibition, but merely require them for home decoration, the plants may be grown in a much cooler temperature. They will thrive well, and set their buds well in a temperature of from 60° to 65°, or even lower. Some cultivators place them out-of-doors in the month of May or June to finish their growth and set their buds; but this, in my opinion, is a practice that cannot be too strongly condemned. The plants are subjected to heavy rains, which are anything but beneficial, but rather otherwise; and although an attendant may be there to turn them on their sides in the daytime, it is not always that they are on their sides during heavy rains in the night. Some cultivators place them in their Vineries in order to make their growth, and doubtless such situations are favourable for the development of the plants, but the fact that they introduce thrips into such structures is quite sufficient to induce the cultivator to keep them out. In reference to preparing plants for forcing, some early-flowering varieties should be selected and pushed into growth as early as possible, so as to set their buds early in the season, and these should be well advanced before the plants are allowed to rest, as on the state of the buds entirely depends the time required for forcing them into bloom. If they be properly managed, the plants should flower in eight weeks after being introduced into heat. If blooms be not required before April, a temperature of 40° will suffice. In my last situation I found a number of Azaleas in a very bad state, with scarcely a flower-bud on them. Immediately they commenced growth I gave them a partial drying, and had some soil (as previously described) in readiness, and turned the plants all out of their pots, beating the soil out of the roots with the flat side of a spade; in fact, I shook them out just as clean as if they were *Pelargonium*s, thinned out all weak wood, and after potting them into smaller pots I devoted a house to them and treated them in the way described for exhibition plants, except that I left the bloom-buds on the second growth, after which I was well rewarded with an abundant display of flowers the following season. Azaleas should never be allowed to flag from want of water, as this would be sure to end in the loss of foliage. When watering them always fill up the pots sufficiently to cause the water to moisten the whole ball of soil. Always keep them well supplied with moisture during the growing season until the buds are set, then cease syringing overhead, but let the passages and walls be moist, except in frosty and dull weather. Never water the plants until they require it, and always keep them free from insects. Never adopt that detestable system of training by twisting and crossing the shoots to bring the plants into a stiff unsightly shape; but carefully tie out the branches and encourage the shoots to assume a natural appearance. In potting always pot firmly.

Insects.

Azaleas are liable to the attacks of brown and white scale. These may be destroyed by turning the plants on their sides and giving them a thorough syringing with water heated to 140°, turning the plant round as the operation is going on, so as to make sure that every portion has its share of hot water; but be careful to keep it from the roots. Brush the leaves and stems in half an hour after the application, and if not effectual, repeat the dose; or use Gishurst compound, 8 oz. to a gallon of water heated to 140°, and apply the solution in the same way; or soft soap in the same proportions. Any of the above

remedies will be effectual; but they must be applied when the wood is ripe. They are also frequently infested with thrips, the best remedy for which is to fumigate strongly with Tobacco every other night for a week or so; or give the plants a thorough syringing with Gishurst compound, 4 oz. to the gallon of water, being careful to keep the mixture out of the pots. This may be done by turning them on their sides. In ten or twelve hours afterwards syringe the plants with clean water, by which time they should be free from every thrips.

USE OF BAMBOO STEMS IN LAYERING.

LE COMTE DE CASTILLON describes in the "Revue Horticole" one of the many interesting modes of layering employed by the Japanese in cases of strong branches, or those situated high on the stem; the basin formed by the joint of the large Bamboo which grows in that

country makes the stems convenient for this purpose. As will be seen by the sketch, the Bamboo layering-pot is so formed as to support itself firmly. There is, of course, soil in the vase formed by the joint, this soil being covered with Moss or small herbs, and kept moist.

BOUGAINVILLEAS AND THEIR CULTURE.

CONSIDERING the great beauty of these and their general usefulness either for furnishing cut flowers or for general decorative purposes as pot plants or roof climbers in stoves, it will, I think, be readily conceded by those well acquainted with them that they are not nearly so much grown as their merits deserve. Many have abandoned their cultivation under the erroneous idea that they are shy bloomers, whereas the reverse of this is the case, when they have the right treatment and are subjected to plenty of sunshine and light to ripen their wood. This, however, applies more to *B. speciosa*, that flowers on the young growth of the previous year, than to any other, and as this is the finest and most useful species, and one which requires different treatment from *B. glabra*, it may

be well to notice it first. There is probably no plant that is more tenacious of life or one which is more tractable and easy to cultivate than this

Bougainvillea speciosa.

It will stand extremes of heat and cold, and variations as regards moisture at the root that would prove fatal to any other plant with which I am acquainted. I have had it for weeks in a 12-in. pot standing in full sunshine without a drop of water being given it beyond what it got from syringing, and this treatment has invariably been attended with the best possible results, as it is only by checking over-luxuriant growth in this way and getting the wood thoroughly ripened, that it can be induced to put forth that lovely, rich, satiny-looking inflorescence for which it is so much admired. The secret of success with this plant is to have the roots under perfect control, and unless this is attended to, failure is inevitable, as it is impossible to restrict growth in any other way or to ripen it after it is formed. Those, therefore, who happen to have over-luxuriant plants of this species that do not produce flowers so freely as they may desire, should at once attack the roots and cut away any that appear to ramble far away or deep down in the soil beneath, and only leave such as are near home, as it is termed, and are furnished with plenty of fibre. This done, the next thing is to form a hard, impervious bottom which may be managed by mixing up a small quantity of quick-setting cement with some fine, clean gravel and spreading it under the ball of earth, which should then be bricked round, leaving only just sufficient room to contain a yard of soil at the most, as that will be ample for any plant required to cover the roof of a large house. Before filling in around the roots, it is important that the plant should be afforded free drainage, which may be best done by placing under it 6 in. or so of soft porous brick, broken into moderately small pieces, that will absorb any surplus water passing through the soil and give it back slowly for the roots to feed on. This interference below reducing, as it must necessarily do, a great number of the feeders, should be accompanied with a corresponding reduction of the top, which may be carried out by cutting away the greater portion of the side branches, leaving only sufficient to lay in to furnish the roof thinly and on these the flowering wood will be formed. The plant should, when filled in around the roots with some sharp sandy soil, receive a good soaking of warm water and be kept well syringed overhead till it starts into fresh growth, when a somewhat drier state of the atmosphere may be permitted, and plenty of air be afforded on all favourable occasions. Should the young shoots formed during the summer appear so thick as to overshadow or interfere with each other, thin them out, leaving them about 6 in. apart, but do not stop the ends of any remaining, as they will flower during their entire length and form festoons of great natural beauty. By the end of August or beginning of September a drier state at the root should be allowed, and water should be altogether withheld after the latter month till the blooming period is over, as it frequently happens that, instead of bringing the floral bracts to perfection, they shed the whole of them after the application of water, especially if the soil should happen to be cold at the time. In places where it can be arranged to have the roots near the heating apparatus, advantage should always be taken of such a position, as there is no plant fonder of a warm, dry bed during the winter than the *Bougainvillea speciosa*, or one that makes a better return for attention in that way. Although considered a stove plant, and one that will bear almost any amount of heat, it succeeds well in an intermediate-house, and may be grown as successfully there as anywhere else, but, wherever placed, it is essential that it be trained tolerably close up the glass, so as to have the full benefit of all the sun and light that can be afforded, and never shaded at any time. In cases where only a limited portion of the roof can be devoted to the culture of this very desirable plant, a 12-in. or 15-in. pot will contain plenty of soil to grow it to perfection and keep it in a perfect state of health for many years. A slate box is, however, in every way preferable, as it can be placed so as to fit in any corner immediately over a hot-water pipe, a position that will suit the roots exactly. A slate tub is also neater in appearance than a common earthen pot, and

therefore desirable on that account; but in whichever way the plant may be grown, it should have perfect drainage and a poor sandy loam firmly pressed in around the roots, otherwise the growth is apt to become unruly while the plant is young and full of vigour. With the roots under control in this way, it is an easy matter to administer stimulants in the form of liquid manure whenever necessary, a practice that is far better, in most cases, than affording rich soil at the outset. Those who are not in possession of this *Bougainvillea* will find the present a good time to start with it, as by getting it up to the roof to make its lateral growth early, a great display of flowers may be obtained next February if the system of cultivation detailed above be carried out. In order to get the plant up to the roof as quickly as possible, all side shoots should be kept nipped off as they appear, and every encouragement should be given to the leading one by tying it and training it properly till it has reached the desired length, when that, too, should be stopped, in order to induce side branches of form on which the inflorescence will be borne. Although

Bougainvillea glabra

is equal in value to the above as a roof climber, it is as a pot plant for exhibition purposes or conservatory or greenhouse decoration that it is most prized by cultivators, and when laden with its lovely, pale-pink-coloured bracts, it certainly is an object of great beauty, thoroughly deserving a place even in the most select collection. Planted out and treated as to root room much after the manner of *B. speciosa*, there is no end to its blooming capacity and the quantity of cut flowers which it affords from May to December, during the greater part of which time it is in full beauty, and is then quickly succeeded by the above-named variety, so that the two nearly girdle the year round with their richly coloured bracts. The treatment required by *B. glabra* differs materially from that necessary for the variety already touched on, both as regards watering and pruning, as the flowers are produced on the young wood immediately it is formed, and therefore the whole of the previous year's growth must be pruned away, except such as may be wanted for furnishing any vacant places that may exist in any part of the plant. This should now be done at once, and a soaking of warm water given, after which all that is necessary during the summer in the management of the top is to cut out all gross shoots as they appear, and to thin the remainder sufficiently to prevent them from encroaching on each other so as to shade the bloom or mar its effect. From December to April, the soil should be kept dry to afford it a rest, when if in a cool house, in which it may be grown most successfully, the leaves will fall off, but without affecting the health of the plant. For pot culture it is one of the most tractable things grown and readily conforms to any kind of training; it may be had in the pyramidal form, or as a standard, or trained to any kind of trellis, on which, if not too stiffly tied, it makes fine specimens and produces a striking effect. To get plants of this in early for conservatory decoration they should be pruned at once, cutting away all weak, superfluous wood, and shortening back the stronger to be tied thinly and regularly over the trellis. When pruned they should be partly shaken out of the old soil and repotted in good fibry loam either in the same-sized pots or others of larger dimensions, according to the requirements of the plants, and the purposes for which they are wanted; this done they are ready for starting into growth, which should be effected by placing them in any forcing house at work where they can get a gentle syringing, and have plenty of light in order to keep the young shoots short-jointed and strong. If the soil be moderately moist at the time of potting as it should be, very little, if any water will be required till they get well into leaf, after which they will need water in increased quantities as growth proceeds and the pots fill with roots, when liquid manure will be found of great assistance to them, and may be given at each alternate watering. If grown on stages amongst other plants, they should be set on inverted pots, with their heads well up to the glass, where they can be fully exposed to the sun and have plenty of air on all favourable occasions. Treated in this way, every shoot will flower from the base to the summit of the plant, and the floral bracts will possess more colour and substance than would be the case under less favourable condi-

tions. Any that are required for conservatory decoration should gradually receive more air, so as to inure them to the change by degrees, and when in that structure they should be so placed as to have but little shade, except what may be afforded by the roof climbers kept within bounds by regular and proper thinning. *B. glabra* is so hardy, compared with the other, that it will winter with safety in a temperature not lower than 45° if kept dry at the roots, and it is on this account a very desirable plant to cultivate as it may be stored away in any warm shed or cellar along with *Fuchsias* and similar plants till the time comes round for starting them again. Both this and *B. speciosa* may be readily increased by taking off the short young wood with a heel, and inserting it in sandy soil in the propagating box, where they can get a brisk heat and be kept close for a time. Fortunately, neither are much affected by insects, their only enemy being green fly, and this is merely troublesome while the shoots are young and tender, and the plants are just putting forth those lovely floral bracts for which they are so highly prized. Just at that time they require close watching, as the aphides insinuate themselves among the leaflets long before they begin to unfold, and damage their appearance. It is therefore advisable to give the house a whiff of Tobacco smoke, whether their presence is observed or not, for sooner or later they are sure to make their appearance, unless timely precaution be taken to prevent them. S. J.

THE FUCHSIA AS A CLIMBER.

WERE the *Fuchsia* to appear at the present time as a new introduction, it would probably be welcomed as a glorious acquisition to our climbing plants, notwithstanding the wealth of fine subjects we now possess in that way; but, as it happens to be common, it is rarely now planted as a conservatory climber. Yet it can hardly be surpassed for that purpose. The *Taesonja Van Volxemi* is a splendid and very popular climber, but it has neither such wealth of flowers nor contrast of colour as the *Fuchsia*, and it certainly is not so accommodating as regards temperature. We have some old *Fuchsias* growing up the rafters of one of the houses here, which we are sure need less attention than any of our other climbers, and which produce no end of flowers between May and November. The shoots hang down 5 ft. and 6 ft. from the roof, laden with their drooping flowers, and whole bundles of such shoots are cut off during the summer to decorate glasses and vases that have to be trimmed with drooping flowers and foliage. The plants have stems like old Vines, and are growing with their roots outside, no one exactly knows where, but it is believed they are luxuriating in the stiff loam under the foundations. In December the shoots are all cut close back to the stem, just like spur-pruned Vines, and during summer they are not tied or trained in any way, unless they droop so low down as to be an inconvenience, when they are looped up. The *Fuchsia* is an astonishing grower when planted out, and young plants run up the rafters in a couple of years or so. Our trees—for so they may be called—have young shoots upon them now 18 in. long, though they are growing in a cold house, where the fire is never lighted except to exclude frost. The *Fuchsia* will grow vigorously in any common garden soil, and if it be rich all the better, provided the plants have room, air, and light, and are allowed to extend during the summer. As regards training, the best plan is to take one leading shoot up the rafter or wire, and let it grow as much as it will (a *Fuchsia* will sometimes grow 10 ft. or more in a season), at the same time permitting all side branches or laterals to grow without stopping also. These are always produced regularly and abundantly along the main stem, under favourable conditions; and they will grow several feet long, and flower along a good part of their length, though the blooms are produced in greatest quantity at the points of the shoots. No lateral training should be attempted; the leading shoot only should be guided by tying it to the wire, but all the others should hang down from the roof. Now is a good time to plant, and if old pot plants with tall stems be available for the purpose, they are better than young ones, as they afford a good start. The plants need only be shaken out and planted like Vines; and if provision be made for them to root through or under the wall to the outside, all the better. The usefulness of the *Fuchsia* for cutting for indoor decorative purposes has been already alluded to; but a word more may be added on that point. The more free-growing varieties make much longer and suppler shoots when planted out than they do in pots, and they will bear bending like Willows. We cut them off their entire length for vase work, sticking them in round the edges of

tall vases, from which they droop in a graceful and showy manner; and they mix well with almost any other flowers. Sometimes, when used as a drapery for large vases containing groups of plants, we have just stuck the shoots into the flower pots and let them hang over. The soil in the pots being moist keeps them fresh for some days, even in very dry rooms; and when they begin to droop they are renewed. The plants are nothing the worse for the thinning, and they grow fast enough to afford a good supply of shoots for cutting. There are two or three old bright scarlet varieties of the *Fuchsia*, the names of which we do not know, that make good climbers, and they are often seen growing in that way; but almost any variety will succeed. Strong-growing, free-flowering sorts should, however, be chosen for the purpose. It may just be stated that tall plants grown in pots or tubs may be grown as successfully against a wall out-of-doors as under glass, provided they are protected in winter, or sheltered after being pruned in some cold shed or house till about the month of April, when they may be put out.—“Field.”

LACED AURICULAS.

I AM careful to distinguish “laced” flowers from those so well known to Auricula growers as “edged” flowers, because those to which I now direct attention have little in common with the latter. We are indebted to the Messrs. Vilmorin, of Paris, for the charming strain of Auriculas that include the laced flowers, and although even the best of them may not be perfect show varieties, yet they have qualities that show a capacity for improvement. They are apparently allied to the Alpine section, and size and good form characterise many of the best kinds, whilst the markings vary both in hue and density. Some have the belting as clearly defined as in the laced Polyanthus, others have it partially suffused into the body, but of course in a strain of laced flowers, clear and perfect markings would be indispensable. In a batch of young plants raised from seed sown last spring and just now coming into flower, one has a clear lemon centre, surrounded with a ground of heavy maroon, broadly laced with a clear margin of pale peach. Another has a ground of deep purple shading off into a margin of pale mauve. The ground of another is almost black maroon laced with greyish buff. Another has a lacing of bright buff much like that of a gold-edged Polyanthus; another has a lacing of lavender; and in another there are three distinct tints, viz., ground colour, deep maroon clearly belted with pale purple, and laced with French white. The seed was not sown until late in the spring, and the seedlings were pricked out into a soil bed in a large roomy house for the winter, where they were quite at home, and evidently have done better than those kept in pots; all are now lifted for convenience into small pots, and the selected plants will thus be kept for future care and cultivation, the remainder being planted out in the open ground. The idea is prevalent that the winter is detrimental to the Auricula in the open ground, and probably this is the case with choice kinds, but robust, showy sorts, such as this laced strain, will do well as border plants, and perhaps be more in danger from excessive drought than cold. Where the open ground is decidedly unsuitable to the winter growth of the Auricula, it should be wintered in cold frames, and if the plants be lifted in the autumn, potted, and kept moderately dry until the bloom-buds appear, they will be none the worse for removal. For showy spring beds these Auriculas are well adapted, as they furnish much variety and beauty without displaying a mass of colour. If the plants can be transferred from some cool border in the autumn to the bed direct so much the better; but if the housing in winter be indispensable, then the plants should be plunged in the pots in the bed until the bloom is past, when they can be returned to the frame or any other cool situation.—A. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Striking Gloxinias in Cocoa-nut Fibre.—The leaf-stalks of Gloxinias strike readily in Cocoa-nut fibre placed on a bed in which there is a gentle warmth. When rooted, the bulbs and roots are more easily and safely removed from among this material than from soil.—S.

Blue Greenhouse Climbers.—These are comparatively scarce, but we have a good and really useful one as far as cut bloom is concerned in *Konnedya australis*. It commences to bloom in a cool house in March, and lasts in good condition for a considerable length of time. A large plant of it trained up to the roof of the conservatory at Kew, is now laden with clusters of bright blue pea-shaped blossoms, which, associated with flowers of other colours where they grow and also in a cut state in vases, are exceedingly effective.—C. S.

Forced Roses.—There is one Rose which I always admire, whether forced or otherwise, and that is Charles Lawson, the fine form and lovely colour of which render it welcome either in spring or summer. Plants of it well established, and brought on gradually for cut bloom and conservatory decoration during the spring months, would be difficult to excel either for quality or quantity of produce by any Rose in cultivation.—J. GROOM, *Henham*.

AN “INTERNATIONAL” FLOWER SHOW IN HOLLAND.

WE have had too many “international” exhibitions of late years. Still they seem to increase, though as at present managed they must fall into disrepute. They are seldom really international in character; they are frequently originated in the interest of local or partial commercial interests, and they usually take place at a time of year when it is impossible to judge of the really important and instructive horticultural productions of the countries in which they occur. The time of flowering of some class of plants grown extensively by the local nurserymen usually governs the time of opening. Nobody can suppose that Azaleas, for example, have any but a trifling importance in the horticulture of a country; yet to see such (a familiar sight enough) plants in their best dress a number of weary pilgrims are induced to make long journeys at a time when there is not a green leaf to be seen, and when it is often impossible to see anything beyond the show itself. An international exhibition, to be really useful, should be held at a time when the important products of a country may be seen in perfection. It is generally unwise to hold them at times when only one branch of horticulture can be profitably represented. Occasionally the presence of the “great world” in a large centre like London must govern the season of the holding of an exhibition for financial reasons, but this can only apply to London or Paris. Nothing could be more instructive and beautiful than a representative collection of fruit in such a country as Holland, Belgium, Germany, or Northern France; yet these shows are held at a time when fruit is not to be seen. A great fruit show would not merely be of far more importance to any of the said countries than any group of ornamental plants, but it could not fail to be of great value to people like ourselves inhabiting similar countries. Local varieties of merit would be made known, and our knowledge of the varieties and the modes of culture that succeed best under adverse conditions would be increased. But apart from such considerations the beauty of a fine collection of fruit will sometimes appeal to us as much as that of flowers. M. C. Ballet once showed a collection of hardy fruits in Paris which for beauty alone was as striking as anything ever seen at a flower show, and in autumn or in summer one could also visit the gardens and orchards, and see the modes of culture. It is scarcely necessary to say here that we owed some of our best vegetables, in the first instance, to Continental countries, the culture in which is often superior; the shows are held at a time when few vegetables are to be seen, and when their culture in private or in market gardens cannot be observed. As to trees and shrubs, and even country seats, they are seen to great disadvantage in spring even if the weather be favourable; it is generally, as everybody knows, the reverse of that in northern Europe in April. Encouraging reports of the last great show at Amsterdam led us to follow the example of others and cross the brown waters of Holland, in the hope of finding some interest in the International Show opened April 12, at Amsterdam—a more ill-managed or less instructive affair it would be difficult to imagine! This was not so much from deficiency of products as from want of plan or energy of management, though, as regards the subjects shown, there was nothing very remarkable to speak of. Such as it was it appeared much less owing to the scattered arrangement and feeble plan; a large and suitable building (the Crystal Palace of the town) should have contained all the important groups and classes of tender plants; only a few groups of Palms, however, were placed in it, all the rest of the very suitable space being filled with a variety of objects having little or nothing to do with horticulture, such as wild animals (cast life-size) in coloured plaster, machinery, cutlery, sewing machines, &c. Various fine collections of plants which ought to have been arranged in this exhibition were scattered about in two different gardens (near the main building) in such a way that all good effect was lost. Some persons, indeed, only saw one of the gardens, owing to their being separated from each other in an awkward manner by the main building and by a road. This is all the more to be regretted when it is considered that few cities in Europe have a more suitable structure for the holding of a great flower show than this building, where such good opportunities were lost. In the garden where plants more or less tender were exposed

in structures wholly or partially open to the April zephyrs of the North Sea, were also arranged fruit trees, shrubs, and evergreens in considerable quantities; for these and like subjects the gardens might have been wholly reserved with advantage. The defective nature of the plan, however, was less noticeable than the needless waste of time in opening the show. The work of arranging and judging the plants and opening the show, which usually occupies a busy morning in England, was here scattered over several days. With us the result is that we see the flowers in all their freshness; here on the morning of the opening day many of them were so withered, that those who did not know they were martyrs to needless delay and exposure, wondered why they were ever sent to a flower show. As instructive or interesting features, the show was very poor from our point of view; nor could it well be otherwise from reasons before mentioned. There were the usual graceful Palms, &c., and as Holland is the land of bulbs, there was a good show of bulbs; but this was certainly no better than is occasionally seen in London in spring, one held during the past spring at Kensington being generally considered to be better. From the point of view of indoor gardening, it was interesting to notice the great number of Hyacinths grown to perfection in glasses. Bedding-out and "panels" of Alpine and various other plants of the most miserable description were seen here and there about the grounds. Among these it was amusing to notice miniature copies of the mud edgings which give such a distinguished aspect to some of our London parks and gardens. Numerous herbaceous and Alpine plants were shown without flowers or with few. As these plants are before all others the most floriferous, such exhibiting is calculated to bring them into unmerited disrepute. Roses forced were seen in some abundance—tall and poor standard plants, scraggy bouquets held on the end of broomsticks. The best plants in the show (new plants, Orchids, Ferns, and mixed collections) were brought all the way from London by Mr. B. S. Williams. Notwithstanding the delay and the long journey the plants seemed as fresh as if at home in London. For these well-grown and choice collections Mr. Williams obtained no less than eight gold medals and the first prize for new plants. Fruit trees were shown in sufficient abundance in the ground to show that the best methods of training known to the French are practised to good effect here. Among the few interesting foreign displays was that of beautiful and well-preserved fruit from Turin. These showed well the capacities of Italy for fruit culture. It would be interesting to learn how so many fine Apples are so long and well preserved. The collection of artificial fruit from Turin was also very remarkable, and the best and most accurately formed we have seen. Artificial flowers have no charm for us, but in the case of fruits good models offer us the best of all means of identification; therefore collections of them would be valuable in agricultural and horticultural schools, and in local and other museums.

To award the prizes in the various classes (a labour which could be got through well by a dozen good men in three hours) an army of between 300 and 400 jurors from all parts of Europe were invited. In illustration of the management of the show, we may mention that in some cases the cards indicating the various prizes were not in their places until two days after the jurors had completed their awards. There was no printed list of prizes obtainable in any language on the day of awarding the prizes or the day after. On the opening day the structures containing the newer and choicer plants were closed until His Majesty had walked round. As this did not happen till late in the day, there appeared to be no reason why the plants should be so hidden away. Those who wished to see the collections in the morning of the only day when they might be seen to the best advantage were in this way deprived of the opportunity of doing so.

Coloured Wild Primroses.—In a meadow near here are numerous Primroses of various shades of colour, varying from white to bright pink. As they seldom vary from the original type in woodlands, is this the result of the land being more or less matted or cultivated?—J. GROOM, *Hobham*.

Early Roses.—If the weather keep favourable we shall have Hybrid Perpetual Rose blooms in quantity out-of-doors early in May. The shoots are now about 1 ft. long and show fine strong buds. To have Roses thus early the trees must be pruned in November and the plants must occupy a very sheltered position.—A NORTHERN GARDENER.

HAPPY MARRIAGES.

THE numerous hardy climbers which we possess are very rarely seen to advantage, owing to their being stilly trained against walls. Indeed, the greater number of hardy climbers have gone out of cultivation, owing to there being no general idea as to their proper use. One of the happiest of all ways of using them is that of training them in a free manner against trees; in this way many beautiful effects may be secured. The trees must not, of course, be those crowded in shrubberies, but standing on the turf. Established trees have usually exhausted the ground near their base, which may, however, afford nutriment to a hardy climbing shrub. In some low trees the graceful companion may garland their heads; in tall ones the stem only may at first be adorned. But some vigorous climbers could in time ascend the tallest trees, and we can conceive of nothing more beautiful than a veil of such a one as Clematis montana suspended from the branch of a tall tree. A whole host of lovely plants may be seen to great advantage in this way, apart from the well-known and popular climbing plants. There are, for example, many species of Clematis which have never come into cultivation, but which are quite as beautiful as climbers can be, and which may be favourably seen in this way. The same may be said of the Honeysuckles, wild Vines, and various other families of which the names may be found in catalogues. In consequence, however, of the fact that no system

Japanese Honeysuckle on Stem of Birch tree.

of growing these plants to advantage has ever been carried out in our gardens, nurseries are by no means so rich in them as could be desired. Much of the northern tree and shrub world is garlanded with creepers, which may be grown in the way we suggest and in similar ways, as, for example, on banks and in hedgerows. The naked stems of the trees in our pleasure grounds, however, have the first claim on our attention in planting garlands. There would seldom be need to fear injury to established trees.

Tomato Leaves & Insects.—"I planted a Peach orchard," writes M. Siroy, of the Society of Horticulture, Valparaiso, "and the trees grew well and strongly. They had but just commenced to bud when they were invaded by the Curculio, which was followed, as frequently happens, by ants. Having cut some Tomatoes, the idea occurred to me that by placing some of the leaves around the trunks and branches of the Peach trees, I might preserve them from the rays of the sun, which were very powerful. My surprise was great on the following day to find the trees entirely free from insects, not one remaining, except here and there where a curled leaf prevented the Tomato from exercising its influence. These leaves I carefully unrolled, placing upon them fresh ones from the Tomato, with the result of banishing the last insect, and enabling the trees to grow with luxuriance. Wishing to carry still further my experiment, I steeped in water some fresh leaves of the Tomato, and with the infusion sprinkled other plants, Roses and Oranges. In two days these were also free from the innumerable insects which covered them, and I felt sure that, had I used the same means with my Melon patch, I should have met with the same result."

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 18.

THIS meeting was one of the most attractive that has been held in the gardens at South Kensington during the past two or three years, and although the produce shown was, for the most part, simply such as is daily supplied to Covent Garden Market, yet the exhibition was a most successful one. Mr. Webber's collection of fruit was very attractive, the basket of Lady Downes Grapes which it contained being in wonderfully good condition, and the examples of new Black Hamburgs were far above the average, as were also Apples, Pears, Bananas, and Pine-apples. Messrs. Draper & Son sent a large collection of imported vegetables and fruit. Mr. Foupert (the only representative of the London market gardeners) furnished a good collection of Salading and other vegetables, and Mr. Domelle, of Guernsey, well represented the culture of early Potatoes (one of the principal industries in the Channel Islands) by sending six baskets of Myatt's Ash-leaf Potatoes in splendid condition, large smooth tubers, which could scarcely have been surpassed even in the height of the Potato season. Among cultivators of decorative plants Mr. Herbst had one of the most effective groups shown, his Lilies of the Valley and *Primula cortusoides* being most tastefully grouped; while Mr. Beckwith's *Pelargoniums* were simply perfect as decorative plants, both as regards foliage and bloom. Mr. Reeves, of Acton, had a well-arranged and extensive collection of Palms, *Dracenas*, *Arum Lilies*, Tulips, *Spiræas*, and other plants; and Messrs. Wright, Mr. H. B. Smith, and other growers more fully alluded to elsewhere, also contributed excellent collections; Messrs. Rollisson & Sons, Azaleas; and the Rhododendrons and Roses in pots from Messrs. Lane & Son, were perfect masses of bloom. Messrs. Osborn, Mr. B. S. Williams, and Mr. Wills, had also large and varied groups of decorative plants, and Messrs. Barr & Sugden showed a large and varied group of cut flowers of *Narcissus*, tastefully arranged on a background of Ferns and Lycopods; these embracing, as they did, about fifty distinct kinds, attracted much attention. Altogether, the display was most interesting, and one which reflected much credit on all concerned in its production.

First-class Certificates.—These were awarded to the following new and rare plants:—

***Pelargonium*, Duchess of Bedford** (G. Beckwith & Sons).—A fancy decorative variety, pure white with a pink spot on the upper petals, all the latter being, moreover, elegantly frilled. It grows freely and will doubtless soon be popular as a market plant.

Primula cortusoides purpurea (R. Dean).—A slender-habited variety bearing graceful umbels of dark bluish-purple flowers. It is a distinct and effective kind, and will be useful for contrasting with pale-tinted or white kinds.

Primula cortusoides maxima (R. Dean).—A very floriferous variety, bearing umbels of large pendent flowers and deep rosy buds. The backs of the petals are of a deep rosy-lilac tint; the flowers as seen from the front are nearly white.

Primula cortusoides cœrulea (R. Dean).—A large-flowered, white variety, delicately tinted with pale cœrulean blue. It well deserves culture as a decorative plant along with those just named and a richly-tinted variety of the same batch named *laciniata*, which was certificated last year.

***Polyanthus*, Duke of Wellington** (G. Smith).—A remarkable gold-laced variety, having nearly black markings on a pale golden ground. This is very attractive, and one which deserves a place in all gardens in which gold-laced *Polyanthuses* are still grown.

Tulipa Greigi (H. J. Elwes).—A noble hardy Tulip, bearing vivid orange or vermilion-tinted flowers, each petal having a bold blackish blotch at its base. The glaucous foliage is spotted and blotched with purplish brown. A most showy hardy bulb, well worth culture in all good collections.

Miscellaneous Collections.—Mr. B. S. Williams sent *Acalypha musaica* and a new spiral-leaved *Croton* named Prince of Wales. Messrs. E. G. Henderson & Sons furnished two new varieties of *Coleus*, one of which, named Pine-apple Beauty, promises to become a popular decorative plant. It is compact in habit, the basal halves of its golden-yellow leaves being of a rich maroon tint. It is distinct from a somewhat similar variety named Lady Burrell, the whole under-surface of the leaf being yellow. Messrs. H. Lane & Sons, of Berkhamsted, sent a large and well-flowered group of *Roses* in 9-in. pots. Among them we noted Madame Lacharme, the new white variety; General Jacqueminot, one of the oldest and best of fiery crimson; Elie Morel, a soft peach-coloured variety; Queen of Waltham; and others of equal merit. From the same firm came six well-grown *Azaleas* in dense pyramids of flowers and foliage 4 ft. in height. Messrs. Lane & Sons likewise contributed a large and gorgeously-flowered group of *Rhododendrons*, one of which, named The Queen, a delicate blush-tinted kind with a yellow spot, struck us as being remarkably handsome; and the same remark also applies to Mrs. R. Holford, a bright rosy variety with crisped petals. Messrs. Osborn & Sons, Fulham, sent a small but attractive group of new Palms, Ferns, and other decorative plants, among which we noted a very large-spined variety of *Anthurium Scherzerianum*, the colour of which was more vivid than is usually the case in these large-spined kinds. Among the more distinct Palms in this group *Licuala horrida* deserves notice, its peltate leaves being slit into windmill-like lobes. This group was a semi-circular one, and fringed with *Isolepis gracilis* and *Adian-*

tum Farleyense. Mr. John Wills had a similar group of large *Areca*s, *Kentias*, and other rare Palms, arching gracefully over a mass of *Azaleas*, *Dendrobium nobile*, scarlet *Pelargoniums*, and Lily of the Valley, the whole fringed with *Isolepis*, *Dracenas*, and *Begonias* of various kinds. Mr. B. S. Williams contributed a large and varied collection of new and rare plants, among which we noted *Echmea Mariæ Reginae*, in habit something like a broad-leaved Pine-apple, the inflorescence being graced with magenta-coloured bracts. A pair of well-bloomed plants of *Azalea amœna* were very attractive, and among the *Orchids* were a richly-marked form of *Odontoglossum triumphans* and a plant of the new *Phalaenopsis Manni*. Mr. J. Aldous, Gloucester Road, South Kensington, showed a group of *Azaleas*, *Heaths*, *Calceolarias*, and other decorative plants, among which were some well-grown pots of *Rhodanthe Manglesi* and pink *Hydrangea*. Messrs. Crocher & Boller, 73, South Row, Kensal New Town, sent a collection of miniature succulents of various kinds, tastefully arranged along with Ferns and other plants. Messrs. W. Rollisson & Sons furnished about two dozen floriferous plants of *Azaleas*, among which were some of the newer Continental kinds, trained in the form of dwarf standards with semi-circular heads about 2 ft. across. Among these we noted *Mdlle. Van Houtte*, a semi-double white, rosy-striped form of good size and substance; Charles Leirens, double scarlet, very vivid; *Gloire de Belgique*, white; President Ghellinek de Walle, carmine-rose; and others equally good. Mr. R. Dean sent a mixed group of *Primroses*, laced *Auriculas*, *Daisies*, and *Forget-me-nots*, all in admirable condition; also examples of golden, crimson-maroon, and brindled single *Wallflowers*, now so largely grown in London market gardens for spring flowers. From the same exhibitor came a showy group of seedling forms of *Primula cortusoides*, varying in colour from white, through all the shades of rose and lilac, to bluish-purple. Messrs. Barr & Sugden contributed about fifty varieties of new seedling and other *Narcissi*, some of the forms being very distinct and effective as garden plants, and others curious and interesting as being hybrids of curious structure. Among these fresh and charming flowers we noted some handsome seedling forms of *N. incomparabilis* and *N. Macleayi*, and two varieties of *N. triandrus*, one with a short white cup and clear sulphur-yellow reflexed petals being named *pulehellus*; another having a longer cup and very narrow petals, both cup and segments being of a creamy-white colour, and which further differ from the last in only bearing a solitary flower on each scape, looks like one of the links between *N. triandrus* and the rare *N. calathinus*. Some white forms of the *N. incomparabilis* group had lengthened yellow cups finished with orange-vermillion, and were very showy. This collection of *Narcissi* was one of the most extensive and complete ever exhibited at one time, and was much admired.

Covent Garden Produce.—The following collections of decorative plants were contributed by the principal cultivators who supply Covent Garden market, and, taken generally, were remarkable examples of good culture and effective arrangement. Messrs. H. R. and G. Wright, Turner Road, Lee, contributed a well-grown collection of Palms, Ferns, *Orchids*, and other decorative plants. Among the *Orchids* was a good specimen of *Oncidium sarcoodes*, with rich brown-blotched golden flowers, and a five-flowered plant of the snowy white *Cypripedium niveum*. Mr. George Poulton, Fountain Nursery, Edmonton, sent a batch of about 150 well-grown plants of *Spiræa (Hoteia) japonica*, bushy little plants in 6-in. pots. Mr. James Puttick, Park Road, Acton, showed a large group of double and single-flowered *Zonal Pelargoniums* of various colours, mixed with bushy, well-flowered plants of the large-flowered kinds, the whole tastefully margined with *Mignonette*, purple-flowered *Stocks*, and scented *Stag's-horn Pelargoniums*. Messrs. W. & A. Brown, of Hendon, furnished a remarkably well-arranged group of large-flowered and *Zonal Pelargoniums*, interspersed with well-flowered plants of the old-fashioned but ever welcome *Fairy Rose*, the whole being fringed with *Forget-me-nots*, hardy *Polystichums* and other Ferns, *Tricolor Pelargoniums*, and a remarkably compact and handsome dwarf rosy-flowered *Silene*. Mr. H. B. Smith, of the Ealing Dean Nursery, sent a well-grown collection of Palms, including a white variegated form of *Lantana borbonica*, coloured-leaved *Dracenas*, *Phormium tenax variegatum*, silvery-striped *Pandanus*, and Ferns, the latter including good plants of *Adiantum Farleyense* and the gossamer-like *A. gracillimum*. Messrs. J. & J. Hayes, of Edmonton, exhibited an extensive mixed group of scarlet *Pelargoniums*, purple, blue, and rosy *Cinerarias*, pink and white *Heaths*, *Cytisus fragrans*, *Fuchsias*, and Ferns—all well-grown plants in 6-in. pots, admirably suited for decorative purposes. This group was one of the largest in the show, being 40 yards in length and some 5 ft. in width. Mr. H. Herbst, of the Richmond Road Nurseries, Kew, sent one of the largest and most tastefully-arranged groups exhibited. It contained graceful *Areca*s—especially one named *A. Herbsti*—and other young seedling Palms; the snowy-white *Spiræa japonica*, and banks of Lily of the Valley and crimson *Azaleas*. The Lily of the Valley in this group were remarkable examples of good culture, and were much enhanced in beauty by being set in a frame as it were of the rich carmine-purple *Primula cortusoides amœna*. Messrs. Brookes & Gallop, 195, Western Road, Brighton, contributed a large basket of a remarkably vigorous *Mignonette* named Miles' New Hybrid Spiral. The flower-spikes are from 4 in. to 6 in. in length, and well furnished with blooms. Mr. Henry Garnett, 131, West Street, Sheffield, sent a golden-leaved form of common *Musk*; and a group of cut flowers of seedling fancy *Primroses* came from Mr. W. Culverwell, Thorpe Perrow. Several attractive stands of Alpine, show, and yellow-flowered *Auriculas* came from Mr. Charles Turner, of Slough. Mr. John Reeves, of Acton, showed a large group of decorative plants in excellent condition neatly arranged in panels

in which Mignonette, Lily of the Valley, crimson Fuchsias, Gardenias, Heliotropes, and pot Roses were well represented. A batch of pink Hydrangeas was also very showy, and the same may be said of a well-blended bank of fancy and other decorative Pelargoniums, single Tulips, double white Chinese Primroses and *Spirea japonica*, to which an irregular line of tall Palms and white Arum Lilies made a most effective background. Messrs. Hawkins and Bennett, Lily Gardens, Twickenham, sent a large group of pink, white, and scarlet Zonal Pelargoniums, bushy little plants in 6-in. pots, and remarkably well-bloomed. A panel in this group was effectively filled with clusters of cut Pelargonium flowers, white, rose, and scarlet, set in a bed of fresh green Moss and Maiden-hair Fern. Another large bank of Dracenas, Palms, and Ferns, brightened up with *Cytisus fragrans* and *Spirea japonica*, was a noticeable feature in the show. Messrs. G. Beckwith & Son, of Tottenham, exhibited a bank of decorative Pelargoniums about 30 yards in length and 10 ft. in width; it contained several hundred of well-grown plants, all in 5-in. or 6-in. pots, and consisting of fancy, double, and show kinds, a little variety and fragrance were afforded by a group of Heliotropes, among which were several dark purple and desirable sorts for cut blooms. Messrs. Hooper & Co., Central Avenue, Covent Garden, contributed a choice collection of Palms, Ferns, and other fine-foliated plants in excellent condition, and from the same exhibitors came a collection of dried Grasses and Immortelles, in the form of well-arranged wreaths and bouquets.

Floral Decorations.—Bouquets were limited in number, and the quality was scarcely what might have been expected from Covent Garden. The best were shown by Mr. James Bromwich, Buckingham Palace Road, whose bride's bouquet was one of the most tasteful and artistic productions which we have seen. It consisted of white Camellias, buds of the Tea Rose *Niphetos*, Lily of the Valley, double white Chinese Primulas, Stephanotis, Orange blossom, and white Bouvardia, the whole fringed most delicately with Maiden-hair. Two or three sprays of the foliage and unopened buds of the Fairy Rose were introduced with excellent effect. Mr. Bromwich's ball-room bouquet was also a tasteful combination; for this and the one just named a silver medal was awarded, and they were also highly commended. Messrs. Walter Wood, Parmeley & Co., Albert Gate, Knightsbridge, also received a silver medal for two well-arranged bouquets, but they were too large and contained too much Fern. Mr. T. A. Dickson received a bronze medal for the best bouquet of any kind; he sent three well-arranged examples, composed of Tea Rose, *Niphetos*, white Lilac, orange flowers, Heath, Stephanotis, Orchids, and other choice flowers, fringed with Maiden-hair Fern. Mr. J. Aldous furnished a well-arranged vase of white Lilac, and forced Solomon's Seal, a spray or two of *Pteris serrulata* being used with excellent effect, the whole being fringed with *Selaginella*, and *Isolepis gracilis*. Mr. Aldous also sent three bouquets of choice flowers. Messrs. Walter Wood, Parmeley & Co. had a tastefully decorated set of dinner-table vases; and Mr. W. Stone, Covent Garden, sent three bouquets of Roses, Orchids, and other choice flowers.

Fruit and Vegetables.—A fine collection of imported and home-grown fruit came from Messrs. Webber & Son, of the Central Avenue, Covent Garden, who furnished among other things a basket of Easter Beurré Pears from California, of good size and not only in a perfect state of preservation, but delicious in flavour. Associated with these were also clusters of Bananas from Madeira, large, clean, and perfectly ripe; Blood Oranges from Valencia, and ordinary Oranges from the same port, together with Mandarin Oranges from Sicily; large and highly-coloured, conical Shaddocks from the West Indies; six smooth-leaved Cayenne Pines, two being of home growth and four from the Azores; between these the difference in shape and colour was remarkable, the English fruit being tall and pale, while the St. Michael fruit were sub-globose and of a rich orange-vermilion tint. Figs fresh and forced of course; early Beatrice Peaches of home growth; new Strawberries, large in size and of good flavour; Grapes both new and old; and a good basket of Apples made up perhaps the finest collection of fruit ever seen at this season. The Grapes consisted of new Black Hamburgs fine both in bunch and berry; White Chasselas, and Lady Downes, the latter quite plump and fresh. Messrs. Draper & Son sent Valencia and Blood Oranges, Tangerine Oranges from Palermo, Lemons, West Indian Pomeloes, Lady Apples of French growth, and Chasselas Grapes from Montreuil, rather shrivelled, but excellent in flavour. Along with these also came Easter Beurré Pears from Meaux, and Calville Blanc, Dien Donné, and Russet Apples from Montreuil, and excellent fresh Tomatoes from Toulon. The same exhibitors all showed a good collection of vegetables, among which we noticed excellent Endive, Cos and Cabbage Lettuces of French growth, Asparagus of good quality from Toulouse, both green and purple-topped varieties, and Globe Artichokes from Avignon, and the true long French Turnip of the Paris market gardens, together with excellent Cauliflowers from Angers. The Short Horn Carrot of the Paris markets, so delicious in soups, &c., was also shown by this firm, together with French Beans from Toulouse, Cardoons from Paris, and Green Peas from Mentone—the whole forming a most interesting collection of foreign produce. Mr. Poupert, of Covent Garden, sent Lettuces, Radishes, Endive, Green Mint, Early Cabbage, fresh young Onions, Seakale, Parsley, and Rhubarb, all good in quality. Mr. N. Domicille, of Guernsey, showed six baskets of Myatt's Ashleaf Kidney Potatoes, remarkably large and clear, and far superior to Maltese, Algerian, or other produce of the same kind. Messrs. Beer and Sams, Chesswood Gardens, Worthing, sent a box of Telegraph Cucumbers. Mr. R. Price, of Cookham, furnished a large box of ripe Strawberries in good condition. Mr. Matthew Newman, of Harlington, London, sent plants of a yellow

variegated Strawberry, and also specimens of a good strain of single crimson-flowered Wallflower; likewise Violets of the Russian variety, and double white and sulphur-tinted Primroses, which are grown in quantity for Covent Garden Market. Mr. W. Tilbery, gardener to the Duke of Portland at Welbeck, contributed, specimens of three late-keeping Grapes, namely, Lady Downes, Royal Vineyard, and a black variety raised at Welbeck, and said to be a cross between Lady Downes and West St. Peters. It is a medium-sized variety of vinous flavour, the examples shown being slightly shrivelled. A dish of seedling Apple, named Baron Liebig, came from Mr. James Pink, Lees Court, Faversham. Mr. H. Frond, gardener to J. Balguy, Esq., Hawley Place, Dartford, Kent, showed a dish of Early Rose Potatoes in good condition; and Mr. Wm. Rapley, gardener to R. Hindson, Esq., Clapham Common, sent a brace of Telegraph Cucumbers; and a fasciated stem of the same variety, having five good fruit, came from Mr. Bennett, Rablay.

Miscellaneous.—Messrs. Barr & Sugden exhibited several tastefully-arranged Fern and window cases, to which a first prize was awarded. Mr. Jas. Bromwich and Messrs. Dick Radclyffe had also some well-filled cases. A new saddle boiler, of improved construction, was exhibited by Messrs. McLaren & Co., 174, Upper Thames Street, E.C.; the one shown was of large size, and attracted a good deal of attention. Messrs. Waite, Burnell, & Huggins sent several examples of a new American lawn mower, somewhat similar to the Archimedean in principle, and said to work well.

ROYAL BOTANIC SOCIETY.

APRIL 18.

THIS was a better show than might have been expected, considering that one was held on the same day at South Kensington. Messrs. Veitch & Son and Mr. Charles Turner exhibited finely-flowered collections of pot Roses. Among Messrs. Veitch's plants were good examples of Madame Willermoz, Paul Verdier, Camille Bernardin, President, Duke of Edinburgh, and a fine pyramidal specimen of Madame de St. Joseph, the latter bearing upwards of fifty large blossoms. Mr. Turner furnished neatly-grown plants of Miss Hassard, Maréchal Robert, Madame Ferdinand Jamin, and remarkably fine specimens of Souvenir d'un Ami, Celine Forrester, and Madame Lacharme, the latter bearing very large and delicately-tinted flowers. Roses in pots were also shown by Messrs. Paul, the Old Nurseries, Cheshunt, who had healthy, well-flowered plants of Madame Victor Verdier, La France, Beauty of Waltham, and Cheshunt Hybrid. Two excellent boxes of cut Roses were exhibited by Mr. J. Walker, nurseryman, Thame, Oxon; one consisted entirely of Maréchal Niel, the blooms of which were large and beautifully coloured. A new Hybrid Perpetual Rose came from Messrs. Paul & Son; it was named Marguerite Brassac, and is a large, well-formed, dark crimson flower of the Charles Lefebvre type. Collections of Azaleas were contributed by Mr. Turner, Slough; Messrs. Ivery & Sons, Dorking; Mr. Wheeler, gardener to S. F. Goldsmid, Bart., Regent's Park; Mr. James, gardener to W. F. Watson, Esq.; and Mr. Ratty, gardener to R. Thornton, Esq. In Mr. Turner's collection were well-flowered plants of Duc de Nassau, Apollo, and Ferdinand Kegeljan. The plants shown by Mr. James were small, but well-flowered; the best were Iveryana, Criterion, and Eulalie. Messrs. Ivery's collection contained good plants of Stella, La superba, and Duchess Adelaide de Nassau. Miscellaneous groups of stove and greenhouse plants came from Mr. Wheeler, who also contributed a collection of Cape Heaths; amongst the latter were well-flowered specimens of Erica Victoria, E. persoluta alba, E. depressa, and E. Spenceri. Mr. B. S. Williams also showed a small group of Palms, Ferns, Crotons, and Cycads. In a choice collection of Orchids from Mr. F. A. Philbrick, Avenue Road, Regent's Park, were well-flowered specimens of Dendrobium nobile and cornuolens, Cattleya citrina, and Odontoglossum Pescatorei. Of three collections of Cinerarias the best came from Mr. James, Isleworth, who had remarkably evenly-grown plants, amongst which the best were Her Majesty, a fine purple-flowered kind, with a white centre; Attraction, rich rosy purple; and a good blue-flowered kind named Purple Gem. The same exhibitor also staged cut blooms of Cinerarias and a fine group of Cyclamens in excellent condition. Collections of hardy herbaceous plants in pots were shown by Mr. Roberts, gardener to W. J. Terry, Esq., Peterborough House, Fulham. Amongst them were Scilla campanulata and rosea, Trillium grandiflorum, Primula cortusoides, Anubria purpurea, and Dielytra spectabilis, all in good condition. Of Amaryllids two collections were shown. Messrs. Veitch & Sons contributed a collection of new plants, amongst which were two new Crotons, viz., C. McArthurianum and C. variable; Caladium Fairy Queen, a silvery-leaved kind with bright green edges; Coleus multiflorus; Gloxinia, Mr. Gladstone, Lord Derby, Duchess of Edinburgh, and Sir John Lubbock; all excellent kinds well worth culture. Mr. B. S. Williams showed a new Croton named Prince of Wales, a graceful-habited kind with orange-spotted leaves having reddish veins. Mr. Roberts exhibited a new *Hæmanthus* named Terry, the flowers of which are bright scarlet with yellow-tipped anthers. Mr. J. Ivery showed a plant of *Pteris serrulata cristata gracilis*, a variety with graceful, drooping, crested-tipped fronds. Mr. Turner, of Slough, showed a dozen *Auriculas* in pots; the best amongst them were Charles Perry, a large, purplish-blue flower with a clear white centre, and Munstrel, a dark velvety flower with a yellow centre. Mr. Ford, gardener to J. G. Megaw, Esq., Upper Norwood, contributed two finely-flowered specimens of *Clerodendron Balfourianum*.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE PETIT TRIANON IN SPRING.

It is like the escape from a desert into a flowery land, leaving the repressed and tortured and starved trees, and many inanities of the large gardens at Versailles, and entering those of the gardens of the Petit Trianon. The trees are no longer paralysed, mutilated, or starved, but healthy giants; they inspire one with awe and admiration, while those we have just left give rise to pity and annoyance. The Pines of Europe attain great size and dignity, and so do the leafless trees. In April, when the tall Cherry trees are seen here and there among evergreen and Ivy-clad old trees, the effect is beautiful. The charm, however, of the Petit Trianon exists all the year round, though there are few sweeter times than the present, when the tender leaflets are swarming out into the warm air, and many trees are tasseled with catkins. The Grass is long, green, and pleasant, and, happily, walking on it is not "forbidden," like so many things in France. Housemaid gardening has not quite deprived it of Cowslips and Ladies' Smocks, which abound in the Grass. When shall we cease to mow and mutilate the sweet flowers that love to grow in the Grass? Mowing machines and razors are needful things, but one may have too much of them. I have just been reading in the "Débats" that M. Thiers shaves himself every morning with unerring firmness of hand at eighty. It is sad to think of the time and energy and soap the great man must have wasted in this exercise. Sadder still is it to think of the eternal shaving of lawns and slopes with the mowing machine; many of these might be bright with lovely flowers in early spring. Natives of our own and other countries would be most happy in the Grass, which might be cut once or twice a year without injuring their foliage; as we have seen so many give up or modify the desperate use of the razor, so no doubt we shall some day see a wisely modified use of the mowing machine and the scythe. There are thousands of primly shaved acres in pleasure-grounds from which flowers might be gathered and Grass cut that are now shaved close every fortnight. A carpet is pleasant to the feet, but we do not want carpets everywhere. Pictures, for example, are better still, and these in gardens may be on the Grass. Here it is pleasant to see many groups gathering Cowslips and Daisies in the Grass; there are no sentinels to prevent this, and one is pleased to see liberty so far realized as to permit of the gathering of Cowslips in the public gardens of France. But though France has no soldiers to guard the Trianon Cowslips, there is one at the gate, and a melancholy heap of Cowslips and Daisies tells how he has made all the happy people part with their treasures.

A fine effect is to be seen just now in the gardener's garden at the Trianon: it is afforded by a number of fine old specimens of the early Magnolias in the full majesty of their blossoming. They sometimes stand up boldly out of clumps of American plants and the like. The contrast between two such dissimilar types of vegetation tells well; the flowering trees are seen to advantage, and the pudding-like masses relieved. A noble specimen of the pyramidal Oak is fine here even in its wintry dress. This gardener's garden is most interesting and varied, and is charming in summer and autumn; I have never seen a king's garden so pretty. At one end there is a huge Orangery quite covered with a Wistaria, which will soon be a vast curtain of graceful bloom. V.

THE SCHOOL OF HORTICULTURE AT VERSAILLES.—The old *potagerie* is being gradually changed into what promises to be a good school for gardening. As we write many of the wall trees and tall espaliers are in bloom. A more beautiful sight has rarely gladdened the eyes of fruit growers. Some of the walls are furnished from top to bottom with trees, and many espaliers are models of beauty and health. In other parts of the garden remains of a less desirable state of things are to be seen, but on the whole there is much reason to be gratified with the present condition of the garden.

NOTES OF THE WEEK.

NANTHOCERAS SORBIIFOLIA.—This new shrub figured in THE GARDEN (Vol. VIII., p. 521) is now blooming vigorously in the Paris Garden of Plants. We have never noticed so much bloom on the branchlets of any other shrub. In England this shrub will form a valuable addition to those blooming about the 1st of May.

THE ASH-LEAVED MAPLE IN SPRING.—I know nothing among the varied aspects of spring even in gardens more beautiful than old specimens of this tree in spring, when it is curtained with its slender, tapering tassels of flowers. It is scarcely necessary to add that this is the green form of the now well-known variegated Maple. I have lately seen a good many old specimens in flower, and they are the most striking trees in the grove at present.—V.

BRUNFELSIA AT KEW.—Numbers of these free-flowering stove plants are now remarkably showy in the Palm-house at Kew. They are arranged at intervals along the side stages, and each bears from sixty to seventy large purple or white-scented, salver-shaped blossoms. Associated, as they are here, with other flowering and ornamental-leaved plants, small Orange trees, &c., they have a fine effect.—C. M.

AKEBIA QUINATA IN APRIL.—Of all my botanical curiosities, so to say, this proves the most interesting. I have it trained over an arch in the garden wall, and just now half hidden among its delicate, twining shoots and elegant leaves there are numbers of quaint but beautiful chocolate-purple flowers. The young shoots have a similar hue, and are springing out in the most charming manner.—V.

A NEW *PHALANOPSIS*.—A very distinct new species of *Phalanopsis* (*P. fasciata*) is now flowering in Mr. Bull's nursery at Chelsea. It has thick leathery leaves, and bears its flowers on a spike 5 in. or 6 in. in length. Each individual bloom is about 1 in. in diameter, the sepals and petals being of a pale yellow or honey colour blotched and streaked with brown. The lip has two erect, fleshy, lateral lobes at its base, the central lobe being oval in form with thickened margins, and having a smooth ridge down the centre. Without being showy, it is an interesting little plant, especially just now when new species of *Phalanopsis* are so rare.—B.

TETRATHECA ERICOIDES HIRSUTA.—Several plants of this little hard-wood greenhouse shrub are now finely in flower in Messrs. Rollisson's nursery, Tooting; its deep rosy-purple blossoms are produced in great abundance even on small plants, and they are much more effective than those of the species. Plants of this *Tetratheca* may be grown with comparative ease, all they require being good sandy peat, a light, airy situation, and abundance of water when in active growth.—S.

ABUTILON VEXILLARIUM.—This *Abutilon* forms a striking object in spring on the roof of a greenhouse or conservatory. A large plant of it used in this way in a house at Kew is now bearing a profusion of drooping tubular blossoms, which, being of a showy red colour, tipped with orange, and associated with abundance of finely variegated foliage, are very effective, a condition in which this plant will probably remain during the greater part of the summer.—J. C.

GESNERA HENDERSONI.—This new *Gesnera* is now blooming freely in the Pine-apple nursery. Its leaves are deep green and the flowers brilliant scarlet—colours which contrast well with each other. To early-blooming plants this will be found to be a useful addition, inasmuch as it continues in blossom in a cool house for several weeks together in spring, when bright-coloured flowers are in greatest demand.—C. S.

PASSIFLORA QUADRANGULARIS VARIEGATA.—Most people are acquainted with the green-leaved form of this beautiful free-flowering stove or rather warm greenhouse climber, but the variegated variety of it is seldom met with. Trained up the roof of the Palm-house at Kew may now, however, be seen a large plant of it with leaves profusely blotched with golden-yellow; therefore, even when not in flower, this variety produces a good effect. It is not so luxuriant as the ordinary *Grauvilla*, and therefore better suited for houses the roof-room of which is limited.—J. K.

GOLDEN ONCIDIUMS.—*Oncidium*s are apt to weary even the most earnest lover of flowers by their sameness of yellow and brown; happily, however, all *Oncidium*s are not so depressing in this respect, and three of the most beautiful, namely *O. varicosum*, *O. Marshallianum*, and *O. concolor*, are just now flowering in Messrs. Veitch's nursery at Chelsea. *O. varicosum* is neat in habit, having speckled, two-leaved bulbs, and bearing gracefully-drooping panicles of pure golden flowers, 1½ in. to 2 in. in diameter, each individual flower being as pure in colour, and as perfect in form, as the most exact florist could desire; *O. Marshallianum* is scarcely so perfect in form, but it is a distinct in colour, and is one of the most showy of all the species;

O. concolor is dwarf in habit, bearing short drooping spikes of soft yellow flowers, which remind one of those of *Burlingtonia fragrans* in size and form. Apart from their purity of colouring, the above species are especially desirable, since all possess the habit of blooming profusely in a small state. They do not absolutely require an Orchid-house in which to grow them, but may be successfully cultivated in a warm plant stove along with Ferns and fine-foliaged plants, and they deserve a place wherever choice and distinct tropical flowers are appreciated.—B.

PANCRATIUM SPECIOSUM.—A specimen of this Amaryllid is now very attractive in the Palm-house at Kew. It bears several flower-spikes, each of which is surmounted by a large umbel of pure white funnel-shaped flowers.—S.

PHOTINIA SERRULATA IN FLOWER IN OXFORDSHIRE.—I have never heard of or seen this plant flowering elsewhere in Britain. It began showing flower-shoots here last autumn, and they have been gradually increasing ever since, but I fear this last frost has injured them so much that the blossoms will not open, and I even find that they are dropping off. The plant is on a south wall, and measures 1 ft. one way and as much the other.—A. MACFARLANE, *Great Yew, Enstone.*

DENDROBIUM DENSIFOLIUM.—A specimen of this showy Orchid at Kew has lately borne some twenty large drooping clusters of flowers. An some of the spikes could be counted nearly forty beautiful golden blossoms. In Mr. Day's collection a plant of this *Dendrobie* is reported to have produced nearly 100 clusters of bloom at one time.—W.

WEST INDIAN PINE-APPLES.—A consignment of these has thus early arrived in Covent Garden Market, where they are now selling at from 1s. to 1s. 6d. each. It need scarcely be added that in quality they are much inferior to the Pines that come from the Azores, but, being cheap, are useful for preserving or for candying.—B.

ODONTOGLOSSUM ROEZLI ALBUM.—Several plants of this lovely *Odontoglossum* are now flowering freely in Messrs. Veitch's nursery, Chelsea; their blooms, too, individually are unusually large, some of them measuring from 4½ in. to 5 in. in diameter. They are of the purest white colour, and, on that account, very useful in bouquets and other floral devices. When more plentiful this will doubtless prove to be one of the most serviceable *Odontoglossums* in cultivation.—C.

IMPORTED VEGETABLES.—Large quantities of Green Peas are now being received in Covent Garden from the warm and sheltered parts of France, and also from Algeria, whence they are consigned by way of Paris; and during the past week we have noted gangs of Pea-shellers almost as busily engaged in that work as in the summertime, when English-grown Peas are abundant. It is, too, a noticeable fact that the French Peas are far superior to those that come from the warmer climate of Algeria. The succulent Long White Turnip of the Paris market gardens, together with salad vegetables, is also now being sold by auction daily in large quantities. French and Channel Islands Asparagus is abundant, and comes packed in flat lath boxes 2 ft. wide, 15 in. deep, and about 3 ft. in length. A few Globe Artichokes and Cardoons come from Marseilles, and now and then a batch of fresh, though as yet pale-coloured, Tomatoes.—B.

THE FLAMINGO-PLANT.—The scarlet-spathed *Anthurium Scherzerianum* is now so well known in all good gardens that it would appear almost superfluous to make further allusion to its already acknowledged good qualities. In the Royal Exotic nursery, Chelsea, however, we have just seen a line of large specimens—say twenty or thirty plants at least—occupying the front bench of a house devoted to tender Arancarias, Palms, Aralias, and other dark green-leaved plants, and the effect so produced is one of the most distinct and striking we have ever seen. It is one of those imperial plants which does not kindly brook a rival, and never looks better than when seen in association with bright and varying greenery. This is shown by the tawdry appearance of floral decorations in which its spathes are introduced, and if any other flower be associated with it for effect it must be its relative, the white Arum Lily.

NATIONAL AURICULA SHOW.—The exhibition of Auriculas held at the Crystal Palace on the 24th inst. was in every way, thanks to the exertions of the honorary secretary, a most successful one, about 1000 plants being exhibited, and the majority of them in really excellent condition. The Auricula is, we believe, the only true Alpine plant which has hitherto become popular as a florist's flower, its culture dating from 1582, the year in which Clusius introduced *Primula auricula* and the natural hybrid *P. pubescens* from the Tyrolese Alps into Belgium, from whence it must soon afterwards have been introduced to old English gardens, inasmuch as several varieties are figured and described by Parkinson in 1629. Professor Kerner, of Innsbrück, who has made a special study of the Alpine

Primroses, names *P. pubescens* as being the original parent of the cultivated *Auricula*, *P. auricula* proper being the parent of the "Alpine" race. Auriculas of all kinds are so rich and variable in colour, and may be so successfully grown in the smallest garden, that their culture is to be recommended, and the exhibition, to which we allude more fully elsewhere, has done good work in bringing so charming and variable a flower into more prominent notice.—B.

Larvæ of Daddy Long-legs.—This destructive little pest is unusually abundant this spring. I found no fewer than eight yesterday morning at the root of my only plant of *Wulfenia Amhersti*, which it is needless to say they had destroyed. They remain close to the collar of the plant just beneath the soil, and goaw off the leaves and shoots at night. I found several *Calochorti* planted out in a pit gnawed off in this way yesterday, and thought at first it was the work of a slug, but on turning up the soil with my finger the culprits were at once discovered and instantly killed. I do not think they often touch the bulb or root of the plant itself, but they graze off every leaf and blade and shoot as clean as if eaten by a sheep.—H. HARPUR CREWE.

Leaves for Garnishing Fruit.—Some kinds of leaves are more suitable than others for this purpose. Strawberries, for instance, look best associated with their own foliage; Grapes may be laid on their own leaves, but there are others which suit them quite as well. One of the best plants for furnishing leaves for garnishing all kinds of fruit is the Curled Mallow, an annual of which I make three sowings in the year in rich soil—the first early in April, the second about the beginning of May, and the third about the same time in June. The leaves are about the size of small Vine leaves, and beautifully frilled. Wherever fruit has to be garnished, this plant should always be grown. The Ice-plant also furnishes good leaves for summer garnishing, its glistening, icy appearance having a cool and pretty effect on the table. It should be sown in a pan or box, in heat, in the first or second week in April, and planted out in the open border in May. These are the only plants which I grow for garnishing fruit in summer and autumn. In winter and until this time variegated Kale and Bay leaves answer the purpose. Bay leaves are rather stiff for Grapes, but for Oranges, Apples, &c., they may always be used with good effect.—A NORTHERN GARDENER.

Senecio saracenicus.—I should not recommend any one to grow this plant in a garden; it is no doubt very handsome when in bloom, but next to *Symphytum caucasicum*, which is equally pretty, it is about the worst weed that can be cultivated. It increases with almost miraculous rapidity, and simply chokes out everything else. It is easily naturalized on the banks of streams and ponds, where it forms a very handsome object, and any one who will take the trouble to introduce it into his local flora will be conferring a benefit upon the neighborhood. Can any one furnish me with a small plant of *Senecio paludosus* and *Cineraria palustris*, two very handsome plants, once fairly common in the Fen districts, but now, alas! in consequence of drainage and cultivation almost extinct? I am very anxious to try and introduce them into some swampy ground bordering on the large reservoirs in this neighbourhood. I shall also feel greatly obliged to any one in whose neighbourhood *Orchis militaris* grows, if he will send me a couple of tubers, as I wish to grow it in my garden.—H. HARPUR CREWE, *The Rectory, Drayton-Beauchamp, Tring.*

Seedling Daisies.—Until this spring I had no idea that so many pretty plants could be obtained from a packet of double Daisy seed. True, nearly the whole of the seedlings are white, and a proportion are only semi-double, or showing the eye so clearly as to render them valueless. But some are exquisite in form, and if not so large as might be expected, yet they are as double as could be desired. One or two pure white kinds promise to make good bedding varieties, as the flowers are produced on stiff foot-stalks and in great profusion. One selection I have named Snowball, the flowers being very white and exactly resembling miniature *Pompone Chrysanthemums*. Some of the plants produce pretty rose and pink tipped flowers, and will make lovely masses. In all I have been enabled to make up a collection of twenty distinct sorts.—A. D.

Spring Flowers for Vases.—*Helleborus fœtidus*, with its light green, drooping flowers, which remain fresh in water much longer than those of most plants, looks well in vases mixed with Holly berries, or early spring flowers. The very dark green leaves of this *Hellebore* contrast well with its flowers, the disagreeable smell belonging to which goes off when placed in water. *Ornithogalum nutans* in blossom this month also looks well in vases; it has a peculiarly soft, silvery tint, and the white inside the flower being half transparent, the green stripes outside partly show through it. It blossoms well, and for a long time, when put in water, and has a fine effect when mixed with pan or Apeunne Anemones.—O.

THE FLOWER GARDEN.

LILY INSECTS.

(CRIOCERIS MERDIGERA).

CULTIVATORS on the Continent are familiar with a little insect of a vermilion red colour, which is found in summer upon the different species of Lily and allied plants, such as the Crown Imperial. It is found in England, too, especially in the London district, upon the common white Lily; but here it is so few in number that it is more likely to be sought for on account of its beauty than for its destruction as an injurious insect. It is a Crioceris, which has been named by entomologists *Crioceris merdigera*, and it feeds on the leaves of the Lily. The female lays her eggs under the leaves in little heaps of from five to six. The young larvæ leave the eggs at the end of a fortnight; as soon as they begin to walk they place themselves side by side, and eat resolutely onwards. After the first casting of skin, they disperse in different directions over the leaves, above as well as underneath; then they attack them sometimes at the ends, sometimes at the sides, often even they pierce them through the centre, and when the leaves fall they throw themselves upon the stalks. These larvæ are lazy, and give themselves little movement, only changing their places when a leaf is half devoured.

The larvæ by the end of a fortnight attain their full growth; then they enter the earth to metamorphose themselves into nymphs. The perfect insect is hatched a fortnight later; those which transform themselves into nymphs in the autumn pass the winter underground until the beginning of spring. It is not difficult to keep the ravages of this species within bounds. The little heaps of greenish dirt under which the larvæ live are sufficiently conspic-

uous and the larvæ are easily removed by hand-picking—so is the perfect insect; so that really there is no excuse for any one having his plants disfigured by them. A. M.

Crioceris merdigera on the common White Lily.

LILY BULBS.

"F. W. B." says, alluding to his sketch of my Lily "seed-bud" (see p. 268):—"It will be seen at a glance that it (the seed-bud) is nothing more than one of the axillary buds which exist at the base of each scale in nearly all Lily bulbs." Now, may I ask if he will undertake to cut up three bulbs, and, before he cuts them, describe, as I did, where and at what point he would be sure to find, in all the three bulbs, the axillary buds to which he alludes? Or can he prove that a bud, of any description whatever—no larger than a canary seed in January—will grow up to a full-sized bulb and bloom freely the next year? I think I may venture to say he cannot. And yet the legitimate seed-bud, which is every year found in its own place, will do all this, and more; for if the culture happen to have been liberal, it will often grow a much larger bulb, and flower much more luxuriantly, than the parent bulb did the year before! Now as to *Lilium candidum* being an evergreen. At page 268, "F. W. B." says:—"Danedin again asserts that *Lilium candidum* is no more an evergreen than any other species, whereas the reverse of this is a well-known fact to every Lily grower, seeing that the plant bears green leaves nearly all the year." "F. W. B." is wrong in saying, "it is a well-known fact to every Lily grower"; because some Lily growers know as well as I do that *L. candidum* is not an evergreen. Be this as it may, however, let us put aside mere assertions and see what experiment and examination can do for us. Every Lily

cultivator may be said to be acquainted with the external appearance of the bulb of *L. candidum*; but there are few comparatively who are well acquainted with the economy of its interior. When lifted in autumn, the outer scales of the parent bulb are found to be tier upon tier of an imbricated lanceolate character, the outer or lower tier of scales lapping somewhat more than half-way over the next tier, and so on until the upper tier is reached. But we have now to speak more particularly of the inside. If a plump bulb that has bloomed be taken up as soon as the leaves at the points begin to decay (not later) and cut in two vertically, that is, right down through the vertex and axis of the bulb, we shall have presented to our view a section of the new bulb (within the old one), which is, or was, destined to flower during the next season. At this early period the scales of the new bulb will be seen to be placed the one tier over the other, but in a manner the very reverse of those of the parent bulb; that is to say, the innermost scales, next the axis, will be seen to be the shortest, the next tier completely overlapping them, and so on tier upon tier, the outer scales reaching from a somewhat solid fleshy base to the top, where they meet, leaving a very slight orifice at the apex. These scales, numbering from five to eight on each side of the axis, counted on the sectional face, enclose in their centre the undeveloped flower-stem, which, with the aid of a magnifying glass, will be seen to be richly covered with very minute leaves. These leaves grow up and push themselves aboveground before the winter commences and a considerable time before the main stem itself appears. If the halves of the bulb be placed on a table in a dry room where they can have

the benefit of the sun, the drying system will in a few days cause the soft, pulpy parts to dry and contract, and so make the fibrous parts of the minute leaves to stand out in such relief as to be noticeable by the naked eye. These leaves, which have led to the mistaken idea that this Lily is evergreen, are simply the barbingers or precursors of the flower-stem itself, and are annually generated in the very infancy of the new bulb, and are peculiar, as far as I can learn, to this Lily alone. This is clearly demonstrated if we lift bulbs of *Lilium croceum* and *L. bulbiferum* and dissect them in the same manner. I mention these Lilies for this reason—that they are cheap and can be replaced at very little expense. *L. bulbiferum* and *L. croceum* agree very nearly with one another, but they differ from *L. candidum* in this singular peculiarity, namely, that merely scales are found on their rather long axes, and no leaves as in *L. candidum*. The same difference is observable in *L. auratum*, *L. speciosum*, and other Lily bulbs. We now come to the second part of this experiment, which is of no less importance than the first. From the time the first bulb of *L. candidum* has been taken up and cut in two, as directed, until the bulbs of the same species are seen to be pushing their leaves above the ground, another plump bulb of *L. candidum* must be taken up every week or ten days, and cut in two in the same manner, in order to observe the progress the new bulb and its leaves are making. It should here be impressed on the mind of the experimenter, that if the bulb taken up has not flowered during the past season, the experiment will be a failure. When examining the bulb for the purpose of marking the progress which the new bulbs and its leaves are making, do not overlook the process of decay which the old or parent bulb is undergoing. This is all-important, in order to decide the question at issue. While the new bulb is growing, the contents of the parent bulb are being gradually absorbed by the new bulb, and as the remains of the old bulb are no longer requisite when the former has attained its full growth, all that remains of the parent bulb dies off completely. If this be carefully observed, and the parts constituting the new bulb, and those belonging to the old bulb, be marked off distinctly, it will be seen to be proved, beyond a doubt, that all vitality in the old bulb has ceased to operate, and that it is a new and distinct bulb, which every year pushes up the leaves above the ground before the

ferum and dissect them in the same manner. I mention these Lilies for this reason—that they are cheap and can be replaced at very little expense. *L. bulbiferum* and *L. croceum* agree very nearly with one another, but they differ from *L. candidum* in this singular peculiarity, namely, that merely scales are found on their rather long axes, and no leaves as in *L. candidum*. The same difference is observable in *L. auratum*, *L. speciosum*, and other Lily bulbs. We now come to the second part of this experiment, which is of no less importance than the first. From the time the first bulb of *L. candidum* has been taken up and cut in two, as directed, until the bulbs of the same species are seen to be pushing their leaves above the ground, another plump bulb of *L. candidum* must be taken up every week or ten days, and cut in two in the same manner, in order to observe the progress the new bulb and its leaves are making. It should here be impressed on the mind of the experimenter, that if the bulb taken up has not flowered during the past season, the experiment will be a failure. When examining the bulb for the purpose of marking the progress which the new bulbs and its leaves are making, do not overlook the process of decay which the old or parent bulb is undergoing. This is all-important, in order to decide the question at issue. While the new bulb is growing, the contents of the parent bulb are being gradually absorbed by the new bulb, and as the remains of the old bulb are no longer requisite when the former has attained its full growth, all that remains of the parent bulb dies off completely. If this be carefully observed, and the parts constituting the new bulb, and those belonging to the old bulb, be marked off distinctly, it will be seen to be proved, beyond a doubt, that all vitality in the old bulb has ceased to operate, and that it is a new and distinct bulb, which every year pushes up the leaves above the ground before the

winter sets in. The author of "Notes on Lilies" says:—"It is impossible either to deny or accept 'Dunedin's' statements as facts." This being so, may I ask him to favour me so far as to give these remarks his best consideration, as I feel sure his object must be the same as mine, viz., the advancement of Lily culture. DUNEDIN.

ALPINE FLOWERS AT YORK.

NOTWITHSTANDING the inclemency of the weather, the Alpine flowers on the rockwork at York are really beautiful. *Primula pulcherrima*, which is growing freely, is producing large globose heads of lilac-purple flowers, and the individual blossoms are so closely packed together that it would be almost impossible to thrust in even a pin's point without touching the flowers. *Primula marginata* is just putting forth its lovely bluish-lilac flowers. Then there are the Anemones: *A. blanda* is just over, but the white and blue flowers of *A. apennina* are in full beauty. Associated with the latter on a shelving bank exposed to the south are *Omphalodes verna*, common wild Primrose, wild Wood Anemone (*A. nemorosa*), and self-sown patches of *Myosotis dissitiflora*, altogether forming a beautiful and lovely combination. *Anemone fulgens*, on another part of the rock-garden, is very brilliant. I also noticed several varieties of *A. hortensis*. *Primula spectabilis*, with its deep green, entire leaves and trusses, composed of large, deep violet-purple flowers, borne on slender, brownish-purple stems from 2 in. to 4 in. high, is likewise strikingly pretty. The little Ranunculoid-like Anemone (*A. ranunculoides*) is a pretty and desirable plant, for although the flowers are not quite so large as those of the wild Wood Anemone, yet they represent a colour among Anemones with which we cannot afford to dispense, the flowers being bright yellow. It appears to thrive best when planted in damp peaty earth slightly shaded from the mid-day sun. *Aubrietia græca superba*, almost smothered with flowers, hangs in sheets from the crevices of the rocks. This is a decided improvement on the old *Aubrietia græca*, the colour of the flowers being so much deeper. *Tulipa Greigi* is a fine early-blooming plant, and one which has proved to be quite hardy. I ought not to omit *Anemone vernalis*, a beautiful little Alpine plant now in flower; it produces lovely, delicate, silky buds and pure white blossoms, borne on shaggy stems not more than from 4 in. to 6 in. high: its leaves are deep, shining green in colour, and they remain on the plant throughout the year. *Cardamine trifolia*, with its snow-white flowers and deep green leaves, is also a pretty object in shady nooks on rockwork at this season of the year. I noticed several roots of *Lilium giganteum* pushing upwards with no small amount of vigour. They are planted in an artificial bog, in which the American Blood-root (*Sanguinaria canadensis*) appears also to be quite at home, and to flower freely. The same may be said of *Primula cortusoides amœna*. A short distance from the rock garden I noticed in flower *Trillium atro-purpureum*, a plant which I believe is as yet rare; and there was one little gem which I must not overlook—it was *Soldanella minima*, flowering in a small pot, its delicate little solitary blossoms resembling miniature bells; its pretty little leaves, too, are worthy of notice, so small and yet withal so green and rigid.

R. P.

THE CARNATION AND PINK.

THESE have been cultivated as garden flowers from very early times. In rich or in wet soil, both the Carnation and Pink are short-lived; but in dry situations—as, for example, on a rockery—they will grow and flower profusely for a length of time. As regards propagation, layering is the plan usually adopted, and operations for the purpose begin about the beginning of August, or a couple of weeks earlier in cold localities. About that season the plants have ceased flowering and made their growth, and the layer sown made of the young shoots. The first and preliminary step is to prepare a compost, which should consist of clear river sand mixed with its hulk of leaf-mould and loam together. This should be spread round and under the branches of the plants to be layered about 4 in. thick, and the layers must be pegged down into it, and covered about an inch deep. In layering the shoots the leaves are removed up to about the third or fourth joint, and the knife is inserted from the fifth joint, and run up to the next one, cutting the shoots about half through. This forms a tongue on the cut side, which must be covered a little below the joint to which the incision has been carried, and the shoot should then be bent so as to make the cut gape, and in that position pegged securely into the compost. A layered Carnation shoot may be described as a cutting half removed from the parent plant; the slitting up to a joint is made with a view to facilitate the rooting process without depriving the cutting of the support of the parent

stem in the mean time. In this way the shoots of the plant are layered all round, and the hillock formed by the compost is afterwards packed between the shoots with smooth, round stones, each about 3 lb. or 4 lb. in weight, in order to keep the birds from scraping the compost away, which they are sure to do if they can reach it, in hunting for worms, &c.; water-worn stones from the bed of a river are best for the purpose. In a month or five weeks after layering, if the plants have been watered regularly during dry weather, they will be rooted, and they should then be lifted and potted, and planted out in the borders where they are to remain. In most gardens where the stock is propagated annually in this way, the plants are potted in 6-in. pots, and wintered in cold frames, the pots being plunged in ashes to protect them from frost; and in spring they are planted out, the old plants being thrown away. Whether potted or planted out in beds after rooting, the best staple for the Carnation and Pink is a good loam, free from wireworms, and it may be mixed with leaf-mould and sand; but they will thrive in common garden soil well enough. When wintered in frames, it is necessary to give the plants plenty of air on all favourable occasions, as the Carnation does not thrive in a close atmosphere. Anything like fire-heat must of course be avoided; and if the frost should be severe, mats or straw should be used for protection. During the summer the plants should be watered in droughty weather, and they must be guarded against rabbits and field mice, which are fond of them; but these vermin are most destructive during winter. When the flower-stems grow, they should be supported singly with small neat stakes, or two or three stakes may be put round each clump, and the matting run round the whole at once, to keep them from falling upon the ground. Some cultivators go to great trouble in disbudding, trimming, and otherwise manipulating the flowers; but here it is only discussed to give the reader an idea of how to grow the Carnation as a border flower, and it is not needful to refer to such practices. J. S.

TULIPS DURING WET AND WIND.

NOTWITHSTANDING the promising appearance of Tulip beds generally, cultivators of these flowers are having an anxious time of it. Heavy showers and the almost constant covering of the beds necessary to prevent them from being saturated with water, cannot fail to be prejudicial to the well-being of the plants. Some beds are already beginning to present a deteriorated appearance; the foliage is becoming pale green, and the stems of the plants drawn, owing to the absence of the strengthening influence of the sun's rays. In covering a Tulip bed the main framework should be a fixture, but the canvas covering should be removable at will. During the winter and early spring months, semi-circular iron hoops, placed on the beds and covered with mats, are employed to ward off frost and heavy rains; but when the plants begin to grow vigorously, a stage is requisite, in order to afford airiness and space, and at the same time suitable protection to the plants. The canvas ends of the stage may remain closed, but the walls or screen, or rather sides, should be fastened to a roller at the bottom, which, by means of a pulley, can be rolled up to the ridge or lowered, as may be desired. By this means air and light can be given to the bed on either side, or both, when it is requisite to do so. Directly a shower of rain or hail threatens, the top should be lowered, and it will be advisable to do this every night when the plants approach blooming; the side cloths should be of very thin canvas—cheese cloth is recommended by some, as it keeps off the sun, and at the same time permits a free circulation of air. As soon as the blooms show colour, direct sunshine should be excluded, but the plants may have all the air possible. Rough winds, whether from the east or west, must be guarded against, a recommendation which specially applies to those who grow a few Tulips in the open air without protection of any kind. When looking over such a bed a few days ago, immediately following the occurrence of blustering east winds, there could be seen several plants having only one leaf, in all probability all that would be made this season—and some of these were nearly snapped off. The loss of this leaf will prevent the bulb from blooming next year, while, if it can mature it, it will be so helped thereby as to be strong enough to flower the following season. It is therefore well to give such plants the support of a stake, tying the leaf securely to it; the labour is by no means wasted, and perchance a fine bloom will repay the operator a year hence for his timely care of the plant at a critical moment. D.

Double Blue Hepatica.—I have found no difficulty in the culture of this, although I had some difficulty in obtaining it at first. A somewhat shady position, with a good admixture of peat in the soil, suits it admirably. There is the greatest difference in all Hepaticas, according to the culture which they receive. They should

be grown in shady, sheltered spots, where the foliage will be preserved evergreen to protect the flowers and young leaves when they push up. I was first made aware of this by some plants which I brought home from Lake Como, which, being carefully sheltered, put forth blooms nearly double the size, and of a more intense blue than those in the open border. The earliest to flower is the double red Hepatica, then come the blue, the white, the single pink, and last of all the double blue.—SALMONICERS.

Variiegated Japanese Honeysuckle and its Uses.—This Honeysuckle when grown under certain circumstances is certainly one of the handsomest-leaved plants in cultivation. It does well on a wall or on a tree as is shown (see p. 322). Last summer I saw it used effectively in the winter garden at Southport in a basket from which its long shoots hung down gracefully: it does well also as a fringe for baskets on lawns, and I have likewise seen it used effectively as an edging for flower beds, a position in which it has to be often clipped, and I should add that it would show its variegated leaves to the best advantage in soil not over-rich. As regards coverings for trees, we have here a variegated Ivy upon an old Willow tree, the stem of which is quite covered with the Ivy, and it has a very ornamental appearance the whole year round.—R. M.

Hardy Caeti.—I agree with Miss Kingsley in the belief that Caeti are more hardy than is generally supposed. When in America I saw vast areas of the plains inhabited by them, which plains were covered with snow in November; colder still must their hill-homes be. I have also noticed species in cultivation thrive well, especially when the succulent "leaves" are protected from injury. When the foliage of a plant, or what answers to it, is perennial as in Caeti it is most important to so place it that it may be safe from various injuries, quite apart from those of climate. The best place for Caeti would, as a rule, be on well-drained ledges and fissures in the rock garden. I, however, have noticed the Opuntias quite at home on the level ground, but never so well as when they were protected by a wire cage from being trampled on or injured by tools, &c.—V.

Bedding Plants and Spring Flowers Intermixed.—Small beds of *Scilla sibirica* with borders 8 in. or 10 in. wide of *Narcissus* minor were very effective here last month. Some spring bulbs, and roots which die down in summer, such as those of Squills, Anemones, double Jonquills, and *Narcissus poeticus*, we only take up about every third year in order that the beds may be dug and the soil enriched. This is done as soon as the plants have gone out of blossom, and they are replanted at once. Summer bedding plants are put in without disturbing the spring flowers, and they do quite as well as those planted in empty beds. When they are taken up in the autumn, the beds are heavily top-dressed, especially those filled with Squills and Anemones. Thus treated, these spring flowers seem to do much better than if they were transplanted every year; none of the bulbs are lost. *Scilla sibirica* sows itself when left undisturbed. One bed of Anemones has *Verbena venosa* growing through it, and in summer a few plants of Mangles' *Pelargonium* planted through it makes "Beaton's shot-silk bed" without any further trouble.—NORTH WALES.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Iris Chamæiris.—This pretty little Iris, now in blossom, is valuable from its rich yet delicate yellow colour. It is only a few inches high, and blooms abundantly.—V.

Ranunculus millefoliatus.—This is a charming little Buttercup with finely divided leaves and large yellow flowers. It grows quite freely on the level ground, and is hardy. It likes a free sandy soil best.—J. H.

Delphinium nudicaule.—This is a true perennial with me, at least upon rockwork. A strong tuft of it is now pushing up for the fourth time in the same dry, sunny position. It is very apt to be lost in borders, as the young leaves are very like those of a Buttercup, and apt to be destroyed as weeds.—SALMONICERS.

Anemone fulgens and other Wind-flowers.—It is marvellous to find how long and how superbly *Anemone fulgens* continues to bloom, more than three months having passed since its first flowers expanded. Can as much be said of any other early spring flower? The pretty Double White is following close on the heels of *A. apeunina*, and the three make a delightful bed. These Anemones are not nearly so well known as they should be.—D.

Primula cortusoides amena alba.—Can any of your correspondents inform me how to properly treat this Primrose? Last year, for the sake of variety, I secured a dozen plants of it which were treated exactly the same as *P. cortusoides amena*, but from all of them I have only obtained one solitary spike of flowers and that a poor one, consisting of only three blooms, the colour of which was white with a green stripe down the centre of each petal. This failure is unaccountable, as all my plants of *P. c. amena* are in excellent condition, several of them in 6-in. pots bearing twelve spikes of blooms with an average of eight blooms on each spike, each as large as a half-crown. For several years I have experienced perfect success with *P. c. amena*, but have never grown the white variety before. Is it worth growing?—H. HARRIS.

THE FRUIT GARDEN.

INFLUENCE OF TIME OF PRUNING PEAR TREES ON SEASON OF BLOOMING.

I AGREE with Mr. Baines' remark (see p. 272) that it is to be regretted that such an important practical question as this should have been so little discussed. Possibly the somewhat unceremonious manner in which the views which I advanced on the subject have been challenged, may have deterred other cultivators from expressing their opinions on the subject. All the views advanced (see p. 151) have been considered as unworthy of credence, and it has been taken for granted that the time of pruning has really no perceptible influence on the time of blooming. I reiterate that it has; and my faith in the correctness of my deduction is based upon the careful observations and the experience of many years, aided by the old doctrine familiar to all cultivators, though recently formulated under the new name of the conservation or concentration of vital force. Now Mr. Baines' facts and cases, so far as they may be accepted, go to establish the potency of the time of pruning on the season of blooming. The general and concurrent testimony of nearly forty years points in the same direction, and a tolerably successful practice of over a quarter of a century in the culture of hardy fruits has been moulded and shaped in accordance with the fact of a close relation subsisting between periods of pruning and times of blooming. I have, therefore, a right to repudiate hasty assertions on insufficient grounds, and to state that if any mistakes have been made, my conclusions have been arrived at as the results of almost a lifetime devoted to the observation of facts, and interpreting as best I could their true significance and meaning.

The theory of the concentration of force repudiated by Mr. Baines in its relation to Apples and Pears, though fully admitted in relation to other trees and shrubs, also favours my views. Granting that some of the difference at least claimed by Mr. Baines between a Rose tree and a Pear exists, it must still be admitted that vital force is diffusive and divertible, as well as concentratable. Sap will, in fact does, flow in almost any direction and to any point where there is the freest outlet; consequently there is no insuperable physical difficulty in fluids passing from fruit-buds into wood-buds, or *vice versa*. If such a diversion of sap be possible—and few vegetable physiologists will be found to deny it—then the analogy between the effects of the late pruning of Roses or Peaches that bloom on the current year's wood is closely allied to the effects of early or late pruning on the fruit-buds of Pears, and Mr. Baines's arguments, based on the essentially different effects on the two, fall to the ground. Mr. Baines seems to forget that there are other attractors or expenders of sap besides the fruit-buds. Each wood-bud is engaged in the same or similar functions—for they may not be quite identical, though physiologists assure us that in the earlier stages the functions of fruit and wood buds are identical. Granting that they are similar, can it be contended that no difference is made to the season of growth—whether the buds or growing points of a tree be few or many? No doubt the numbers affect the time as well as the intensity, or force of growth. Even the positions of the growing points have an important bearing on the times of growth. In general terms, and, as a rule, the higher up upon the trunk, or branch, or twig, the earlier the bud opens. This alone explains most of the facts adduced by Mr. Baines, and shows them to have no necessary bearing on the point under dispute. The fact, for instance, of tall, unpruned orchard trees, flowering at the same time with more dwarf trees grown round the quarters of a kitchen garden and pruned closely every year before Christmas by no means proves that the time of pruning of the latter did not accelerate their bloom. I should say distinctly that it did, otherwise the two sets of trees would not have bloomed simultaneously, but the tall orchard trees would have bloomed a week or ten days in advance of the more dwarf and probably also more horizontal trees. The vertical direction, and even the additional height of the tall orchard trees, and their different character, account for all the facts given by Mr. Baines without leaving anything to the credit of his theory

that the season of pruning has no influence on the time of blooming. No fact can be clearer than that of the possibility of concentrating vital force by pruning. Full half the success of all our practice is based on the fact that by limiting the areas of vital force we augment its strength or intensify its energy. The vital force of trees is like that of horse power or drawing force of a steam engine. It is a given quantity. Divide it among a thousand, and each will have little more than a half of what they would have had had it been apportioned to five hundred. Admitting that the analogy is by no means an identity, inasmuch as each growing bud may to some extent create force as well as expend it, yet it holds good to show that by reducing the number of buds we concentrate vital force. It is so in a degree with buds, or else the whole system of dis-budding, as well as of pruning, is fallacious in theory and useless in practice. Mr. Baines, indeed, contends that the buds, and especially the fruit-buds, take the initiative in growth; his exact words are:—"The first efforts at growth occur in the fruit-buds themselves, and these are wholly influenced by the temperature of the air and the direct action of the sun's rays." In a preceding sentence he asserts that the roots are inactive, or rather passive, merely acting as channels, and making no extension until some progress is made in leaf development. Accept such a theory in its entirety, and all pruning must perforce be mischievous and a hindrance to growth. Each bud cut away is an active factor or modicum of force removed, and pruning becomes synonymous in its loss of power to the blowing off of steam from the locomotive. But this view of the origin of vital force cannot be sustained; on the contrary, roots are often abnormally active during what is called by a figure of speech the dead season; as a fact, there is no such season to any living plants. Even the leaves of Pear trees fall, not at the languid or sluggish bidding of death, but by the vigorous impulse of the new and growing life of the coming race of buds. These expand and fill up all through the winter, unless arrested by the forcible grip of cold, and the roots have a full share in their filling and furnishing. Instead, therefore, of speculating about which part the root or top starts first—it is much more true to assert that neither ever stops growing. The buds continue to become fuller of good things until they can no longer contain themselves, and consequently they burst into beauty. The roots never cease in their labours of collecting, conveying, and straying out for yet richer and further supplies. The resting of the roots is a figment of the imagination, of which a mere cursory examination at any season of the year, from January to December, would convince the most sceptical. Not only are the roots active, but the fluids are also in motion, and the motion of the fluids is in an upward direction, and though they may travel slowly, yet they will surely reach their destination—the buds—which any one may readily discern who examines the fruit or wood buds in November and March respectively, a period when the semi-dormant roots are supposed to have lain inactive. But, admitting that the powers of furnishing the buds and preparing for a start in the spring have been going on all the winter, it is surely obvious that if half or three-quarters of these buds had been pruned off in November, that so much the more sap would have been available for the remainder, which consequently would have been the sooner filled and started into growth. I do not affirm that all the vital force would have been directed to the remaining buds, but undoubtedly a sufficient amount of it to have exerted an influence on the time of blooming. No doubt the warm air and the sun have also a potential power in the matter, but other conditions being the same, the fewer buds, and the sooner the reduction was made in the autumn, the sooner they would be likely to open in the spring; for bud-growing is an affair of root filling and furnishing as well as of solar influences.

Mr. Baines' account of the two Pear trees that grew side by side, and flowered at the same time, after one had lost its head in a storm and the other had escaped unhurt, must have a passing notice. Here was a case of severe top-pruning in December; now let us see what happened and what difference this tremendous pruning made in the time of flowering. It made none—therefore the point is settled for all time. The Pear tree may be pruned when you will and it will flower all the same whether it is pruned or not. But I submit that

this case proves nothing but the vertical flow of the sap, which has already been adverted to. The wrecked tree, considering that only a few of the lower boughs were left, ought to have flowered several days or a week after the neighbouring tree that escaped. That it bloomed simultaneously with the uninjured tree proves that early and severe pruning did hasten its blooming, and, indeed, is a vivid illustration of the soundness of my views. The subsequent conduct of the tree, the larger size of the fruit, &c., all tend to establish the unmistakable truth of the theory of the concentration of force. Again, the simultaneity of the time of flowering in the two Pear trees, one of which was thickly studded with fruit-buds, and the other but sparsely furnished with the same, proves little to the point, inasmuch as the tree with few fruit-buds may have the more leaf-buds; and I contend that sap is divertible, and that, moreover, it will flow in any direction where there is an active outlet, no matter whether it is a fruit-bud or a leaf-bud. It is also a fact that the more fruit-buds the fewer leaf-buds, and *vice versa* as a rule; hence the mere difference of the numbers of fruit-buds may have little or no effect on the time of flowering, though on exactly the same principle thinning of such buds would probably accelerate it. What may be termed unnatural fertility may also have something to do with the precocious opening of the fruit-buds in trees studded with the same, for it must be remembered that fertility in excess is almost synonymous with weakness, and weakness is ever in haste—whereas strength mostly displays its power in a more leisurely manner.

D. T. FISHER.

— Although some make the date at which winter pruning is performed a point of great importance, I do not attach much value to such dates, simply because there is so little pruning required in trees that have been properly attended to as regards summer pinching and stopping, that the cutting away or retaining of so small a portion as it is generally found necessary to remove, can affect but little the hastening or retarding the growth in the entire tree. I am of opinion that the roots of deciduous trees are much more active when the leaves are falling than when the buds are bursting into leaf and flower.—J. GROOM, *Henham*.

When to Start Late Grapes.—This is an important matter, to which I am pleased to see attention directed (see p. 292); for nothing is worse than starting Vines at a wrong time. This not only leads to much extra anxiety, but also to extra expense. For instance, when the Vines have been very late in starting, the Grapes have to be ripened with fire-heat in autumn, and if this be imperfectly accomplished, then fire-heat has to be used nearly every day as long as the Grapes hang on the Vines, in order to keep them from rotting. On the other hand, when late Vines are started into growth early, it requires, as a rule, a great deal of fire-heat to prevent them from being checked in their growth until sun-heat is strong enough or the atmosphere warm enough, both day and night, to obviate all danger. Mr. Hinds recommends (see p. 184) starting late Vines "not later than the first week in February." This I consider nearly two months too early; Vines started then would be in their tenderest stage of development in March, and this, as a rule, is a most trying month for Vines in such a condition, and besides, the fire-heat that would be necessary to keep them growing from the end of January until the beginning of May would be a matter so expensive that few would care to incur it. "Chef" (see p. 292) comes nearer the mark when he recommends starting about the beginning of March; but even if left until two or three weeks after that, no bad results would occur. I have proved over and over again that both late and early Grapes may be thoroughly matured in six months after the Vines were started into growth. Vines started into growth the first week in April will ripen their fruit by the end of September, and this is quite as early as late Grapes are wanted in the generality of cases.—A NORTHERN GARDENER.

The Weather in North Notts.—An unprecedented rainfall of 22.03 in. has been registered here in six months, viz.:—October, 1876, 2.91 in.; November, 1876, 3.59 in.; December, 1876, 6.05 in.; January, 1877, 4.29 in.; February, 1877, 2.55 in.; March, 1877, 2.64 in.; total, 22.03 in. The rainfall in April is likewise much above the average, for up to this date (the 23rd) 2.65 in. have fallen. From the continued sodden state of the soil vegetation is very backward in this district, but there is now a prospect of a change for the better, as the wind has shifted from the north-east into the south, and the tem-

perature has risen considerably during the last few days. Gooseberry and Currant bushes are in full flower, and should frosts keep off there will be good crops, judging by the appearance of blossoms. Of late years crops of these fruits here have been injured by spring frosts two years out of three. Pears, Cherries, and Plums are likewise showing abundance of blossom-buds, which are now about opening, and should the fruit set well, heavy crops may be expected. Apples being late in flowering stand a still better chance of setting well, and they likewise promise to produce good crops. Apricots, Peaches, and Nectarines have plenty of fruit set here, but the trees on walls being protected with glass coverings are independent of the weather.—WILLIAM TILLERY, *Welbeck*.

Watering Strawberries.—Wherever Strawberries are forced, either in large or small quantities, April is generally a productive month, and much may be done towards increasing both size and flavour by a judicious use of the watering-pot. Drought and unhealthy root-action are sure precursors of red spider; but dryness at the root or in the atmosphere is not the sole cause of red spider—we have had one or two small batches of plants here this season which lost a large percentage of their roots through being saturated with applications of strong liquid manure, and I can safely say that such a crop of red spider I have never seen in all my experience as these plants produced, and yet I dare say the man who attended to these Strawberries had made up his mind that he would have both large fruit and clean foliage. Want of experience often leaves painful traces behind it. The strength of all liquids should be carefully tested on a few plants before all are subjected to their use. It is indispensable at all times and under all circumstances that the health and condition of the roots should be well understood by whoever uses the watering-pot. It may also be as well to observe (for the sake of the inexperienced) that a careful examination of the drainage will furnish some guide as to the strength at which the liquid should be applied; when perfect, the strength of the liquid may be increased with advantage, but where worms have interfered with a clear passage for water, considerable care should be taken in preparing and applying whatever liquid is used. What may be termed clogging soon reduces the power of the feeding roots to a minimum, and in the end impedes all chance of a clean healthy crop. We examine the bottoms of all pots before they are placed in the forcing houses, and we do what we can in all cases in which there is an appearance of the drainage being choked up. Flat-bottomed pots should not be employed in Strawberry culture; they do not allow the water to escape freely, and stagnant water (especially if it be liquid manure) soon rots the roots and induces ill-health: lifting the pots occasionally is as good a way of testing their condition as to drought as the more common one of tapping their sides, and it enables one to note whether the young feeders are peeping out from amongst the corks—a sign that the roots inside are in a healthy state. How people can recommend saucers, turf-trays, and similar appliances for Strawberry culture I cannot understand, unless the condition of the roots is not ascertained as often as it should be.—W. HINDS, *Otterspool*.

Variety in Oranges and Lemons.—A correspondent of the "English Mechanic" writes as follows on this subject:—"The firm with which I am connected uses a great many Oranges and Lemons. The kind of Orange employed is generally that called the Seville, a well-known sour or acid kind. Among them are frequently found what are called sweet Oranges; also among the Lemons some are found destitute of sourness, and even somewhat sweet. I had considered that these phenomena could be explained by the two kinds of each having been produced on different trees; but this year the Lemons have quite dispelled that idea—for we have found Lemons with some divisions of the fruit sweet, and some sour. The Lemons came this year from Messina. We meet with curious monstrosities at times. As one of them, I may instance that a small Lemon is sometimes found inside a large one. [Lindley and others agreed long ago that the Citron, Orange, Lemon, and Lime are all cultural descendants or sports of one botanical type or species, viz., *Citrus medica*, which was cultivated in the East thousands of years ere the Orange found its way to Southern Europe. The readiest way of accounting for the vagaries alluded to above is to assume that they are partial reversioners towards the different kinds from which they have descended.—ED.]

Beurre de Jonghe Pear.—This is comparatively a new Pear, a late one, and one of very great excellence. The Rev. G. Kemp first submitted examples of it to the Fruit Committee of the Royal Horticultural Society in 1875, when it was unanimously awarded a first-class certificate. It is a Pear that seems well suited to the climate of this country, which many of the Belgian Pears are not. The fruit is of medium size, of a true pyriform shape, very regular and even, tapering to the stalk, which is short and fleshy, inserted a little on one side, and always presenting the appearance of having been broken off. The eye is small and open, nearly level with the surface of the fruit. The flesh is greenish-yellow, very buttery and melting, with a fine rich flavour, and slightly perfumed. This fine Pear ripens during the month of January, and is equal in flavour to the best

of the earlier varieties. It is a valuable acquisition, and ought to be in every collection.—"Florist."

THE CALIFORNIAN ELDER.

(*SAMBUCUS CALIFORNICA*).

WHITE and Black fruited forms of the common Elder tree (*Sambucus nigra*) not unfrequently find places in outlying shrubberies and woods, and the Scarlet-fruited kind (*S. racemosa*), a native of the south of Europe, is very ornamental in warm, sheltered localities; but the species represented in the annexed woodcut, though one of the most floriferous of all, is seldom met with either in our own tree nurseries or on the Continent: it is a native of the Southern United States and of California. M. Carrière informs me that it has been recently introduced into French gardens, and moreover,

Californian Elder (*Sambucus californica*).

that it is a very ornate and desirable small-flowering tree, blooming from the middle of May till frosts set in. It is more graceful in habit than the Common Elder, and its numerous terminal and axillary corymbs of white, agreeably odorous flowers give it quite a distinctive character. It may be readily propagated by means of cuttings or layering, and young plants are well adapted for shrubby borders, as they flower freely when only a few feet in height. B.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Melon-beds.—Those who have to grow their Melons in ordinary garden frames on beds of fermenting material, and who have not at command a plentiful supply of hot manure, should not commence operations too early in the season, but a bed should now be made up in which to turn out the plants raised from seeds some weeks back. To succeed well Melons require more warmth at the root even through the summer than Cucumbers; consequently, it will be advisable to make a good substantial bed 4 ft. or 1½ ft. in depth, of well prepared manure, with, if obtainable, a plentiful addition of leaves, as this, with the assistance of the increased sun-heat, will keep up sufficient warmth until the plants have made considerable progress. See that the soil for the bed, if too wet from exposure to rain, is placed under cover where it will dry sufficiently before putting in the frame; use nothing but ordinary loam, if of a strong, heavy nature, all the better, for Melons, unlike Cucumbers, do not require manure in the soil.

Cucumbers.—During the recent cold, windy weather, Cucumber beds into which the plants were placed some time ago will be likely to have become too cold. Where this has occurred at once apply linings of fresh manure, 3 ft. in width and well surrounding the frame. It is much more economical, in both labour and material, to commence with substantial linings than to do the work piecemeal. As the roots of the plants appear through the surface, add soil which has been kept for a day or two up against the sides of the frame till it has become warm before placing it in contact with them; do not make it over-rich by the addition of too much manure. When Cucumbers are over-stimulated in this way it frequently causes them to become diseased, and as the soil gets exhausted any manurial assistance they require can be administered to them by means of manure-water. See that the plants are regularly syringed every afternoon, otherwise aphides and red spider are almost sure to make their appearance. As the weather gets warmer, and the plants come into a strong bearing condition, many people are under the impression that it is unnecessary to use tepid water, yet such is by no means the case: many failures in Cucumber-growing are attributable to the neglect of this precaution. Water should always be administered at a temperature of 70° or 80°, and even if 10° or 15° higher no harm will ensue, but rather be an advantage. Vegetable Marrow seeds should now be put in; place them singly in small pots, as by this means, when potted on, there will be no disturbance of the roots.

Herbaceous Borders, Shrubberies, &c.—Now, when deciduous trees and shrubs are bursting into leaf, and numerous herbaceous plants are coming into flower, the grounds should be made neat and orderly. Any protecting material, such as straw or Fern, that has not been removed, should be cleared away from Pampas Grass, Tritomas, or any subject that has been similarly protected. Any herbaceous borders that have not yet been dug should have a few inches of the top forked over, being careful not to go too deep so as to disturb the roots, which, in the case of most of these plants, are now in an active growing condition; as the work proceeds, so break the surface with the fork sufficiently, so that it may have a neat appearance without resorting to the rake, which tends to solidify the soil in a way that prevents either sun or air acting upon it; and in a season like the present, when the ground is unusually wet, a surface evenly raked also prevents its drying properly. Take advantage of the first opportunity, when the top is sufficiently dry, to hoe shrubby ground where there is any appearance of weeds, especially Grass, which is a great deal more difficult to contend with than ordinary summer weeds, and if in existence at all in the autumn, has through the mild winter kept on growing, until in many places it almost presents the appearance of having been sown; where the soil is very heavy, and weeds are more difficult to destroy by hoeing, in some cases it may be necessary to resort to digging them into the ground, although unless there be an accumulation of Grass or weeds, I should never advocate digging amongst shrubs, as it inevitably destroys the surface-roots, which are the most essential to the plants. Do not attempt to rake off weeds that have been thus hoed up until the ground has got quite dry, or in their removal too much soil will necessarily be taken off with them.

Rose-beds, containing either standards or dwarfs, should be dug over, giving where required a good dressing of manure, which dig in as the work goes on. Dwarf Roses, that are grown on the system of pegging down horizontally the previous summer's shoots, should be so treated without delay, otherwise only a portion of the eyes near the extreme end to where these growths have been pruned back will break, leaving those near the base dormant. Amateurs who have not adopted this method of Rose growing will not be disappointed should they give it a trial, as for general decorative purposes Roses so managed are very superior to either full-sized or dwarf standards, or bushes left in an upright position, especially for beds on lawns, where their effect is infinitely preferable; but to reap the full advantages of the system, Roses so grown should be on their own roots, as then whatever growth they make in the shape of suckers is rather an advantage than otherwise, for these strong suckers make the best blooming wood for another year. Another matter to be observed in Roses thus treated is that the strongest-growing kinds are planted in the centre of the beds, gradually coming down to the sides with such as are of a less vigorous disposition; and where the weaker Tea sorts will succeed, they should occupy the outside, as also the Moss varieties, which are more low and spreading in habit than the Hybrid Perpetuals.

Lawns and Grass Verges should be well swept to remove all wormcasts, and, where necessary, rolled previous to being mown, for although most of the machines profess to roll as well as cut the Grass, yet if mowing be attempted where the ground is full of worm-casts without their being previously removed, a single operation will do more to injure the cutting capabilities of any machine than half-a-dozen mowings when the surface is free from grit. The existence of Moss on lawns is produced in two ways—a wet condition and extreme poverty of the soil caused by the exhaustion resultant from continuous mowing, and the non-supply of enriching material to enable it to afford nourishment to the Grass. Where Moss exists from the latter cause, a dressing of lime and ordinary loam (one part of the former to three parts of the latter), scattered on about 1 in. in thickness, will be of the greatest benefit in destroying the Moss and promoting the growth of the Grass. By an immediate application when the advanced season furthers more rapid growth, its slightly unsightly appearance will be of short duration. Where the sowing recommended some time ago has not grown satisfactorily, a sprinkling of Grass seeds may be put on at the same time; this renovating will be found especially beneficial under deciduous trees.

Wall Climbers.—It frequently happens that flowering plants, such as Roses, Clematises, or others that are employed for clothing walls, are indifferently trained at the commencement, by which inattention they very soon get nearly or quite bare at the bottom, making the best growth, and producing almost all their flowers at the top of the wall, however high this may be. In growing fruit trees on walls, the skilful operator is careful to train a sufficient number of strong branches low down in a horizontal position, so as to balance the growth, and to keep the bottom of the wall as well furnished as the middle and top. If the same care were taken with flowering plants, when employed for the purpose of covering walls, the subsequent effect would be much more satisfactory. Where large plants have been allowed to run up and become naked at the bottom, there is no resource but either partially or wholly heading them down. Those consisting of a few strong, and the remainder weaker branches, should have the strong ones headed down near the base of the plants, which will cause them to break out, and the shoots they produce may be arranged so as to clothe the bottom of the wall, retaining the weaker growths, which will obviate the bare appearance that results from a total cutting back. Over the walls of buildings or on those of a considerable height, a very good effect may be produced by planting Pyracantha, Cotoneaster, Pyrus japonica, and other plants of a similar character, in order to clothe the bottom of the wall with Clematises, Roses, Honeysuckles, Jasmines, Passifloras, or Wistarias to train over the top. Where any alteration is required in wall coverings, the present will be found a good time to attend to it. There is one cause through which wall plants, especially Roses, frequently suffer to such an extent as to render it impossible for them to have a pleasing appearance: this is through such insects as green fly or red spider being allowed to increase upon them unchecked. From the warmth which the wall affords, these pests generally appear upon such plants as they can live upon earlier than on those growing in an open position; and as rain has but a poor chance of effecting the removal of the insects, on account of the shelter afforded by the wall, the plants are almost wholly dependent upon the use of the syringe or garden engine for their riddance from these marauders; a plentiful supply of clean water alone, if applied sufficiently early and continuously as required, will keep the insects in check, but if a good look-out be kept, so as to detect them when they first make their appearance in spring, and a thorough

syringing be given with Quassia or Tobacco-water, it will generally be found an effectual preventive. Climbing plants that thus receive sufficient attention thrive and flower very differently from those that exist under a state of neglect.

Kitchen Garden.—In late, cold districts where the land is wet and heavy, the planting of late Potatoes has been necessarily deferred during the present spring later than usual; it should now be hurried forward with all convenient speed. In many places the soil in which the early Potatoes were planted has, through continued wet, become almost as close and solid as if it had never been dug. Where this is the case, as soon as they are sufficiently aboveground to distinguish the rows, it will be well to fork the soil over between these, but this must be done before the tops have made much progress and the roots consequently advanced far, or they will be disturbed, and their proper development seriously interfered with. Salads.—Continue to make sowings of small salad and Radishes at short intervals in rich soil, so as to promote quick growth, without which they will be tough. Sow more Lettuce now, and from this time forward in the rows where they are to be grown, so as to avoid the check they receive in transplanting from a seed-bed.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

April 30.—Potting offsets taken from old plants of Echeverias, and shifting Balsams into larger pots. Sowing Cockscombs, Celosia pyramidalis, and another crop of French Beans. Trimming and tying in shoots of creepers in conservatory. Watering recently planted Yews. Digging beds in Rose garden. Mulching Strawberries out-of-doors with short straw. Levelling Celery land for Winter Greens. Staking Hyacinth spikes in beds out-of-doors. Dusting Turnips with lime and soot, in order to kill fly. Thinning frame Carrots. Earthing up Cauliflower, and mulching Vine and Peach borders with rotten manure. Digging land for main crop of Turnips, and raking all rough flower borders. Clipping Box edging, clearing land of Winter Greens, and hoeing between all growing crops.

May 1.—Potting Dr. Lindley and Vesuvius Pelargoniums for conservatory decoration; also Musk, Celosias, and Calceolarias. Repotting Lycastes. Sowing Mignonette in pots, and another row of Sweet Peas; also sowing mixed flower seeds among Rhododendrons, another crop of Veitch's Perfection and Champion of England Peas, Spinach, and Radishes. Watering Vine and Peach borders inside houses. Making beds for sowing Cauliflower, Lettuce, and Cabbage seed. Earthing up Potatoes, and top-dressing Cucumbers. Cutting flower-spikes from Rhubarb. Stopping and tying down Vine shoots. Hoeing among herbaceous plants. Putting all Roses that have been forced into cold pits.

May 2.—Potting Caladiums, Perilla, Sedum variegatum, Capsicums, Chillies, and Vegetable Marrows. Keeping East Indian Orchid-house moist night and day, and putting top shades on Stanhopea-house. Sowing Victoria Stocks, ornamental Grasses, Clarkias, Colinusias, and Nemophilas; also Turnips among bush fruit trees, and more Spinach between newly-sown rows of Queen of the Marrow Peas on a north border. Planting Violets in beds, herbaceous plants, Myosotis, and Cerastium; also Sir Harry Strawberry plants that have been forced and duly hardened off. Pricking off Saponaria calabrica, Daisies, Stocks, and Aubrietias. Putting in cuttings of scented-leaved Pelargoniums. Refilling another pit for Cucumbers. Tying in Peach tree shoots in houses in order to expose the fruit to light and sunshine. Top-dressing inside Vine borders with cow-manure, digging land for French Beans, and watering Turnips and Cauliflowers. Tying up more Lettuce for succession, and hoeing among Cabbage and Cauliflower plantations.

May 3.—Potting off Globe Amaranthus, Lobelia, Bouvardia, Plumbago, Fuchsias, and cuttings of stove plants. Repotting Vallota purpurea, Palms, and Pomegranates, planting the latter in a leaf-bed. Shifting tree Mignonette and Celosias into 8-in. pots; also Tomatoes. Sowing another batch of Balsams, Cinerarias, Calceolarias, and Cockscombs; also a bed of Walcheren and White Cape Broccoli, Marjoram and Sweet Basil; likewise Syon House Cucumber, Legg's Melon, and a crop of Scarlet Runners. Planting Asparagus, Celery, Globe Artichokes, Vegetable Marrows, and Tomatoes. Pricking off Marigolds, Lobelias, Asters, Phlox Drummondii, and other annuals in cold frame. Putting in Pink and Carnation cuttings. Plunging Tuberoses out-of-doors. Turning manure for Celery. Syringing Muscat Vines to keep down red spider. Top-dressing Lilies in pots and plunging

them in a sand-bed close to a wall with peat and cow-manure. Filling up vacant spaces in Asparagus-bed. Earthing up Potatoes, and digging land for Parsley and Cabbages.

May 4.—Potting off *Tropeolum canariense*, Primulas, and *Scutellaria* cuttings. Shifting Standard Pelargoniums and Heliotropes into the pots in which they are to flower, and placing them in a late Vinery; also potting young Fuchsias and *Disa Herschelli*. Putting up Phalacropsis shades on north side of house, and commencing to give Dendrobies, Lycastes, and *Lælia autumnalis* more copious supplies of water. Sowing Peas in trenches which had previously been heavily manured; also a few more rows of Broad Beans amongst Currant trees. Planting Lily of the Valley and *Spiraea japonica*; also Gladioli in well-manured ground. Fertilizing Melons as fast as they come into flower, and keeping them at a temperature of from 65° to 70°. Syringing Plum trees with soft soap and Tobacco-water in order to kill black fly. Raking round Rose trees to make the ground available for sowing Mignonette seed. Thinning Apricots and Peaches. Taking up Broccoli and placing it in a cool cellar. Digging land for French Beans and Lettuces, and sulphuring pipes in Vineries to keep red spider in check.

May 5.—Sowing prickly Spinach, Parsley, Chervil, Ridge Cucumbers, Scotch Kale, White Cape, Backhouse's Winter, Surprise, Champion, and Eclipse Broccoli, and another bed of Radishes and a little Cauliflower. Planting Madame Falcot Roses. Staking and tying Pelargoniums and Clarkias; also tree and other Mignonette. Pricking out East Lothian Stocks. Thinning Muscat and other Grapes. Watering Beans, Carrots, Potatoes, Celery, and seed beds with weak guano-water. Tying Figs in house. Disbudding Peach and Nectarine trees out-of-doors. Digging ground for late Peas. Looking over Rose trees for maggot. Netting Sweet Peas to keep off sparrows. Clearing away long litter from Rhubarb and Globe Artichokes, and burning old Asparagus roots and other rubbish.

Notes on Hardy Flowers.

ASTERS.—Complaints are being made on every hand as to the inferior growth of Aster seeds. This is just what might have been expected, for the drought of last year prevented the perfect maturation of the seeds; and the German growers announced in their lists that they would have to fall back upon seed harvested in 1875. Raisers of Asters must nurse their plants to the best of their ability, and not be in too great a hurry to throw away the contents of their seed-pans. A further sowing might be made without delay. Perennial Asters, if planted out now, will soon get established. A few of the best are *A. alpinus*, *A. altaicus*, *A. Amellus*, *A. elegans*, *A. multiflorus*, and *A. pyrenaicus*. There is scarcely another flower that supplies hues of purple, violet, and blue in autumn as these Asters do, and if grafted in a good sandy loam they cannot fail to thrive.

BALSAMS.—Seeds of the main crop of Balsams should now be coming through the soil, and it is not too late to sow a little more seed for succession. To have a few plants in flower early, the leading seedlings should be potted singly into thumb pots, and grown on in a brisk heat. Many Balsams are completely spoiled by leaving the plants too long in the seed-beds; or potting them in too large pots, when they become drawn and spoilt. Unless the roots of Balsams soon find their way to the sides of the pots, the plants become lanky and attenuated. Balsams in pots require a rich soil and plenty of water.

CARNATIONS.—Plants of the perpetual or tree kinds will now be coming into full bloom, and will require to be kept free from attacks of green fly, and they should also be well watered. Those who force flowers for market like to have blooms as early as possible, but for general purposes it is desirable to have them in flower in April, May, and June. This also applies to forcing Pinks; of the latter I have lately seen Miss Gibbons, a fine pure white, and coccinea, bright scarlet, in fine condition; Derby Day and Lord Lyon, two very fine purple varieties are fast coming on to succeed them.

CARNATIONS AND PICOTEES.—Those who grow fine selections of these will now have them in 10-in. and 12-in. pots, three plants of one variety in a pot; they should for the present be protected from heavy rains, but as soon as the weather becomes settled the pots may be set out-of-doors on a cinder-ash bed. Early varieties will be making some advancement towards blooming, and the shoots will require staking. As the old foliage decays, it should be cut away with scissors, an operation which greatly improves the appearance of the plants. Any blooms thrown up from the bottoms of the plants on short stems should be removed. The surface soil to beds of Carnations and Picotees will require stirring after so much rain, and a top-dressing of rotten manure and loam mixed together will be found to be of great advantage to them.

LOBELIAS.—Seedling plants of bedding kinds should be pricked off into boxes, or beds made up in cold frames, to encourage them to grow, and also to harden them off preparatory to their being planted out in the open ground. Plants wintered in pits will now be growing freely, and may be divided if necessary. Plants of the herbaceous or cardinalis type—a class well deserving of more extended cultivation—should now be potted for blooming or planting out in a well-prepared bed. Amongst these there are now many pretty varieties, and a bed of them in flower has a fine appearance.

MINULUSES.—Plants of selected varieties of these held over from last year and re-potted at the end of March or early in April, will now be showing bloom under glass. They should therefore be fully exposed to the sun and freely watered. During hot weather a cool north house is the best place for them. Seedlings are progressing fast, and should be potted off and encouraged to grow. A bed of Minuluses is a charming sight in the open ground. True, heavy rains soon disfigure them, but a hot, sunny day quickly restores them to their wonted beauty.

PHLOXES AND PENISIEMONS.—A bed of the herbaceous Phloxes should now be made. The plants should be well established in pots before being planted out, as then they quickly root into the soil. Penstemons require to be similarly treated, and during warm, moist, growing weather, they make rapid headway.

SWEET WILLIAMS.—In many places Sweet Williams have done badly, owing to the winter having proved so wet. As soon as the weather will admit of its being done, the surface soil of the beds should be stirred, and a top-dressing of loam and manure applied. A bed of Sweet Williams, to be really effective, should have the leading shoots tied to stakes, or the wind will blow the plants about and make a wreck of many of them. The flowers of a good strain are so bold in appearance, so varied in character, and so handsomely marked, that they will repay a little extra attention at the proper time.—D.

Forwarding Asparagus.—Asparagus may be obtained a month before it is ready out-of-doors as follows:—About the middle of February place some movable wooden frames over a permanent bed of it, and with a few barrow-loads of warm manure and leaves make up a lining all round the bed, and cover its surface with dry hay. Then put on the lights and keep them closed for three weeks, when the heads will begin to appear. The hay should then be cleared off, and a little air given on every favourable opportunity. Under this treatment I cut my first Asparagus on March 20, and since that date I have cut several hundreds of beautiful heads, and still they promise to be sufficiently abundant to keep up a good supply until the outdoor crop is ready. By this plan the bed, which does not experience any disturbance, will last a great number of years, provided its produce is not cut too late. Cutting should cease and the glass be removed directly the outdoor crop is ready.—H. HARRIS, *Denne Park, Ipsham.*

Peas in Trenches.—As a precaution against drought in the case of mid- or a-on crops, I consider this a decidedly beneficial and satisfactory mode of growing Peas. Although last season was exceptionally dry and hot, our crop of Peas treated in this way was excellent. The trenches were prepared as for single rows of Celery about 6 ft. apart, with a good quantity of old Mushroom-bed manure forked into them, and, as soon as the Peas were up and staked, a good mulching of half-decayed manure was applied, by means of which one good soaking of water kept the soil moist for a considerable period. Thus managed, tall sorts, such as British Queen, No Pius Ultra, and Champion of England, continued to furnish successful gatherings quite as long as we have had them in more favourable seasons when grown on level ground. In the case of Scarlet Runners, Cantiflowers, and similar crops, some portion of the crops should also be planted in trenches as a precaution against drought.—J. GROOM, *Ilkham.*

French Beans for Winter Use.—Mr. Gilbert (see p. 271) will find the following an excellent plan for preserving French Beans for use in winter. It is a plan which has been practised here for years, and I have never known it to fail. It obviates, indeed, the necessity of growing them in pots. We use jars for the purpose similar to those employed for storing eggs, put in the jar first a layer of salt and then a layer of Beans, and so on alternately till full, with plenty of salt between the layers, so that when it becomes brine, the Beans are well covered. When the Beans are required for use, soak them in water for at least twenty-four hours, then cook them in the usual fashion. Beans for preserving should be gathered when young.—THOMAS BRUCEHAM.

—H. R. says, cut the Beans as for cooking, then place them in alternate layers of salt and Beans in an earthenware jar, finishing with a layer of salt; cover the jar to keep out the dust, but not so as to be air-tight, and keep it in a cool dry place.]

PLATE LXXI.

ZONAL PELARGONIUMS

(WITH A COLOURED FIGURE OF LEAMINGTON LASSIE).

Drawn by J. WHITEHEAD.

Few families of plants are of more importance in a decorative point of view than Pelargoniums, more particularly the Zonal or Horse-shoe section, the exceedingly diversified and numerous varieties belonging to which are supposed to be the result of blending together two closely-allied species—viz., *P. zonale* and *P. inquinans*. The former was introduced to this country about the year 1710, and the latter a few years afterwards. *P. zonale* is distinguished by the more or less dark horse-shoe mark upon its foliage, while the leaves of *P. inquinans* are plain green, and the flowers are characterised by broader petals. Few if any species of plants have better repaid the exertions of the hybridizer than these two Pelargoniums, although for several years after their introduction to English gardens no attempts, so far as is known, were made in that direction. Sir Thomas Moore, in his "Flower Garden Displayed," mentions the introduction to this country from the Paris gardens of a striped-leaved variety of *P. zonale* or *P. inquinans* as early as the year 1732, and this may possibly have been the same variety as is alluded to by Miller in the "Gardener's Dictionary," published in 1768. But the earliest record of any distinct variety of Pelargonium having originated in this country is that of Dr. Fothergill, who obtained a variety from seed to which his name was given, and it is probable that from this plant the various varieties of the modern nosegays may have been principally derived. It would, however, appear that for many years no successful attempts were made to obtain improved varieties of these plants, which were then known by the name of scarlet Geraniums, and, as the name implied, the flowers were all of that colour, with narrow petals, while the plants were of a straggling habit, with large and coarse foliage; and it is comparatively within the last few years that these plants have been so greatly improved as regards habit of growth, the ornamental character of their foliage, size of truss, form of individual bloom, breadth of petals, &c.; and the comprehensive term of zonal Pelargonium now includes varieties with flowers of all shades, from the most intense scarlet or the deepest purple, from which the blue element is not altogether absent, to the purest possible white, while in size and form the blooms are nearly all that can be desired. There are also now many beautiful varieties bearing double and semi-double flowers, which are held in high estimation by some growers, and they certainly possess an advantage over the single sorts, inasmuch as they retain their petals until the bloom withers, and this persistent property renders them exceedingly useful as regards the production of cut flowers. Although the double Zonal Pelargoniums are a comparatively recent introduction to this country, one variety at least with double flowers has long been grown on the Continent, and the late Dr. Neill, of Edinburgh, mentions having seen at Ghent a variety of *P. inquinans* or *P. zonale* with double flowers as early as the year 1817; and it is possible that it was this variety which was at a much later period introduced to this country under the name of *Triomphe de Gergovia*. Its origin, however, is unknown, and it possessed no merit as a decorative plant; but its pollen was used by M. Lemoine to fertilize blooms of the well known pink-flowered Zonal *Beauté de Suresnes*, and from this union *Gloire de Nancy* was obtained about the year 1864 or 1865, and this may be considered as the first really deserving double Pelargonium raised. Since that time many very beautiful double-flowered kinds have been raised in this country as well as on the Continent, and M. Jean Sisley, of Lyons, appears to have succeeded in originating a very distinct race of plants of a dwarf and compact habit of growth, with very large semi-double flowers of various shades of colour. He was also the first to raise a double white variety, viz., *Aline Sisley*, about the year 1872. The first really white-flowered Zonal Pelargonium with broad petals was introduced to this country from the Continent under the name of *Madame Vaucher*, about the year 1860, and this variety was for some time a great favourite. Previous to that time there had been introduced several kinds, with very

light pink-coloured blooms, with narrow petals, and of but little merit as ornamental plants, all of which were, of course, eclipsed by this variety; and although various additional white-flowered kinds have been introduced since, it may be questioned if any of them are greatly in advance of the sort just named. About the year 1848, Mr. Kinghorn, using the pollen of Miller's variegated Pelargonium, a narrow-petalled variety of unknown origin, which has been already alluded to, upon some broad-petalled Zonal sort, succeeded in originating a silver-margined or variegated variety, of great value as a bedding plant, which was well known under the name of Flower of the Day; and this was followed by numerous meritorious variegated kinds by other raisers. For many years what appeared to have been a variegated or golden-margined sport from *P. inquinans* (but as to its positive origin nothing was for certain known) might have been occasionally met with in the greenhouses, and even in the plant stoves of this country, cultivated more as a curiosity than as a really use-

introduction of a variety whose blooms are stated to be striped and flaked like the finest Carnation.

The subject of the accompanying illustration is a Pelargonium that takes a very high, if not the highest rank, in the section to which it belongs, having received a first-class certificate from the Royal Horticultural Society in July, 1876. It is the result of a cross between Louise Delsales and Master Christine; it was raised in 1875 by Mr. J. H. Hawley and sent out by Messrs. Parsons & Co., of the Ranelagh Gardens, Leamington. It is compact and robust in habit, and free-flowering, throwing well up from the plant large trusses of semi-double pink flowers. It is as free-flowering as Vesuvius, and for decorative purposes stands almost unrivalled, blooming, as it does, freely throughout the winter. Where cut flowers are in request, Leamington Lassie will be a decided acquisition, the blooms, when cut, being very persistent and good in colour.

P. GRIEVE.

Culford.

Common Hepatica (*Hepatica triloba*).

Creeping Forget-me-not (*Omphalodes verna*).

Double-flowered bulbous Crowfoot (*Ranunculus bulbosus fl.-pl.*).

Horned Tulip (*Tulipa cornuta*).

Alpine Soldanella (*Soldanella alpina*).

Early Tulip (*Tulipa præcox*).

ful decorative plant: this was known by the name of Golden Chain, and I believe that the late Mr. D. Beaton was the first to discover its value as a bedding plant, or, rather, as an effective plant for margins of beds. In the summer of 1855 I fertilized blooms of several Zonal varieties with the pollen of Golden Chain, and the result was the well-known Mrs. Pollock, the first of the race of Golden Tricolors, or variegated Zonal Pelargoniums. The very beautiful varieties known as Bronze Zonals, or Bicolors, had a similar origin. During the last few years various raisers, whose names are too numerous to mention here, but which include the late Mr. Pearson, of Chilwell, Dr. Denny, and many others, have been devoting attention to the improvement of the flowers and habit of growth of the green-leaved section of the Zonal Pelargonium. Their exertions in this respect have been attended with the greatest amount of success which could have been expected. But perfection has by no means as yet been arrived at. As each succeeding season only tends to develop new and enhanced forms of beauty, even the ensuing season will, it is said, witness the

HARDY FLOWERS IN LONDON GARDENS.

NARCISSI still make a fine display in some of the London nurseries; perhaps the most attractive kinds now in bloom are *N. Horsfieldi*, Double Sulphur Phoenix, *N. bicolor*, *N. muticus*, and the Yellow Hoop-petticoat (*N. Bulbocodium*), the latter growing in beds literally covered with bright golden blossoms borne on stalks not more than 2 in. in length; a variety of *N. poeticus* called *augustifolius* is also very attractive; its cut blooms may now be seen in large quantities in Covent Garden. Several varieties of Iris are now flowering freely, notably the Dwarf Flag Iris (*I. pumila*); *Iris biflora*, too, is putting forth a number of rich purple blossoms. Early summer Squills are now abundantly furnished with spikes of bright blue blossoms, especially such kinds as *Scilla campanulata*, *S. patula*, and *S. amona*. The Globe-flowers (*Trollius asiaticus*, *T. europæus*, and *T. altaicus*), are producing bright golden, globular blossoms in abundance, and the Blood-root (*Sanguinaria canadensis*) is also just pushing its ivory-white flowers through the soil. The Comfrets (*Symphytum*

caucasicum and album), are now laden with drooping clusters of blue, purple, and white bell-shaped blossoms, and tufts of the double-flowered Wood Anemone (*A. nemorosa* fl.-pl.) are studded with buds and blossoms on rockwork at Tottenham. Here, too, may also be found the brilliantly-coloured Tulipa Greigi, the yellow *T. sylvestris*, and the prettily striped *T. Clasiana*, all finely in bloom; *Primula denticulata* and *P. viscosa* are likewise flowering freely in favourable situations, and the Grape Hyacinths (*Muscari Heldreichi* and *M. neglectum*) are equally attractive. *Leucojum pulchellum* is furnished with multitudes of beautiful Snowdrop-like blossoms, which are very ornamental when used in bouquet or other floral devices. In addition to the above, the following are also flowering freely at Kew and other places, viz., *Orobus vernus*, *Saxifraga Webbiana*, *Lasthenia glabrata*, an annual which sows itself freely, and is among the most valuable of Composite plants for spring flowering. Associated with these may likewise be seen *Pulmonaria angustifolia* and *P. saccharata*, and *Adonis vernalis*. The white Wood Lily (*Trillium grandiflorum*), and *Trillium erectum*, a maroon-purple kind, are also in flower. *Helleborus caucasicus*, too, is bearing numbers of dark purple drooping blossoms.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 310.)

Eryngoos.

Falshp. Let the sky rain Potatoes; let it thunder to the tune of Green Sleeves, hail kissing comfits, and snow Eryngoos.

Merry Wives, act v., sc. 5.

Gerarde tells us that Eryngoos are the candied roots of the Sea Holly (*Eryngium maritimum*), and he gives the recipe for candying them. I am not aware that the Sea Holly is ever now so used, but it is a very handsome plant as it is seen growing on the sea-shore, and its fine foliage makes it an ornamental plant for a garden. But as used by Falstaff I am inclined to think that the vegetable he wished for was the Globe Artichoke, which is a near ally of the Eryngium, was a favourite diet in Shakespeare's time, and was reputed to have certain special virtues which are not attributed to the Sea Holly, but which would more accord with Falstaff's character. I cannot, however, anywhere find that the Artichoke was called Eryngoos.

Fennel.

(1) *Ophelia.* There's Fennel for you and Columbines.
Hamlet, act iv., sc. 5.

(2) *Falstaff.* He plays at quoits well, and eats conger and Fennel.
2nd Henry IV., act ii., sc. 4.

Like all strongly-scented plants, the Fennel was supposed to abound in "vertues," which cannot be told more pleasantly than by Longfellow:—

Above the lowly plants it towers,
The Fennel with its yellow flowers,
And in an earlier age than ours
Was gifted with the wondrous powers—
Lost vision to restore,
It gave men strength and fearless mood,
And gladiators fierce and rude
Mingled it with their daily food:
And he who battled and subdued—
A wreath of Fennel wore.

The English name was directly derived from its Latin name *Feniculum*, which may have been given it from its hay-like smell (*fœnum*), but this is not certain. We have another English word derived from the Giant Fennel of the south of Europe (*ferula*); this is the *ferule*, an instrument of punishment for small boys, also adopted from the Latin, the Roman schoolmaster using the stalks of the Fennel for the same purpose as the modern schoolmaster uses the cane.

As a useful plant, the chief use is a garnishing and sauce for fish. Large quantities of the seed are said to be imported to flavour gin, but this can scarcely be called useful. As ornamental plants, the large Fennels (*F. tingitana*, *F. campestris*, *F. glauca*, &c.) are very desirable where they can have the necessary room.

Fern.

Godshill. We have the receipt of Fern-seed—we walk invisible.

Chamberlain. Now, by my faith, I think you are more beholden to the night than to Fern-seed for your walking invisible.

1st Henry IV., act ii., sc. 1.

There is a fashion in plants as in most other things, and in none is this more curiously shown than in the estimation in which Ferns are and have been held. Now-a-days it is the fashion to admire Ferns, and few would be found bold enough to profess an indifference to them. But it was not always so. Virgil gives the Fern a bad character, speaking of it as "flicem invisam." Horace is still more severe, "neglectis urenda filix innascitur agris." The Anglo-Saxon translation of Boethius spoke contemptuously of "the Thorns, and the Furzes, and the Fern, and all the weeds" (*Cockayne*). And so it was in Shakespeare's time. Butler spoke of it as the

Fern, that vile, unuseful weed,
That grows equivocally without seed.

And later still Gilpin, who wrote so much on the beauties of country scenery at the close of the last century, has nothing better to say for Ferns than that they are noxious weeds, to be classed with "Thorns and Briers, and other ditch trumpery." The fact, no doubt, is that Ferns were considered something "uncanny and eerie;" our ancestors could not understand a plant which seemed to them to have neither flower nor seed, and so they boldly asserted it had neither. "This kinde of Ferne," says Lyte in 1587, "beareth neither flowers nor seede, except we shall take for seede the black spots growing on the backsides of the leaves, the whiche some do gather thinking to worke wonders, but to say the truth it is nothing els but trumperie and superstition." A plant so strange must needs have strange qualities, but the peculiar power attributed to it of making persons invisible arose thus:—It was the age in which the doctrine of signatures was fully believed in; according to that doctrine Nature, in giving particular shapes to leaves and flowers, had thereby plainly taught for what diseases they were specially useful. Thus a heart-shaped leaf was for heart disease, a liver-shaped for the liver, a bright-eyed flower was for the eyes, a foot-shaped flower or leaf would certainly cure the gout, and so on; and then when they found a plant which certainly grew and increased, but of which the organs of fructification were invisible, it was a clear conclusion that properly used the plant would confer the gift of invisibility. Whether the people really believed this or not we cannot say, but they were quite ready to believe any wonder connected with the plant, and so it was a constant advertisement with the quacks. Even in Addison's time "it was impossible to walk the streets without having an advertisement thrust into your hand of a doctor who was arrived at the knowledge of the Green and Red Dragon, and had discovered the female Fern-seed. Nobody ever knew what this meant" ("Tatler," No. 240). But to name all the superstitions connected with the Fern would take too much space. Its history as a garden plant is, however, worth a few lines. So little has it been esteemed as a garden plant that Mr. J. Smith, the ex-Curator of the Kew gardens, tells us that in the year 1822 the collection of Ferns at Kew was so extremely poor that "he could not estimate the entire Kew collection of exotic Ferns at that period at more than forty species" ("Smith's Ferns, British and Exotic"—Introduction). Since that time the steadily increasing admiration of Ferns has caused collectors to send them from all parts of the world, so that in 1866 Mr. Smith was enabled to describe about a thousand species, and now the number must be much larger; and the closer search for Ferns has further brought into notice a very large number of most curious varieties and monstrosities, which it is still more curious to observe are, with very few exceptions, confined to the British species.

Figs.

(1) *Titania.* Feed him with Apricocks and Dewberries,
With purple Grapes, green Figs, and Mulberries.
Midsommer Night's Dream, act iii., sc. 1.

(2) *Constance.* An' its grandam will
Give it a Plum, a Cherry, and a Fig.
King John, act ii., sc. 1.

- (3) *Guard*. Here is a rural fellow
That will not be denied your Highness's presence,
He brings you Figs.
Antony and Cleopatra, act v., sc. 2.
- (4) *1st Guard*. A simple countryman that brought her Figs. *Ibid.*
Ditto. These Fig-leaves
Have slime upon them.—*Ibid.*, act v., sc. 2.
- (5) *Pistol*. When Pistol lies, do this; and Fig me, like
The bragging Spaniard.
2nd Henry IV., act v., sc. 3.
- (6) *Pistol*. Die and be damned, and Figo for thy friendship.
Fluellen. It is well.
Pistol. The Fig of Spain.
Henry V., act iii., sc. 6.
- (7) *Pistol*. The Fig for thee, then.
Ibid., act iv., sc. 1.
- (8) *Iago*. Virtue? a Fig?
Othello, act i., sc. 3.
- (9) *Ditto*. Blessed Fig's end!
Ibid., act ii., sc. 1.
- (10) *Horner*. I'll pledge you all, and a Fig for Peter.
2nd Henry VI., act ii., sc. 3.
- (11) *Pistol*. Convey, the wise it call; steal! a Fico for the phrase.
Merry Wives, act i., sc. 3.
- (12) *Charman*. O excellent! I love long life better than Figs.
Antony and Cleopatra, act i., sc. 2.

In most of these quotations the reference is simply to the proverbial likeness of a Fig to a matter of the least importance. But, in the others, the dainty fruit, the green Fig, is noticed. The Fig tree, celebrated from the earliest times for the beauty of its foliage, and for its "sweetness and good fruit" (Judges ix., v. 11) is said to have been introduced into England by the Romans; but the more reliable accounts attribute its introduction to Cardinal Pole, who is said to have planted the Fig tree still living at Lambeth Palace. Botanically, the Fig is of especial interest. The Fig, as we eat it, is neither fruit nor flower, though partaking of both, being really the hollow, fleshy receptacle enclosing a multitude of flowers, which never see the light, yet come to full perfection and ripen their seed. The Fig stands alone in this peculiar arrangement of its flowers, but there are other plants of which we eat the unopened flowers, as the Artichoke, the Caper, and the Clove.

Filberts.

- Colibus*. I'll bring thee to clustering Filberts.
Tempest, act ii., sc. 2. (See Hazel).

Flax.

- (1) *Ford*. What, a hodge-pudding? a bag of Flax?
Merry Wives, act v., sc. 5.
- (2) *Clifford*. Beauty that the tyrant oft reclaims
Shall to my flaming wrath be oil and Flax.
2nd Henry VI., act v., sc. 2.
- (3) *Sir Toby*. Excellent, it hangs like Flax in a distaff.
Twelfth Night, act i., sc. 3.
- (4) *3rd Servant*.
Go thou: I'll fetch some Flax and white of eggs
To apply to his bleeding face.
King Lear, act iii., sc. 7.
- (5) *Ophelia*. His heard was as white as snow,
All Flaxen was his poll.
Hamlet, act iv., sc. v.
- (6) *Leontes*. My wife deserves a name
As rank as any Flax-wench.
Winter's Tale, act i., sc. 2.

The Flax of commerce (*Linum usitatissimum*) is not a true native, but it takes kindly to the soil, and soon becomes naturalized in the neighbourhood of any Flax field or mill. We have, however, three native Flaxes in England, of which the smallest (*L. catharticum*) is one of the most graceful ornaments of our higher downs and hills. The Flax of commerce, which is the plant referred to by Shakespeare, is supposed to be a native of Egypt, and we have early notice of it in the Book of Exodus; and the microscope has shown that the cere-cloths of the most ancient Egyptian mummies are made of linen. It was very early introduced into England, and the spinning of Flax was the regular occupation of the women of every household, from the mistress downwards, so that even Queens are represented in the old illuminations in the act of

spinning, and "the spinning-wheel was a necessary implement in every household, from the palace to the cottage" (Wright—"Domestic Manners"). The occupation is now almost gone, driven out by machinery, but it has left its mark on our language, at least on our legal language, which acknowledges as the only designation of an unmarried woman that she is "a spinster."

A crop of Flax is one of the most beautiful, from the rich colour of the flowers resting on their dainty stalks. But it is also most useful; from it we get linen, linseed-oil, oilcake, and linseed-meal; nor do its virtues end there, for "Sir John Herchel tells us the surprising fact that old linen rags will, when treated with sulphuric acid, yield more than their own weight of sugar. It is something even to have lived in days when our worn-out napkins may possibly reappear on our tables in the form of sugar" (Lady Wilkinson).

As a garden plant the Flaxes are all ornamental. There are about eighty species, some herbaceous and some shrubby, and of almost all colours, and in most of the species the colours are remarkably bright and clear. There is no finer blue than in *L. usitatissimum*, no finer yellow than in *L. trigynum*, no finer scarlet than in *L. grandiflorum*.

Flower-de-Luce.

- (1) *Perdita*. Lilies of all kinds,
The Flower-de-luce being one.
Winter's Tale, act iv., sc. 3.
- (2) *King Henry*. What sayest thou, my fair Flower-de-luce?
Henry V., act v., sc. 2.
- (3) *Messenger*. Cropped are the Flower-de-luces in your arms,
Of England's coat one half is cast away.
1st Henry VI., act i., sc. 1.
- (4) *Pucelle*. I am prepared; here is my keen-edged sword
Decked with five Flower-de-luces on each side.
Ibid., act i., sc. 2.
- (5) *York*. A sceptre will I have, have I a soul,
On which I'll toss the Flower-de-luce of France.
2nd Henry VI., act v., sc. 1.

Out of these five passages, four relate to the Fleur-de-luce as the cognizance of France, and much learned ink has been spilled in the endeavour to find out what flower, if any, was intended to be represented, so that Mr. Planché says that "next to the origin of heraldry itself, perhaps nothing connected with it has given rise to so much controversy as the origin of this celebrated charge." It has been at various times asserted to be an Iris, a Lily, a sword-hilt, a spear-head, and a toad, or to be simply the Fleur de St. Louis—Adhuc sub judice lis est—and it is never likely to be satisfactorily settled; I need not therefore dwell on it, especially as my present business is to settle not what the Fleur-de-luce meant in the arms of France, but what it meant in Shakespeare's writings. But here the same difficulty at once meets us, some writers affirming stoutly that it is a Lily, others as stoutly that it is an Iris. For the Lily theory there are the facts that Shakespeare calls it one of the Lilies, and that its other way of spelling is Fleur-de-lys. I find also a strong confirmation of this in the writings of S. Francis de Sales (contemporary with Shakespeare); "Charity," he says, "comprehends the seven gifts of the Holy Ghost, and resembles a beautiful Flower-de-luce, which has six leaves whiter than snow, and in the middle the pretty little golden hammers" ("Philo," book xi., Mulholland's Translation). This description will in no way fit the Iris, but it may very well be applied to the White Lily. Chaucer, too, seems to connect the Fleur-de-luce with the Lily—

Her nekke was white as the Flour de Lis.

These are certainly strong authorities for saying that the Flower-de-luce is the Lily. But there are as strong or stronger on the other side. Spenser seems to separate the Lilies from the Flower-de-luces in his pretty lines—

Strow mee the grounde with Daffadow-Dillies,
And Cowslips, and Kingcups, and lovéd Lillies;
The pretty Pawnee
And the Chevisaunce
Shall match with the fayre Flouré Delice.

Shepherd's Calendar.

Lord Bacon also seems to separate them: "In April follow the double White Violet, the Wall-flower, the Stock-Gillflower, the Cowslip, the Flower-de-luces, and Lilies of all natures."

In heraldry also the Fleur-de-lis and the Lily are two distinct bearings. Then, from the time of Turner in 1568, through Gerarde and Parkinson to Miller, all the botanical writers identify the Iris as the plant named, and with this judgment most of our modern writers agree. We may, therefore, assume that Shakespeare meant the Iris as the flower given by Perdita, and we need not be surprised at his classing it among the Lilies. Botanical classification was not very accurate in his day, and long after his time two such celebrated men as Redouté and De Candolle did not hesitate to include in the "Liliaceæ" not only Irises, but Daffodils, Tulips, Fritillarias, and even Orchids.

What Iris Shakespeare specially alluded to it is useless to inquire. We have two in England that are indigenous—one the rich golden-yellow (*I. Pseudacorus*), which in some favourable positions, with its roots in the water of a brook, is one of the very handsomest of the tribe; the other *I. (fœtidissima)*, with dull flowers and strong-smelling leaves, but with most handsome scarlet fruit, which remain on the plant and show themselves boldly all through the winter and early spring. Of other sorts there is a large number, so that the whole family, according to the latest account by Mr. Baker, of Kew, contains ninety-six distinct species besides varieties. They come from all parts of the world, from the Arctic Circle to the South of China; they are of all colours, from the pure white *Iris florentina* to the almost black *I. Susiana*; and of all sizes, from a few inches to 4 ft. They are mostly easy of cultivation and increase readily, so that there are few plants better suited for the hardy garden or more ornamental.

Fumiter, Fumitory.

- (1) *Cordelia*. Crowned with rank Fumiter and furrow weeds.
King Lear, act iv., sc. iv. (See Cuckoo-flowers).
- (2) *Burgundy*. Her fallow leas
The Darnel, Henlock, and rank Fumitory
Doth feed upon.
Henry V., act v., sc. 2.

Of Fumitories we have five species in England, all of them weeds in cultivated grounds and in hedgerows. None of them can be considered garden plants, but they are closely allied to the *Corydalis*, of which there are several pretty species, and to the very handsome *Dielytras*, of which one species—*D. spectabilis*—ranks among the very handsomest of our hardy herbaceous plants. How the plant acquired its name of Fumitory—*fume-terre*, earth-smoke—is not very satisfactorily explained, though many explanations have been given; but that the name was an ancient one we know from the interesting Stockholm manuscript of the eleventh century published by Mr. J. Pettigrew, and of which a few lines are worth quoting. (I take them from Lady Wilkinson's "Weeds and Wild Flowers"):

Fumiter is erbe, I say,
Yt spryngyth i April et (and) in May,
In feld, in town, in yard, et gate,
Yer (where) lond is fat and good in state,
Dan red is his flour
Ye erbe smek (smoke) lik in colour (colour).

Furze.

- (1) *Ariel*. So I charmed their ears,
That, calf-like, they my lowing followed through
Toothed Briars, sharp Furzes, pricking Goss, and Thorns.
Tempest, act iv., sc. 1.
- (2) *Gonzalo*. Now would I give a thousand acres of sea for an acre of
barren ground, long Heath, brown Furze, anything.
Ibid., act i., sc. 1.

We now call the *Ulex europæus* either Gorse, or Furze, or Whin; but in the sixteenth century I think that the Furze and Gorse were distinguished (see Gorse), and that the brown Furze was the *Ulex*. It is a most beautiful plant, and with its golden blossoms and richly-scented flowers is the glory of our wilder hill-sides. It is especially a British plant, for though it is found in other parts of Europe, and even in the Azores and Canaries, yet I believe it is nowhere found in such abundance or in such beauty as in England. Gerarde says, "The greatest and highest that I did ever see do grow about Excester, in the West Parts of England;" and those who have seen it in Devonshire will agree with him. It seems to luxuriate in the

damp, mild climate of Devonshire, and to see it in full flower as it covers the low hills that abut upon the Channel between Ilfracombe and Clovelly is a sight to be long remembered. It is, indeed, a plant that we may well be proud of. There is a well-known story of Linnaeus that when he first saw the Furze in blossom in England he fell on his knees and thanked God for sparing his life to see so beautiful a part of His creation. The story may be apocryphal, but we have a later testimony from another celebrated traveller who had seen the glories of tropical scenery, and yet was faithful to the beauties of the wild scenery of England. Mr. Wallace bears this testimony:—"I have never seen in the tropics such brilliant masses of colour as even England can show in her Furze-clad commons, her glades of wild Hyacinths, her fields of Poppies, her meadows of Buttercups and Orchises, carpets of yellow, purple, azure, blue, and fiery crimson, which the tropics can rarely exhibit. We have smaller masses of colour in our Hawthorns and Crab trees, our Holly and Mountain Ash, our Broom, Foxgloves, Primroses, and purple Vetches, which clothe with gay colours the length and breadth of our land" ("Malayan Archipelago," vol. ii., p. 296).

As a garden shrub the Furze may be grown either as a single lawn shrub or in the hedge or shrubbery. Everywhere it will be handsome both in its single and double varieties; and as it bears the knife well, it can be kept within limits. The upright Irish form also makes an elegant shrub, but does not flower so freely as the typical plant.—H. N. ELLACOMBE.

(To be continued).

FLORA OF THE COAL PERIOD.

M. GRAND'EURY has made the flora of the upper coal measures his special study, and notably those of the valley of St. Etienne. The annexed illustration, prepared from original drawings by M. Grand'Eury, gives, in "La Nature," the relative height and position of the plants, which constitute the coal vegetation of that district, consisting chiefly of Ferns, Lycopods, and Equisetums. Tree Ferns are scarce at St. Etienne, though frequently found in coal-pits in other localities. Equisetums, on the contrary, are very plentiful, and of gigantic size. Conifers, Cycads, and Palms appear to have formed the greater part of the carboniferous plants, and to have contributed immensely to the formation of coal. Towards the end of the coal era vegetation became much developed, and immense forests covering a large portion of the submerged land sprang up. M. Elie de Beaumont has made a calculation as to the amount of charcoal which our forests annually produce, and according to him this material would only make a deposit of 0.016 of a foot of coal in a century. M. Dumont has counted eighty-five beds of coal at Liège, some of which are about 2 ft. in thickness; admitting that the mean thickness of each seam would average 0.60 of a foot, the forests now in existence must continue to accumulate their substance for nearly 500,000 years before they could form a deposit sufficient to yield a bed 2 ft. in thickness. The left half of the annexed woodcut represents two species of Calamites, fossil plants of the ancient coal formation, having the general appearance of Equisetums, but sometimes attaining the height of trees; on the right, or other half, will be found Sigillarias, Lepidodendrons, and Cordaites, all plants, or rather trees, which also belong to the carboniferous era, and which, together with Tree Ferns, geologists tell us constituted at that time the characteristic vegetation of the globe.

The Paradise Stock.—I have the true Paradise stock in flower, and a very ornamental bush it is. The Doucin (a little later) is also coming into flower. There is a remarkable difference in the strength of the two kinds, the Paradise being always dwarf and compact, and the roots near the surface.—J. H.

Young Trees Best.—Planting trees of an early age, says a writer in an American journal, is productive of early and prolonged fruitfulness. We often see fine specimens of fruit growing on trees yet in the nursery row. Peach trees older than one year are worthless here. Young trees in the hands of a skillful grower can be made to assume almost any shape, which cannot be said of those of an advanced age. Young trees can be made to branch so low that neither Grass nor Weeds will grow under them on account of the shade, and I am not sure but this would be a good method with some kinds. The prolific Peach Trees in some American orchards rest their branches on the ground when loaded with fruit. However, for general culture a medium height is perhaps most desirable. [It may be added that many English fruit growers are becoming aware that it is better to plant young trees than such as have become established, after grafting, in nursery rows.—B.]

Two species of Calamites.

Sigillarias. Lepidodendrons.

Cordaites.

EXAMPLES OF THE COAL FLORA.

THE INDOOR GARDEN.

RENOVATING HARD-WOODED PLANTS.

It often happens that a collection of hard-wooded greenhouse plants gets into a bad state of health; the foliage assumes a yellow tinge, is deficient in quantity, and the annual growth made is of the most meagre and unsatisfactory description. This state of affairs may arise from various causes, such as neglect at some period of the growth of the plants, errors in general treatment, choice of unsuitable soil, &c. Such plants as Camellias, Azaleas, Acacias, Cytisus, Coronillas, Myrtles, Oranges, and New Holland plants in general, are very liable to fall into this condition, and when this is the case none of the ordinary modes of culture will suffice to restore them to their normal vigour. In order to cure a disease we must first discover what has caused it, and in the present instance the source of evil will generally be found at the root. There are two mistakes into which many are apt to fall in the culture of hard-wooded plants, viz., not giving sufficient drainage, and shifting too often or into too large pots. As the generality of plants of this description require to be placed in the open air during a portion of the summer and autumn, they are of course liable to get drenched by heavy rains, and if not pretty well established before being turned out and well insured against stagnation of water in the soil, the roots soon become inactive, the soil gets permanently sour, and a chronic state of bad health sets in, which nothing but thorough radical measures will set right. A very slight experience in the way of plant-growing will enable any one to ascertain if the root be healthy or not, but there is one unfailing test, and that is, if the plant has been a season in the pot, the soil should be well filled with fibre; if this be not the case, it may be at once concluded that matters have been in some way mismanaged—that there has either been over-potting, or the use of unsuitable or imperfectly prepared compost. There are some plants which do not readily admit of being renovated, such, for instance, as Cape Heaths; if, after attaining a certain size these lose much of their foliage, but little can be done to bring them into good condition again; if they have become naked and unsightly, the better way is to destroy them, and get free-growing young plants in their places. With the greater portion of the hard-wooded tribe, however, much more can be done to bring old and apparently worn-out specimens again into a good healthy state. It may be said, why not get rid of a collection which has thus degenerated, and start afresh with young and healthy plants? But many are reluctant to part with plants which they have had in their possession for years perhaps, and which are regarded somewhat in the light of old friends, and around which many old associations may linger. Specimens of hard-wooded plants, too, are not quickly formed, and therefore it is worth some little trouble to restore to health what one has. Certain rules as regards soil are often laid down, but this I consider a mistake, as the treatment of plants must be varied according to the circumstances under which they are placed.

When and How to Renovate.

The best time to set about the inspection and renovation of hard-wooded plants is the month of March, inasmuch as at this time the roots begin to grow and the sap to circulate. Plants potted, too, at this period have sufficient time to enable them to fairly establish themselves in the new soil before they are induced to make any great effort in the way of growth. At this season, too, there is generally more time at command than later, and if advantage be taken of inclement weather, when outdoor work cannot be carried on, what labour may be necessary can be thoroughly and carefully performed. The principal requisites will be a stock of well-sweetened soils of various kinds, clean pots, and drainage; also neat sticks of suitable length and strength. The soils to be used should have been exposed for at least a year to the action of the atmosphere. Loam is a good soil for many kinds of plants, but there is a wide difference in the quality of it as obtained from different localities. The term loam is often indiscriminately applied to any material between sandy turf and clay; much of the so-called loam that I have seen employed has been nearly destitute of fibre, and therefore wholly un-

suitable for potting, except for plants having roots of the strongest description. It is sometimes rather difficult to procure really good turfy loam, and when this is the case it is safer to put up with a lighter and somewhat poorer soil, and rely upon subsequent feeding to supply any deficiency that there may be in the way of nutriment. On turning a sickly plant out of its pot, one generally finds the extremities of the roots discoloured or wholly absent, owing to their having been destroyed by contact with sour soil; the latter, if carefully probed with a sharp-pointed stick, will come away in lumps, thus indicating a deficiency of fibre: we must therefore endeavour to remove as much of such mould as we possibly can, and replace it with something more suitable. This work is best performed when the ball is in a rather dry state, as it is then lighter to handle, and after as much of the old soil has been extracted in the manner just described as is possible without injury to the root, the ball may be gently tapped with the palm of the hand, when a considerable portion of the remaining soil will fall away. All decayed roots should be pruned off with a sharp knife, and if the plant be small enough to handle, it should be dipped in water, and then placed where the superfluous moisture can drain away. If it be too large to be thus treated, the roots may be sprinkled with a fine-rosed watering-pot. The advantage arising from this latter operation is that heavy waterings are rendered unnecessary for a time; the pots and drainage must, however, be damped, and the compost should be used in a moist state, in order to ensure full benefit therefrom. A pot should then be chosen into which the roots can only just be conveniently placed, for the less soil used the better, provided there is enough to surround the roots, amongst which it should be gently worked; by tapping the pot on the bench, the soil will settle gently into its place; hard potting is to be avoided, but the surface must be made firm, for if left loose the soil is apt to get into a muddy state. These directions apply more particularly to plants whose roots can be easily traced in the soil, and which as a rule require loam, leaf-mould, or a mixed compost. Plants that require peat to grow in can hardly be managed in this way; their roots are so fine and often so like the soil in colour, that it would be dangerous to remove much of it. The best way to treat this class of plant is to allow the soil to dry out, and then, after removing the old drainage, to tap the ball vigorously with the hand. This will bring away as much of the old mould as is consistent with safety; soak the ball, and let the surplus water drain away; the plant may then be replaced in the same-sized pot, as the object is merely to give just enough new soil to stimulate the roots into healthy action.

Soils of Different Kinds.

In the choice of soils for a mixed collection of plants, the operator must be guided by the appearance of each particular plant and the state of its root. The general rule to be observed is that the more weakly and debilitated the specimen the lighter the soil should be. I have myself completely restored old Myrtles, Oranges, Oleanders, &c., from a miserable state of decrepitude into good, free, healthy plants by simply reducing the size of the pot or tub, and using a very light sandy soil. It will, of course be understood that there are certain families of plants which will only thrive in a certain soil, such as Heaths, Epacris, and many New Holland plants; for them the best peat is absolutely necessary, and no other soil can well be employed. But most other genera are more accommodating; the Camellia, for instance, will luxuriate in either loam, peat, or leaf-mould, or a mixture of any or all of them. For our present purpose a mixed compost will be found the most suitable; about a third of each kind, with enough silver sand to render the whole free and light, will suit the greater portion of them. It must not be supposed that there will be any sudden or magical change effected hereby; the first season will be devoted to the production and preservation of new roots; it will only be in the course of the second or third season that the full benefit of this operation will be realized. After potting care must be taken in watering, giving it only when required, but insuring at the same time the perfect saturation of the ball. On bright sunny days they should be syringed once or twice, as otherwise the evaporation will be in excess of the root-power to supply the water. By the time

the hot weather arrives they will have struck fresh roots, but a little shade should be afforded them, and it is not advisable to turn them out-of-doors until well established; in fact, only those that appear to be doing very satisfactorily should be set outside, otherwise it is better to leave them the first season entirely under cover. Insect plagues, such as scale, thrips, fly, &c., must be kept in check; those plants possessing comparatively large and stiff foliage, such as Camellias and Oranges, should be well washed before being fresh potted. If treated as just described, the greater portion of the plants will be found by the end of the season to have pretty well filled the pots with healthy fibre. Next spring, therefore, they may be shifted into pots of a larger size, when they will make vigorous growth.

Pruning.

They should not be pruned the first season, as this can only be ventured upon where there is a command of bottom-heat; but if the pots be well filled with roots the second year, they may be cut back to the old wood, and this may be done fearlessly. Old straggling Azaleas may be cut in right to the old wood; the closer they are pruned, in fact, the more vigorous will be the succeeding growth. Such things as *Cytisus*, Camellias, Acacias, may all be operated on in this way with advantage, as strong, healthy growth, and a shapely plant will thus be obtained, which will amply repay the labour expended, and will be preferable either to throwing the plants away or allowing them to drag on from year to year in an unhealthy and unshapely condition.

JOHN CORNHILL.

Bullet.

REED MAT PROTECTORS OR COVERINGS.

WHERE unheated pits and frames are in constant use, some kind of external covering in addition to the glass is absolutely necessary, if the subjects to be wintered in them be at all tender. Where good Russia mats are sufficiently plentiful to be laid two or three thick upon frames, an ordinary winter may be safely passed through; but in addition to these, the great variety of plants that fall under the designation of bedders require some slight protection in the spring when they are passing from their winter to their summer quarters. Nearly all the coverings that I have seen in use or have been advocated in THE GARDEN lack the most essential qualifications of being light and portable, easy to put on and take off by one person, and capable of being stored away when not in use like Russia mats. In describing what are here called Reed mats (which our labourers make during wet weather), I may safely assert that they are a combination of all the good qualities of Russia mats with a much greater facility of resisting extremes of cold; any ordinarily handy workman can make them, and the only material necessary is a good stock of Reeds (stored in the autumn), with some strong tar rope and string. Having decided on the size of the mats (which is, of course, guided by the size of the frames or pits to be covered), four stout pieces of wood are nailed together as a temporary framework, and long nails 1 ft. apart, are inserted at the top and bottom, to which are fastened stout strands of tar rope, which act as ribs to the mats; then, commencing at the bottom, small bundles of Reeds (about twelve in each) are laid alternately the heads one way and the stems the other, whereby the mat is kept of an even thickness throughout; round each of these we fasten a smaller strand of tar string tightly round the straight strands or ribs with a loop or half-hitch knot, which binds the whole firmly together. When the required length is completed, the ends of the strings are loosened from the nails and plaited together, which form a very strong edging at top and bottom, and the ends are cut off level with a pair of shears; they may then be rolled up and tied round until required. These mats when in use offer the following advantages, viz., they will roll on or over a frame more easily than any kind of covering which I have yet seen; do not require fastening to prevent displacement by wind; and will dry themselves if stood on end—therefore always ready to resist frost. They carry rain off from any covering used in addition like a thatch, and being composed of straight hollow tubes, have a great power of acting as non-conductors of either heat or cold. I have tried many kinds of coverings, such as framework covered with oil-cloth, &c., which is a very useful way of covering Vine borders to carry off excessive heat, but as regards their power of resisting frost, they are inefficient. In this neighborhood good Reeds from 7 ft. to 9 ft. high are abundant, and of scarcely any commercial value, but in districts where they may not be so easily obtained, the straightest and stoutest straw that could be obtained would, with a slight modification in the mode of construction, make a very serviceable covering.

J. GROOM.

THE CINERARIA AND ITS CULTURE.

THE fine display afforded by the Cineraria at this season of the year and onwards reminds one that it is time to think of preparing for another season. To have Cinerarias in flower during the winter and spring and early summer, they should be propagated both by seed and by offsets; the latter plan is adopted chiefly in multiplying named sorts. It is still time to sow seed. A small packet of it if good will produce a sufficient number of plants for autumn and winter work, and for the later display it is much better to propagate named kinds, as they are altogether superior to seedlings. The seed should be sown in fine light soils in a shallow pan, and barely covered, and should be raised in a temperature of 60°; the pan should be covered with a pane of glass till the seedlings come through, and from first to last the soil must never be allowed to become dry; Cinerarias like and require a constantly moist soil. As the seedlings grow, they should be pricked out into other pans or shallow boxes, always employing a light, open compost, consisting of two-thirds loam, and one-third leaf-mould and sand and decayed manure. When the plants get too large for boxes, they should be potted into 4-in. or 5-in. pots, and from these, before they get pot-bound, into 8-in. or 9-in. ones, as a final shift. From the time they are fairly established in the boxes till they have done flowering, they should receive little or no assistance from fire-heat, but be grown on in cool frames during the summer behind a north wall if possible, and by September they may be placed in the cold greenhouse to flower.

Named varieties begin going out of flower towards the end of April and onwards till June. As fast as the flowers fade, the plants should be cut down and stowed away in a cold house or pit and kept watered, and at intervals during May and June they should be partially shaken out at the root and planted up to their collars on a north or east border, and in a free light soil, placing each kind in a row by itself for convenience. Here they will simply want deluging with water in dry weather, and by July they will be pushing numerous offsets from which the next stock must be raised. Our plan is to take off one batch—say 150—in July, another in August, and the last in September. Each offset is potted in a 4-in. pot as soon as taken off, and the plants are set as closely together as they will stand in a cold frame or a north aspect. Here they are watered and cared for till fairly established, when they are shifted into their flowering pots, and again transferred to the cool frame, from which they are, however, all removed by October to the greenhouse, where they remain till they come into flower. The pots are always well drained, but during their whole season of growth the plants are kept as cool and moist as possible. For weeks at a time during the dead of winter, the temperature of the Cineraria house seldom rises above 45° day or night, for no fire-heat is used except to exclude frosts; but the plants grow and thrive amazingly, and are never affected by green fly, which under other circumstances is the worst enemy of the Cineraria. Little need be said as regards general culture, except that the plants should never be pinched or staked—they require neither as a rule. Offsets lifted in time and treated generously, and shifted on in good time, will not show flower too soon; but if they do, the spikes should be pinched out. We never pinch a second time after the plants go into their flowering pots, and the flower-stems are always vigorous, the trusses broad, and the flowers large and of good substance. When the plants are fairly established in their pots, they require much water, which must be supplied unstintingly, and very weak liquid manure may be given every time they are watered, or about twice a week; but by giving a little every time they are sure not to be missed.

C.

HYBRIDIZING PRIMROSES AND POLYANTHUSES.

EARLY in last May I offered a few suggestions on the probable means of obtaining new and improved varieties of fancy Primroses and Polyanthuses. At that time only about a score of my second year's seedlings had bloomed, but they were so promising as to induce me to describe how they had been produced; since then the entire lot, consisting of over 700 plants, have flowered, fully confirming and even exceeding the favourable opinion that had been formed of their good properties; it is therefore with considerable confidence that I venture to urge my former advice, viz., that to secure a complete break as regards constitution, colours, markings, form, size, and scent, it is necessary to cross Primroses and Polyanthuses with the ultimate intention of re-crossing their hybrids with each of the normal species until an improved race of both is permanently established. A few of my giant Polyanthuses that have been raised by these means are very beautiful, showing a marked advance over old-established and named varieties; one of them, a delicate mauve, is peculiarly attractive; some are as brilliant as *Vesuvius*; others are of a darker shade, larger and better than *Auriculiflora*; another has crimson flowers

2½ in. in diameter; while several are as sweetly perfumed as the Rose. Many of the Primroses, too, are equally pleasing.

Last year only a small number of my seedlings were flat and circular, this season dozens of them possess both features, showing increased brightness of colour and distinctness of markings; all these advantages have proceeded almost exclusively from a very limited collection, comprising Vesuvius and a few named Primroses supplemented by my own seedlings, all which varieties, with the exception of altaica and a scarlet Primrose, have this season been dispensed with. The impossibility of procuring suitable sorts with which to work compelled me to apply the pollen of long-styled plants to each other; this necessity probably explains why a portion of my seedlings have produced very small flowers. My next or third year's seedlings will suffer from similar disadvantages, but with the possession of numerous improved varieties, I may reasonably hope that the plants raised from this year's seeds will not be readily surpassed in beauty. Owing to the persistent ravages of the larvæ of the *Oliorynchus*, only a very imperfect opinion can be formed of the merits of my productions, every plant having been injured by the attacks of from two to six grubs, which so seriously affected their roots as to render it necessary to wash all the soil from them; consequently at present not one of them is well established; and unless means can be adopted to overcome this difficulty, either the cultivation of Primroses will have to be abandoned, or else they will have to be treated as annuals.

Under favourable circumstances Primroses may be rendered available for winter blooming, for, notwithstanding the numerous drawbacks that mine have had to encounter, they have flowered in the Fern-house from October to the present time, and it is probable that they will yet last for several weeks; and had these plants been in vigorous health, there would have been a grand display during the winter and spring months. Though the pollen of leading varieties was freely used in crossing, not a single seedling exactly resembles either the male or seed-bearing parent, proving the strong tendency that these have to sport, and at the same time offering great encouragement to the hybridist. *Primula suaveolens* though a true (Swiss) Cowslip, differing considerably from *P. veris* in foliage, colour of the flower, and also in the eye, was crossed with either *P. elatior* or *P. acaulis*, and about forty seedlings were the result. Of these a few are true Cowslips, the flowers of which closely resemble those of *P. suaveolens*, while the foliage is similar to that of *P. veris*. Others in many respects can scarcely be distinguished from our northern Oxlip, indirectly pointing to the origin of that so-called species. Several of these seedlings have half assumed the orange-red of the scarlet Primrose, leading to the suspicion that this colour may be attributed to *P. veris*, and that with judicious crossing a true *Polyanthus* might be obtained, proving the latter to be only the developed hybrid of *P. veris* and *P. acaulis*.

Hybridising has varied the arrangement of the productive organs, for, though they are usually normal, there are many exceptions where the stigma protrudes one-eighth of an inch beyond the tube; often it just rises to the surface of the flower, while with others it rests almost on the anthers at the bottom of the tube; should this disturbance extend, it is possible that *P. acaulis* will eventually become monoecious. Most of the properties that were suggested last season as desirable are, I believe, substantially correct, though the form and size of the eye and the number of the lobes or petals are open for further consideration. For most selfs the eye cannot be too round, though its size must be regulated by the diameter of the flower, but for white and light coloured shades the same cannot be too large; it may also be round, radiated, or foliated. Six lobes usually ensure a round flower, and produce a good effect, and will possibly be the means of introducing double flowers; but several years must pass before these and many other difficulties, viz., how to obtain a perfect Primrose or Polyanthus, are solved.

A. CLAPHAM.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Choisya ternata.—This is a good plant when well grown, and the white flowers are sweet-scented. The leaves, however, have an odour that is not agreeable. It is nearly hardy, but is best grown in a cool house.—J. H.

Propagating Poinsettias.—These are often thought to be difficult to propagate, but I have never found them to be so. I do not start the old plants into growth and then make the young shoots into cuttings, but I cut up the stems into short pieces, with one eye or bud attached to each, as if propagating Vines, and place them singly in thumb pots filled with a mixture of sand and leaf-soil. The pots are then plunged in bottom-heat, but they also root freely without this, provided the soil is never allowed to become dry.—A NORTHERN GARDENER.

LOBELIA AXIFLORA.—This showy kind, with large and handsome orange-red and yellow flowers, is well deserving of culture; I have very seldom seen it in cultivation. It has Willow-like leaves, and is a free-grower in a cool greenhouse.—J. H.

HIP-ROOFED HOUSES OR PITS.

I READILY comply with "C. J. H.'s" request (see p. 264) for a few explanatory notes on these useful structures; and, in describing those alluded to at p. 190, I may as well state that they are by no means imposing-looking structures externally, being sunk in the ground level with the front wall plate; yet they fully realise "C. J. H.'s" opinion of being about as useful for general purposes as any kind of building that can be erected in a garden. When gardens are of any great extent, a show house or conservatory more or less lofty either attached or close to the mansion is a necessity; but the houses or pits whence the supply of forced products is to be derived need not rival lighthouses in loftiness; in fact, when external architectural appearance is the first consideration, the real purposes for which the buildings were erected is frequently altogether or partially frustrated; therefore a decided distinction should be made between growing and showing houses, for if the former be not adapted to the end in view, the latter will necessarily suffer by a lack of subjects, or at least by an inferior quality in the subjects to show. It is generally acknowledged to be an important consideration in plant culture that the nearer the plants are kept to the glass the better, especially during the dull days of late autumn and winter, when every ray of light that it is possible to obtain should be utilised; while as regards the amount of heating power necessary to raise the temperature of a pit similar to the above (where the amount of useless vacant space is reduced to a minimum)

Back lights on hinges for ventilation. Front lights slide on rollers for ventilation or convenience of emptying or re-filling pits.

and a house with elevated roof and side-lights, when exposed to severe frost or cutting winds, the advantage on the side of the smaller structure is at once apparent; besides which, when external coverings are applied during severe weather, a proportionate amount of dry heat will be economised with advantage both to the occupants and to the coal bill, which latter has of late years been a serious drawback to indoor gardening. As regards the interior arrangements which may be regulated according to the subjects in request, we plant the narrow back beds permanently for the supply of such flowers as Gardenias, Stephanotis, &c., in hottest divisions, and Tea Roses and similar plants in coolest ones. The front beds are filled with the best Oak or Beech leaves that can be got and trodden down quite firmly, which thereby maintain a gentle heat the whole season, and afford an excellent position for forwarding pot Vines, Roses, Eucharis and similar bulbs and shrubs, and various subjects that it is desirable to hasten to either flower or fruit; or Melons and Cucumbers are either planted at once, or as the demand for forced flowers diminishes. By having stop-valves and cross return-pipes in each compartment, a regular succession of temperature may be maintained, the efficiency of which would not be interfered with by the dimensions of such a structure. In erecting the pits above alluded to, I utilised a vacant space and spare materials, and although with a wider range of both external and internal appearances they might have been improved, yet the most important of all points in structures not intended for exhibition could scarcely have been improved, viz., answering the purposes for which they were erected.

Honham.

MIXED COLLECTIONS OF PLANTS FOR MARKET.

THE immense quantities of market plants that are yearly produced in some of the London suburban florists' establishments are not less astonishing than the perfection to which they are brought. Where only a few kinds of plants are grown and glass structures are specially provided for them, the trouble and care attending their culture are much less than what is required for a general collection of plants, inasmuch as in the latter case considerable forethought must be exercised in order to provide room for the various subjects just at the time when they require it by having others ready for removal to market. Perhaps a better illustration of general plant-growing for market could not be found near London than in the Brunswick Nursery, Tottenham. The ground which it occupies is but limited, but the houses by which it is almost entirely covered are made to produce healthy plants of various descriptions fit for market at all seasons of the year. The great advantage gained by having a mixed collection of plants is, that a few van-loads fit for market can at all times be made up, whereas, when only a few kinds are grown, blanks in the supply—and consequently in the incomes—frequently occur. Notwithstanding that Mr. Maller—the proprietor of the nursery in question—grows a great variety of subjects, he, in common with other market-growers, makes a few plants a speciality, the principal ones being Heaths, Spiræas, and Rhodanthes. Of Heaths, 30,000 are flowered and disposed of annually: these consist chiefly of *Erica gracilis*, *hyemalis*, *candidissima*, and *Willmoreana*, the two former being for winter and early spring flowering. Cuttings of these are struck on a very slight bottom-heat in winter, and when rooted, they are potted off three in small 3-in. pots, and placed in light, airy positions, as on shelves in the houses or in pits close to the glass. During March they are shifted singly into 3-in. pots, and when well rooted, are placed in cold pits and subjected to as much air, light, and sun as possible. In this state they remain throughout the summer, receiving abundance of water both overhead and at the roots. In the following winter they are cut down, and as soon as fresh growth commences, they receive their final shift into 5-in. pots, extra large plants being potted in 6-in. ones. They are potted in pure peat and sand, a soil in which they appear to grow as freely as scarlet Pelargoniums. Fire-heat is as much as possible avoided, coverings of mats, &c., being applied in preference during severe weather. Of *Spiræa japonica* about from 5000 to 6000 are grown; the roots of these are not imported, but are grown on Mr. Maller's own land. They are planted out in rich, moist soil, in a sunny situation, where they ripen their crowns perfectly. They are taken up and potted early in the autumn, kept copiously supplied with water, and forced gradually on in successive batches for winter and spring blooming. *Spiræa palmata* is also grown here, but not in such quantities as *S. japonica*.

Rhodanthes are probably more extensively cultivated here than in any other place near London, from 10,000 to 15,000 potfuls of them being grown annually. The seed, which is imported from Belgium, is sown at successive intervals from early in January until the end of April, in shallow wooden boxes. These are placed in gentle heat until the seeds have germinated, when they are removed to a lighter and more airy situation, and as the plants advance in growth all the air possible is admitted to them. When large enough to handle they are pricked off six or eight into a 6-in. pot, placed on the floors of the houses in light situations, and form a succession of bushy, well-flowered plants early in April and onwards through the summer. The varieties grown are *R. Manglesi* and *R. maculata*, and its white variety.

Fairy Roses form an interesting feature in this establishment, in which many thousands of them are grown, and a lovely sight they present when in full bloom. They are grown in 5-in. and 6-in. pots, in rich, sandy loam. A stake, placed in the centre of each pot, to which the main shoots are tied, induces the plants to assume a pyramidal, though by no means a formal shape. They grow about 6 in. or 9 in. in height, and about as much through, and in February, March, and April are covered with small, bright blossoms. Of *Cytisus racemosus* several thousands are grown here, and are remarkable examples of good cultivation, their long racemes of bright

golden Pea-shaped flowers standing well up above dense masses of healthy foliage. Cyclamens, too, are grown here in quantities. Their seed is sown in January, and the produce, grown on rapidly, forms excellent floriferous plants in 6-in. pots by the following autumn. A number of plants bearing the most perfectly formed and best-coloured blossoms are selected yearly from the stock, and placed by themselves for seed-bearing, and in this way the strain is each year improved. Clematises of different kinds are grown in the shape of pyramids, and when in flower they are either sold in the form of plants, or their blooms are disposed of in a cut state. Several houses are devoted to large white-flowered Azaleas, for furnishing cut blooms at Christmas and Easter, these being the seasons when white flowers are most in demand. A long span-roofed house supplies Roses for Easter; the plants are on their own roots and on the Manetti stock, and the strongest of the shoots are yearly pegged down to the bed in which they are planted, so as to entirely cover its surface; by this means a dense thicket of upright shoots is produced, each being thickly set with bloom-buds. The variety grown is General Jacqueminot, which is found to answer the purpose better than any other.

In addition to the above, there are thousands of Lily of the Valley from home-grown crowns, Fancy and Zonal Pelargoniums, *Ficus elastica*, Fuchsias, seedling Verbenas, and many other kinds of plants. Indeed, through the summer months over 100 dozen of various kinds are sent to market weekly. Among other plants *Sparmannia africana* is grown here for furnishing cut blooms, a purpose for which it answers admirably. Bedding plants of various descriptions are grown to fill up any spare room that may occur, and these being but a very short time on hand, little labour is incurred in their culture. There are also about twenty houses of various sizes and shapes, ranging from 60 ft. to 150 ft. in length, and every inch of space in them is utilized in the best manner possible. During summer, when Heaths, *Cytisuses*, and other plants are out-of-doors, Pelargoniums, Roses, *Spiræas*, &c., are principally disposed of, and the young stock can be placed in a small compass, the houses are filled with Ferns, Lycopods, *Poinsettias*, *Bouvardias*, and similar plants for sale late in the year and at Christmas. S.

Old Potatoes still the Best.—I have tried nearly all the new varieties of Potatoes during the last few years, but I have not yet met with any to supersede or even to equal the best of the old ones for general purposes. As regards earliness, I have found nothing so good as Myatt's and Hammermith Kidneys. As a second early kind Lapstone stands above all others; and for field planting Regents and Victorias are the best. I have not grown Snowflake largely, but I regard it as very promising. Have any of your correspondents noticed a falling off both in quantity of crop and size of tubers in the case of the Early Rose and other American sorts? Let me recommend all who intend planting Magnum Bonum to give it plenty of room. I planted some last season 2½ ft. by 2 ft. apart, and I was obliged to tie up the haulm to stakes.—J. BELL, *Strathfieldsaye*.

Berberis Darwini as a Hedge Plant.—Your correspondents do not refer to this plant as suitable for hedges. I have some experience in the matter, and I know of no better plant for that purpose. Its foliage is of a beautiful green all the year round, and when covered with orange flowers in April and May, it excites much admiration. It can be cut and trimmed with ease, and is as impenetrable as the Thorn. It is easily cultivated, and of very rapid growth.—W. V., *White Abbey*.

—A large *Berberis Darwini* was planted around the flower garden at Coldrenick, some years ago to make a screen, and nothing could have answered the purpose better. It is a quick grower, will bear close pruning, and is preferable to Holly in appearance. It should not be allowed to flower, for when-ever that occurs it looks patchy. This *Berberis* seeds freely and a stock of it can soon be got up. I would recommend any one who wants a handsome ornamental screen or hedge of any description to plant it. It does not do so well under trees as in open quarters.—J. D. NANCYAN, *Whiteaway*.

Vicomtesse Hericart de Thury Strawberry for forcing.—This has been superior to all other sorts here this season; among those first introduced to heat were Vicomtesse Hericart de Thury, Duc de Malakoff, and Keen's Seedling; and in the second batch were Vicomtesse Hericart de Thury, Duc de Malakoff, Keen's Seedling, La Grosse Sacree, and President, and in both cases Vicomtesse Hericart de Thury shows its superiority over all the others, being a better grower and setter, and producing quite three times as much fruit as any of its associates. Any one wishing to see these Strawberries may do so by paying us a visit.—J. WILLIAMS, *Dunortan, Tunbridge Wells*.

SOCIETIES AND EXHIBITIONS.

NATIONAL AURICULA SOCIETY'S SHOW.

CRYSTAL PALACE, APRIL 24.

THIS exhibition, which was in many respects highly interesting, showed conclusively that the taste for Auriculas and similar old-fashioned flowers has by no means died out as some had imagined. In all about 1000 plants were staged, and notwithstanding the lateness of the season, which more especially affected exhibitors from the North, the display was perhaps the best ever seen in the southern district, and the attendance of visitors was greater than had been anticipated. Northern growers were represented by the Rev. F. D. Horner, of Kirby-Malzeard, Ripon, and by Mr. Ben Simonite, Sheffield, both of whom were successful competitors, while Mr. Charles Turner, Slough, and Mr. James Douglas, Loxford Hall, Ilford, and other southern cultivators, had large and well-grown collections. The finest Auricula exhibited was George Lightbody, one of the best of all grey-edged flowers. Mr. Charles Turner showed a beautiful group of pot Roses and Azaleas, along with which were tastefully arranged well-grown plants of *Adiantum Farleyense* and other Ferns. The effective appearance of this group was also much enhanced by a background of tall Palms, *Dracenas*, *Aralias*, and other fine-foliated plants from the conservatories of the Crystal Palace Company. The tables on which the Auriculas were staged were also set off to advantage by means of the introduction of a central group of remarkably fresh-looking, well-arranged succulents, such as green and variegated *Agaves*, *Aloes*, *Kleinias*, and *Echeverias*, fringed with a line of the pale green *Sempervivum tabulaforme*, one of the most distinct and useful of all half-hardy decorative Houseleeks.

Auriculas.—In the class of fifty Auriculas in bloom, Mr. Charles Turner had a well-grown collection, both flowers and foliage being remarkably fresh and effective. In the show varieties Clipper (Turner) occupied a prominent place among self-coloured kinds, being a well-elevated, stout truss, of shapely, rich purple flowers; Garnet is also a desirable purple-coloured variety; General Neill (Traill) was in excellent condition, and one of the most brilliant and distinct of all grey-edged Auriculas; Colonel Champneys (Turner) was well represented; the ground colour of this variety is brilliant violet-purple, a tint which contrasts well with the dense white paste and bold, thickly-powdered foliage. Charles Perry (Turner) is another desirable, deep violet, self-coloured flower, bearing well-elevated trusses of flat and shapely pips, each about 1 in. across. Alpine varieties were well represented. In Mr. Turner's collection we noted *Perceval*, a vivid crimson; Mrs. Thomson, good both in texture and colour; Mrs. Carter, a dark crimson, nearly black, a colour intensified by a rich, clear, golden centre; Mrs. Llewellyn, a rich purple-tinted variety; and many others. Mr. J. Douglas was second in this class with a well-grown group, in which *Master Hale* and *Meteor Flag* were conspicuous, as were also *Vulcan* (Sims), a rich blackish-crimson; *True Briton* (Hepworth), a beautiful white-edged variety; and *Topsy* (Kay), a rich dark purple, of more than average merit. Mr. Douglas also had a white-edged variety named *John Waterston* (Cunningham) in excellent condition. Mr. S. Cooper, of the Hollies, Timperley, showed a good collection in this class. In the class of twelve varieties, the Rev. F. D. Horner had the best collection, Mr. B. Simonite, of Rough Bank, Sheffield, being second, and Mr. Douglas third. Among the varieties exhibited in this class the following deserve more than a passing notice, viz., *John Simonite*, an effective white-edged kind; *Charles Perry*; *Prince of Greens*; *Ann Smith*; *Pizarro*, a showy self-tinted-like crimson velvet; *Lancashire Hero* (Cheetham); and *Booth's Freedom*. Mr. Simonite had *George Lightbody*; *Spalding's Metropolitan*, a rich violet-purple self, a seedling of his own raising of a rich port-wine colour, with a good paste; and other good kinds. Mr. Douglas contributed *Charles Perry* (Turner), *Col. Champneys* (Turner), *Pizarro*, *Lancashire Hero*, *Lady Sale*, and the rich velvety-purple *Topsy*. In the class of six varieties, Mr. Horner was again first, Mr. Douglas second, and Mr. Simonite third; the varieties in the best group were *Pizarro*, *George Lightbody*, *Lancashire Hero*, *Smiling Beauty* (Heaps), *Prince of Greens*, and *Pizarro*. In the Alpine classes the principal awards were obtained by Mr. Charles Turner and Mr. J. Douglas, who had excellent and showy groups, some of the plants bearing six trusses; among these we especially noted *Queen Victoria* (Turner), a large-flowered variety, the paste of which is circular and of a delicate straw colour, the ground colour being rich velvety-purple edged with violet; *Nat Norman*, crimson; *John Ball* (Turner), a rich velvety-crimson with bright golden paste; *Dolly Varden*, maroon; *Fascination*, rich violet-purple; *Vesuvius*, crimson; and *Queen Eleanor*, a rich, velvety, violet-purple flower with pale sulphur paste. Mr. Douglas had good plants of *Miss Reid*, a delicate blue-tinted kind; *Sydney*, purple; *Beatrice*, a large, circular, purple flower with sulphur-coloured paste; and one or two vigorous and richly-coloured seedlings.

New Auriculas.—Not the least remarkable feature of this exhibition was the fine display of new Auriculas. Mr. B. Simonite had *Frank Simonite*, a white-edged flower of great beauty, the tube well coloured, the paste dense, pure, and smooth, the ground-colour black, the pip bold and rounded, and the truss large and well displayed. This will be a formidable rival to that queen among white-edged flowers, *Heap's Smiling Beauty*. The same exhibitor also had *Talisman*, broad, deep green edge, tube a little pale, dense smooth paste, black ground, large, bold pip, and smooth petal; *William Bradshaw*, a

fine grey edge, of bold and striking appearance and refined quality; and *Fanny Crossland*, white-edged, small as shown but full of promise, tube and paste good, the ground-colour dense and well displayed, and well-formed petal. These flowers all bid fair to take leading positions in their respective classes. The Rev. F. D. Horner showed Walker's *John Simonite*, a very fine white edge, the pip large but well proportioned, and very smooth, tube and paste good, body-colour dark—a flower that will be much sought after by cultivators. *Peacemaker*, a promising green edge, was shown by Mr. C. Turner: it has a golden tube, good, circular paste, dark ground, fine petal, and pip flat and circular. *Clipper*, also shown by Mr. C. Turner, is a fine, bold, dark self, tube and paste good, the body-colour glossy, black plum—a finely-formed flower.

Polyanthuses.—The best six Polyanthuses came from Mr. George Smith, Hedge Lane, Edmonton, who had gold-laced varieties, very similar in general appearance, bearing the following names:—*Rupert*, *Lothair*, *Gertrude*, *Retriever*, *Flora*, and *Garland*. Mr. Smith also obtained the first prize in the class for two Polyanthuses with *Advancer*, a rich gold-laced kind, and *Emma*, a less desirable flower. Mr. R. Dean, who was second with six well-grown Polyanthuses, had *Purity*, white; *Viceroy*, primrose; *marginata*, a white-edged, fancy variety; *Harlequin*, also a fancy kind; and *Mars* and *Sunrise*, both crimson-tinted varieties, well suited for decorative purposes. Mr. Dean also had *Polyanthus Buttercup*, a primrose and orange-tinted kind, with well-elevated umbels. The following, too, are robust, and admirably suited for decorative purposes, viz.:—*Avalanche*, double white and yellow; *Silver Line*, magenta-crimson with a white edge; *Purity*, a large, white, yellow-eyed flower; *Viceroy*, primrose, with an orange ray and good truss; and *The Bride*, white and orange, a smooth, broad-petalled flower. Mr. Hooper, *Widcombe Hill*, Bath, was awarded an extra prize for a group of seedling Polyanthuses and a beautiful collection of named Pansies, the flowers of the latter being large, smooth, and richly coloured. Mr. R. Dean obtained a similar award for a group of Polyanthuses, Auriculas, and other spring flowers, including cut blooms of the large, rich, scarlet-flowered *Anemone fulgens*. Messrs. Harrison & Sons, Leicester, sent well-grown examples of their new, large-flowered *Musk*, which is an improvement on the older varieties.

Royal Horticultural Society.—A good many of the would-be Guinea Fellows on our list, and others, have sent in their names here, or direct to the Society, as willing to become guinea members, but many have not yet decided how to act: perhaps the best hope of influencing them is in trying to show the present position of the Society. The nurserymen in and near London can, if they please, make the fortnightly shows at South Kensington beautiful ones: it will be worth their while to do so if enough of Fellows and of the public see the plants they exhibit. All the shows held this year have been good ones, there will, therefore, be good value for the guinea subscriptions of all living near London, and so it may be expected that very many new subscribers will join the Society. If this be so, whatever may have been the case in the past, it is probable that the South Kensington Garden will pay both its direct cost and that of furnishing it with plants grown at Chiswick: therefore there is no reason why all money subscribed by horticulturists in order to promote horticultural science should not be applied to purely horticultural purposes at Chiswick and elsewhere, and that the South Kensington Garden, instead of being a charge should be a benefit, as providing gratis a good place for committee meetings and shows. Among the nurserymen who make the shows some are, of course, really good horticulturists, but I think it should now be a great object to induce as many as possible of the best scientific horticulturists of the country to join the Society, as, until they do so, it will never be the great representative society which it should be. The guinea membership, with hope of a vote for country members hereafter, will help this; some of the very highest country horticulturists, among them the Rev. H. Harpur Crewe and Mr. George Maw have already become members or Fellows; and last, but not least, Mr. Isaac Anderson-Henry, of Edinburgh, has sent me his name to go in as a guinea member, with the hope of greater privileges hereafter. It is now of the greatest importance that as many well-wishers of horticultural science as possible should join the Society. It was feared by some that guinea fellowship or membership would stand in the way of the higher subscriptions; this appears not to have been the case. I may, perhaps, give one instance in proof of this—an old friend sent his name for our guinea list, but, when the time of joining the society came, he—for the sake probably of the transferable ticket—not only became a £2 2s. Fellow himself, but made his wife and daughter-in-law £2 2s. Fellows also.—*GEORGE F. WILSON, Heatherbank, Weybridge Heath.*

OBITUARY.

WE have to record with regret the death of Mr. David Cunningham, an event which took place at Moorpark, Hertfordshire, on the 17th inst., at the comparatively early age of fifty-seven. As a gardener he always held responsible situations, the duties of which he discharged with credit to himself and satisfaction to his employers.

Spring Water for Plants.—Our flower garden and rockery have to be supplied with water pumped into a 115-gallon cask, from a well 20 ft. deep in drift gravel. As the cask often has to be filled more than once a day in summer, the water cannot be long exposed to the air before it is used. If spring water be injurious choice Alpine and other plants, could anything be used to soften the water? and if so, what quantity should be put into a 115-gallon cask? There is not much, if any, lime in the water.—O.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

ASPARAGUS GATHERING AT ARGENTEUIL.—This is the season of gathering Asparagus at Argenteuil, and the process is interesting to the stranger. Asparagus knives of various forms are described in both French and English books, but one is confidentially told that they are only fitted for amateurs who do not care to soil their fingers. The good cultivators here never use a knife. Each crown or root is covered with a little mound of loose earth; through the top of this the tips of the strong, thick shoots are seen appearing. They are ready to gather when exactly 1 in. above the mould. In the light the young shoot first assumes a delicate rose-purple hue. It is not enough for the shoot to be visible on the surface; it must be 1 in. above it, so as to show the slightly rosy tip. The gathering occurs every second day about the end of April, but in May, when the growth is more active, the stools are gathered from every day. Given a shoot emerging from the earth ready to gather: the slightly hardened crust around the emerging bud is pushed aside, the fore and middle finger separate are then pushed deeply into the soft mould, pushing the earth outwards. If a rising shoot be met with on the way down, it is carefully avoided. A second plunge of the two fingers and pushing out of the earth usually bring them to the hardened ground about the crest of the root; the forefinger is then slipped behind the base of the shoot and pushed gently outwards, when the shoot at once snaps clean off at its base. This plan has the advantages of leaving no mutilated shoots or decaying matter in the ground. Here each plant of Asparagus is treated as a useful inhabitant of the Commune ought to be, and every cause of decay carefully avoided. Once gathered, care is taken that the shoot is not exposed to the light, but placed at once in a covered basket. As soon as the stalk is gathered, the earth is loosely and gently raked up with the hand so as to leave the surface of the mound as it was before, care being taken not to press the earth in any way, but to keep it quite free. The shoots are not rubbed or cleaned in any way—it would disfigure them, and they do not require it. Asparagus in a green state is only cut here for soup, &c., and for that only inferior shoots. We sometimes see observations as to the great superiority of the green-cut Asparagus over that blanched in the above manner; but they are invariably written by persons who know the ordinary green form only, or the withered blanched stalks a week old in a shop window. But those who know what good Asparagus really is—and we speak now of good judges in Covent Garden—know well that in flavour green and properly blanched Asparagus are very different things, and that the blanched is the best and most delicate. This is so much the opinion in the country where Asparagus is really well cultivated, that what is to be used for table is always grown and gathered as above described.

GREAT FLORAL EXHIBITION AT VIENNA.—It may perhaps interest some of the readers of THE GARDEN to know that the exhibition which took place the other day at Vienna was a very successful one; I venture, therefore, to send you a rough sketch of my observations made on the occasion. In the southern part of Germany Nature is comparatively rich in charms, and the tendency of social life has somewhat of an outdoor character—circumstances both adverse to the development of horticultural pursuits. I have often remarked the slow progress which horticulture made here, and therefore I was the more astonished to find the exhibition now under notice so brilliant and in every way so excellent. Not only amateur horticulturists, but also nurserymen and growers for market, all made a splendid show, which had a character peculiarly its own—a show, indeed, that nearly equalled that held last year at Brussels. The general arrangement was all that could be desired, and the rules by which its several departments were governed were well carried out; so much so,

that the special juries, as well as the general jury, discharged their several duties within the short space of half a day. The exhibition was opened by the Emperor and other members of the Royal Family. Its different departments were well supported—even a very good collection of Sarracenias, Darling-tonias, and Cephalotus was there. What are called New Holland or Australian plants were well represented, as were also Cape Heaths, and there were likewise good specimens of Himalayan Rhododendrons well flowered in a small state. Associated with these was also a brilliant specimen of Rhododendron javanicum some 3 ft. in diameter, and furnished with numerous well-developed trusses of flowers, that showed themselves off to great advantage above the ample healthy foliage. Palms, rare Ferns, and other fine-foliaged plants were capitally represented. The florists of Vienna showed that notwithstanding the difficult climate with which they have to deal and the comparative cheapness of their productions, they were capable of producing many market plants nearly as good as those seen in Covent Garden; some specialties, indeed, such as Calceolarias and Carnations, were better than I ever saw them anywhere else. Vegetables, though not numerous, were good, and among them was a fine show of Potatoes. Garden ornaments, heating apparatus, and similar exhibits were likewise well represented.—*MAX LEICHTLIN, Baden Baden.*

NEW WHITE HYDRANGEA, THOMAS HOGG.—A large basketful of this beautiful plant was shown by Messrs. Veitch & Sons, at South Kensington, on Wednesday last, when it received a first-class certificate, and excited much admiration. It is of Japanese origin, having been introduced to America by Mr. Thomas Hogg, in compliment to whom it is named; in habit it is quite as vigorous and floriferous as the common pink kind, and as the flowers are clear paper-white in colour, and are borne in immense heads, even on small plants, it is sure to become popular for decorative purposes and as a plant for market.—*B.*

BOUGAINVILLEA SPECTABILIS AT KEW.—One of the most showy plants now in bloom at Kew is a large Bougainvillea growing in the porch of the old Victoria-house. Its branches hang loosely from the iron support over which the plant was formerly trained, and are covered with thousands of bright mauve-coloured bracts, forming a profusion of wreaths and festoons from 5 ft. to 6 ft. in length. The abundant inflorescence in this case is attributed to the plant having been afforded a light sunny position, which has the effect of thoroughly ripening the young growths.—*T. S.*

TORENIA FOURNIERI.—This was one of the most pleasing of all the new plants exhibited at the show held the other day at South Kensington. It is dwarf and compact, having a more erect and branching habit than the well-known *Torenia asiatica*. The flowers are pale blue with velvety black petals, the lowermost of which has a spot of lemon-yellow in the centre. Being readily propagated and most floriferous in a small state, it will be invaluable as a warm greenhouse or conservatory plant when better known.—*J. K.*

PONTEDERIA CRASSIPES.—This singular floating aquatic plant is just now producing its pretty little purplish-blue flowers freely in one of the hot-houses in the Botanic Gardens, Regent's Park. The flowers, which are racemose, are borne on a one-leaved stem, and the plant itself is supported above the water-level by means of its funnel-shaped, buoy-like petioles, which are inflated with air. Even when not in bloom, this plant is so peculiarly interesting that it well deserves culture.—*B.*

THE DWARF BANANA.—At the meeting of the Royal Horticultural Society, held on Wednesday last, Mr. Ollerhead, gardener to Sir H. Peck, showed a magnificent dish of dwarf Bananas, or fruits of the Chinese *Musa Cavendishi*. The specimens exhibited were large and highly coloured, the smooth covering of the plump, oblong fruits being of a clear yellow tint. A cluster of this variety grown by Mr. Ollerhead and exhibited at a former meeting weighed 98 lb., a result which proves clearly that we may enjoy this, and possibly other tropical fruits, fresh from our own gardens if we desire to do so.—*B.*

CINERARIAS FOR SEED.—One of the most attractive floral displays now to be seen in London nurseries are the Cinerarias in Messrs. Hayes' establishment at Ponder's End. They occupy a span-roofed pit about 120 ft. in length and from 12 ft. to 15 ft. wide, which is now one mass of bloom. The plants on which it is produced have been selected from many thousands grown for market. To each colour is assigned a separate compartment, with the view of preventing the strain from being spoiled by means of insect fertilization. The flowers are of unusually large size, and vary in colour from the most delicate lavender to the deepest crimson. One set of plants

deserves special notice, their flowers being white and delicately tinted with mauve or lavender—colours much appreciated by bouquet makers.—S. C.

IRIS PSEUDACORUS VARIEGATA.—This variegated form of the common yellow Iris does not appear to receive so much attention as its beauty might lead one to expect. It thrives luxuriantly in any moist situation, but the proper place for it is on the margins of lakes or in small ponds. Its long sword-shaped leaves, which are beautifully striped with yellow, white, and green, are very effective when associated with green-leaved aquatic plants.—T. S.

MASDEVALLIA VEITCHI.—A small plant of this comparatively new Masdevallia, growing in the Orchid-house at Kew in a 4-in. pot, is now bearing seven large and brilliantly-coloured blossoms. Considering that this plant can be grown successfully in a cool house, and that if large plants of it are as floriferous in proportion as the one under notice, this Masdevallia cannot fail to become extensively cultivated by all who appreciate a fine display of brilliant blossoms.—J. N.

CYPRIPEDIUM NIVEUM.—Plants of this lovely variety of Lady's-slipper in Messrs. Henderson's nursery are now thickly covered with beautifully formed pure white blossoms. When grown in shallow pans and the plants covered with flowers, this *Cypripedium* is probably the most effective of the genus.—J. M.

FLOWER SHOW AT ORLEANS HOUSE, TWICKENHAM.—This is announced to take place on Friday and Saturday, the 25th and 26th of this month, and we observe that £350 are to be awarded in prizes. The subjects of exhibition are to consist of Roses, Stove and Greenhouse Plants, Orchids, Azaleas, Fine-foliaged Plants, Pelargoniums, Heaths, &c., and there is also a class for new and rare plants.

SPEKELIA OLAUCA.—Large quantities of this Jacobean Lily may now be seen in flower in the Pine-apple nursery. Though seldom met with, this plant well deserves a place among spring-flowering conservatory plants. It is easily cultivated, and when associated with Ferns and similar plants, its brilliant crimson-striped blossoms are very effective.—S.

DENDROBIUM THYRSIFLORUM.—Several plants of this distinct and attractive *Dendrobium* are now finely in bloom in the Londesborough collection. The plants, which are grown in pots, bear respectively six or seven large pendent clusters, each containing from twenty-five to thirty bright gold-coloured and pure white flowers. In habit this fine *Dendrobium* bears considerable resemblance to *D. densiflorum*, but its colours are brighter and more effective.—T. S.

SCARLET PELARGONIUMS FOR MARKET.—Three span-roofed houses of *Vesuvius Pelargoniums*, each from 120 ft. to 130 ft. in length, in Messrs. Hayes' nursery at Edmonton, are now, as may be imagined, strikingly attractive. Each house contains many thousands of plants growing in 6-in. pots. They are struck from cuttings in the autumn, and, while growing, their shoots are frequently stopped. They are now about 12 in. in height and as much through, and loaded with trusses of bloom of unusually large size. Such plants as these afford abundance of cut flowers during the winter, and in spring they find a ready sale for furnishing vases, window sills, and even flower gardens where an immediate effect is desirable.—S.

HARDY BAMBOOS SEEDING IN IRELAND.—In common with several other of your correspondents, I observed last year the remarkable fact of plants of *Arundinaria falcata* producing flowers and perfecting seed in this country, an occurrence, I believe, hitherto unknown since the introduction of the plant. I saved a small quantity of the seed, and now have a fair crop of healthy seedlings. They appear to germinate best when not covered, but merely placed on the surface of pots in a warm moist atmosphere such as a tan bed. Will the canes, which have flowered, again put forth leaves and shoots as usual, or will they die and become hard? So far, I can discover no trace of growth in the old canes.—G. PIM, *Monkstown, Co. Dublin.*

NARCISSUS POETICUS.—Several beds of this, the most beautiful of all the *Narcissi*, are now finely in bloom in Mr. Barr's grounds at Tooting. Some of the flowers measure as much as 3 in. in diameter, and are deliciously scented. It is surprising that this is not grown in private establishments more than it is, for besides producing a good effect in shrubby borders or elsewhere for a long time during the spring, the flowers are invaluable in a cut state, their pure white petals and reddish-edged cups rendering them very effective when associated in vases and epergnes with foliage and flowers of other kinds. They are greatly appreciated in Covent Garden, where they may be seen in large quantities. In the neighbourhood of Fulham they are grown by the acre for market purposes.—S.

"THE JOURNAL OF FORESTRY."—We have received the first number of a journal with this name, which deserves success for its aim as well as for the manner in which it is brought out. There is a good

list of the names of gentlemen who have promised to contribute. We should like to have seen the name of the editor as well as the contributors, believing such journals are the better for their captain's name being no secret. We fear the taste for the noble, and in all ways profitable, pursuit of forestry is not sufficiently spread among us to make this journal the success which it deserves to be.

A GARDEN AT HYÈRES.—It is not generally known that, in connexion with the "Jardin d'Acclimatation" at Paris, there exists a botanical garden, some 20 acres in extent, at Hyères, in the South of France. At the present time it contains 860 species of trees and shrubs growing in the open air, among which are 62 varieties of Oranges and Lemons, 193 of Roses, 145 of Vines, 16 of Olives, 45 of *Acacias*, 33 of *Bamboos*, and 54 of *Eucalyptus*.

ONCIDIUM MARSHALLIANUM.—A plant of this beautiful *Oncidium* in Mr. Day's collection at Tottenham is now bearing five large, branching flower-spikes, on some of which may be counted upwards of forty large, finely-spotted blossoms. Though not quite so showy as *O. Rogersi*, yet when seen in the condition in which it is to be found here, it is one of the most interesting of Orchids, and one which should find a place in every collection of them, however small.—C. S.

SIEBOLD'S DOUBLE-FLOWERED CHERRY.—This grown in the form of dwarf bushes is now very attractive in Mr. Parker's nursery at Tooting. Its flowers, which are delicately tinted with rose, are borne in dense clusters, and in great abundance. Grafted on the common wild variety, such Cherries as this may be made to assume almost any shape, and either as standards, dwarfs, or wall plants, they are strikingly effective.—C. S.

CATLEYA SKINNERI.—A specimen of this useful Orchid is now flowering profusely in Mr. Day's garden at Tottenham. It has borne eleven trusses of bloom, in some of which were no fewer than fifteen flowers of a rich carmine colour. Many of them have been used in a cut state for indoor decoration, a purpose for which they are very valuable, lasting, as they do, in water for a considerable time. Plants that can be brought to such perfection as the one in question cannot be too highly prized.—C. E.

A GARDEN IN DRURY LANE.—I have just seen a piece of work completed by Mr. Weston, which I think should not be lost sight of. It is a movement in the right direction, and if matters of a similar kind were to become a little more general in London, we might claim some day to equal Paris. An old churchyard in Drury Lane—I dare say many have noticed it, having rather a pretentious front for the neighbourhood, a mortuary on the one side of the entrance, and a cottage on the other, while the churchyard formed a playground for the cats—has just been laid out and planted; the space, which would be Grass under ordinary circumstances, is gravel; the paths are asphalted, and the whole place has a comfortable look, and is furnished with a good supply of seats. The "Times" in alluding to this matter, says:—Some of the old tomb-stones have been preserved at the sides, but the main area has been broken up and laid out in flower-beds with a Weeping Elm in the centre and trees and shrubs round the sides. *Michaelmas Daisies*, *Heartsease*, and *Wallflowers* occupy the beds, and the people who visit the garden will be put upon their honour to leave them there. It does not appear that any famous persons are recorded to lie in the graveyard now put to such a good use. Nell Gwynne and Roubillac, the sculptor, were buried within the precincts of the church itself, now represented by the famous work of the architect Gibbs at the corner of Trafalgar Square. Charles Dibdin was interred in the other burial ground belonging to the church at Camden Town. The case is thus very different from that of the Friends' historical burying ground in Bunhill Row, which Miss Hill has tried to have also preserved as an open space. At present this site, dear to Nonconformists and in the midst of a crowded neighbourhood, seems likely to be built upon. The Rev. W. G. Hamphry, the vicar of St. Martin's, on Tuesday, in the name of the Vestry, declared the garden open, and congratulated all upon its being rescued from weeds and prowling cats. He expressed a hope that the neighbouring parishes would contribute to the cost of maintenance. Mr. Shaw Lefevre, M.P., chairman of the Commons and Open Spaces Preservation Society, followed, proposing a vote of thanks to Miss Octavia Hill and the Vestry of St. Martin's for the part they have taken in the matter. He alluded to what had been done in other London parishes—by the Rev. W. Rogers in Bishopsgate, by the Rev. Harry Jones in St. George's-in-the-East, and in the churchyard of St. John's, Waterloo Road, to make the burial places, which once spread disease around, sightly and wholesome. Mr. Thomas Hughes seconded the vote. He said that in that immediate neighbourhood there was the finest garden in London, the garden of Lincoln's Inn Fields; it was used by scarcely any one, and that should be thrown open too.—PETER BARR.

LILACS.

THE Lilacs are now in full beauty in Paris, and form at present the principal attraction of the gardens there. The bushes are pruned closely for two reasons—to insure a strong bloom, and to keep them about the same size every year. They are in lines, as a rule, like soldiers, only more regular. With us this lovely shrub is often left to perish and starve from overcrowding. It is something to even train a common shrub; for so much we have to be grateful in Paris, where the State gardens are virtually in the hands of architects, engineers, and other persons who know little about gardening, and have no sympathy with right efforts therein. The true way to grow Lilacs is not that used in Paris. One ought, perhaps, to apologise for wasting words about a subject that apparently never has excited the least attention. The right method would be to group them naturally on the Grass, or on mounds or slopes, allowing each bush room enough for its full development, that is to say, it should not be starved above or below ground; it should not be tortured into anything like a broomstick and balloon-head as in Paris, or contorted by neglect as with us. It should be allowed to assume a natural form, and be pruned, so that form is never interfered with; moderate thinning of the branches to secure a vigorous bloom would be desirable. There are now so many fine varieties of Lilac that varied and most beautiful small groups or groves could be formed of them alone. To have a Lilac group, or several, or a small grove, or even a few thoroughly well-grown specimens, would be infinitely better than the common plan of scattering a number of plants through the shrubberies to dwindle or to perish.

EARLY PRUNING OF TREES AND SHRUBS.

THE pruning knife is a useful implement, but it should not be used indiscriminately, as it would be better to have trees and shrubs less perfect in outline than to have them slashed and hacked about unskillfully; but there is scarcely a tree planted that would not be improved by a little aid from the knife during the first ten or twelve years of its existence, provided it be done at the right time and in the right manner. The best time to prune Evergreens is just when they are commencing to grow, as then the wounds quickly heal. April is the most suitable month for all that are non-resinous; the pruning of the resinous kinds should be deferred till later. Where large breadths of common Laurels are used for covering banks or are grown in masses for undergrowth, and where, as a matter of course, to keep them in good condition, they must be pruned annually, the pruning is and may be done any time during open weather in the winter, not because that is the best time, but simply from the impossibility of getting through such work where much of it has to be done if it were delayed till spring; besides, when they are cut in closely every year, the growth becomes so dense and carpet-like that the cold, unless very severe, does not penetrate sufficiently to injure them; but where from neglect and otherwise it is necessary to cut off large branches or to head them down, then the pruning should be delayed till spring. All spiral-growing shrubs, such as the Arbor-vita, Irish Yew, Junipers, &c., whose beauty mainly consists in perfect symmetry and exactness of training, should be carefully and judiciously pruned. Without this attention they become unwieldy in size, and are liable to be blown about and injured by wind. But in pruning no evidence should be left of the operation beyond the improved outline imparted to them. If long cuts be visible, then the work has been recklessly performed. Every projecting branch that it may be necessary to remove should be cut back to its junction with another nearer the trunk of the tree, making the cut short and clean. In the management of handsome specimen trees, or of those that are intended to form such specimens, the amount of pruning actually required will be small if taken in time. Even all pruning of forest trees should be done before the branches that may require amputation become large. Pruning trees severely that have long been neglected is an operation of very doubtful utility if sound timber be the object, for, wherever a large branch has been removed, decay will be found in the wood when sawn up—but this fact need not preclude attention being given to balancing the head and removing rival leaders

When a tree is young is the time for pruning it and for securing a proper foundation for handsome proportions; if not done then, the most assiduous attention afterwards will not mend matters, and may do positive harm. All deciduous trees are usually pruned in winter when the leaves are off, but flowering shrubs, such as Lilacs, Ribes, &c., are best pruned after the flowering is over. By removing annually the longest branches, there is always a continual succession of young wood coming up to replace that removed, and, therefore, there is never any dearth of flowers. Treated in this way large shrubs may remain in good condition many years. Standard Thorns form very handsome objects grouped or scattered about a lawn or park, and if the long, strong branches be shortened back for the first eight or ten years, they form beautiful weeping heads, far superior to anything I have ever seen when left unpruned.

E. HOBDAV.

Trees on which Mistletoe Grows.—In the remarks made lately on Mistletoe, I have not seen it noted as growing on the Azalea and Nut tree. At Eridge Castle, near Tunbridge Wells, there is a specimen of it on the former, and in the verger's garden at Southwell, it grows on the latter. This month a very interesting trip might be made to see the Mistletoe on all the deciduous trees and shrubs whose stations are known. I have still a vivid recollection of a wild-geese walk, which I took above twenty years ago, in search of the Oak at Eastnor Castle (near Ledbury), when the leaves were fully out. Of course at such a season the search was fruitless. Here in Scotland the only trees upon which Mistletoe has been as yet grown, are Apples, Thorns, Mountain Ashes, Pears, Limes, Almonds, and in the Botanic Garden, Edinburgh, there is a fine specimen on an American Oak; also on black Poplar, and Mes-pilus. Gordon Castle is, I believe, the farthest place north at which it grows, although Keith Hall, Aberdeenshire, is probably both higher and colder; there it may be seen on the Mountain Ash. Berries grown at Hermiston House, in the neighbourhood of Edinburgh, germinated on trees in Wigtonshire, when fruit from Herefordshire failed. I am of opinion that failure oftener occurs through smearing unripe berries in situations in which they are intended to grow than from any other cause. A covering of muslin over the seeds here served to attract the inquisitive sparrows; so I discarded that plan, and now I smear the fruit on the under side of a young branch.—F. J. HOPE, *Wardie Lodge*.

Flowers in Hospitals.—With the return of spring, our hospitals begin to look gay with flowers, and, according to the "Lancet," there is scarcely a ward to be found which is not decorated with its quota of Primroses and Hyacinths. Do those who so thoughtfully send these beautiful things from the bright country into the sick wards of our dusky town ever think how their presents are displayed? The "putting up" of flowers is an art which hospital nurses are very often little skilled in, and between a lack of talent or of time, and a want of suitable vessels, the flowers are often not shown to the best advantage. Wallflowers tightly jammed into a half-pint mug scarcely look their best, and a common washing-basin is hardly a suitable vessel for the display of Primroses. But what is to be done if no proper flower-vases are to be had? No hospital committee would feel justified in spending money on such trifles, and no one seems ever to think of making such a present, which would be most acceptable to a hospital. In the present day when the fashion in table decorations changes every season, one would suppose that disused and obsolete flower-stands are to be found in almost every glass or china closet, and we feel sure we have only to make this little want of our hospitals known to ensure its being speedily satisfied.

The Spanish Onion at Home.—In the April number of the "New Quarterly," Mr. John Latouche thus describes the culture of Spanish or Portuguese Onions now so largely imported to Covent Garden, and other vegetable markets in this country:—"Oporto is the chief port of exportation for the large variety of Onion which is known in trade as the Spanish or Portugal Onion. Its cultivation is as follows:—In the month of October the seed is sown in a sheltered spot in very well manured seed beds. In about ten days the plants appear, are watered in dry weather, weeded, and the surface occasionally stirred with a sharp-pointed stick. The young plants, not subjected to any severe frost, for the thermometer very seldom falls below 35° of Fahrenheit, enjoy an uninterrupted growth till springtime. In March they are taken up, being then some 5 in. to 8 in. in height, and planted from 9 in. to 12 in. apart, in furrows made by the hoe in well-ploughed and harrowed land. The furrows are filled to the depth of 3 in. or 4 in. with well-rotted manure, with which the roots of the young plants are placed in actual contact. A very essential condition of the successful cultivation of the Onion is water. The abundant and timely irrigation

of the growing crop requires great and constant care. After transplanting, the crop has two or more hoeings and weedings. With the last weeding are sown either White Turnips, Maize, or more rarely, Grass seeds. The Onion crop is off the ground in August, and sometimes in July."

Influence of Time of Pruning Pear Trees on Season of Blooming.—I have read Mr. Fish's communication on this subject (see p. 329) carefully, but I find nothing in it to strengthen the views which he had already expressed. He goes into a long physiological disquisition upon the action of the sap and vital forces connected with vegetable life generally. But I may remind Mr. Fish that conclusions based on nothing stronger than analogy drawn from plants different in their habit and nature from those under consideration are wholly outside the question, and have not the slightest weight in supporting his views. The subject under discussion lies within very narrow limits. Mr. Fish says that the time of blooming in Pear Trees is accelerated by early pruning. I say that so far as my own experience and observation go, it is not, and I have given numerous instances supporting my opinion, and I could give many more if necessary. The proof of his assertions rests with himself, and so far he has failed to furnish them. We have now-a-days too much theory connected with horticulture, that is not only unsupported by facts, but totally at variance with the results arrived at by actual practice. Mr. Fish tries to turn the strong confirmatory evidence in support of my views afforded by the storm-dismantled tree to favour his own, and although he envelops the plain facts of the case in a cloud of assumed possibilities which may mislead those who are not acquainted with the subject, they are not likely to have any weight with those who have a practical knowledge of fruit culture.—T. BAINES.

Vine Growing without "Steaming."—As I have grown Vines for many years on the principle that your correspondent condemns (see p. 292), viz., syringing and steaming, I should be glad to know how the ravages of red spider are to be prevented if water be not used? I have been told that a humid atmosphere is death to it, and I have found when I stop syringing and have a dry atmosphere in order to colour the fruit, red spider makes its appearance.—NEMO. [When I condemned "shutting up and steaming the house with moisture," I did not mean it to be inferred that the use of the syringe was to be discontinued when required, but only that a prolonged vapour-bath was ungenial to the Vine. If "Nemo" treat his Vines on the "principle that I condemn," and finds, when he stops syringing at the colouring period, that they are attacked by spider, he need not be surprised. But let him begin at the beginning by giving his Vines plenty of air at all times, and less of the steaming treatment, &c., and he will find the foliage produced to be of a different and more beating texture, and not liable to be attacked by insects—something, indeed, like the foliage of Vines grown out-of-doors, where they are never seriously attacked by spider, so far as I am aware, either in this country or in the Vine-growing countries on the Continent. The vapour-bath treatment produces weakly foliage, which cannot resist even a natural degree of dryness, and it soon falls a prey to insects.—C.]

Conditions Affecting the Growth of Timber.—In my opinion if landowners would plant the same quantity of trees on two acres which they now plant on one it would pay them better, especially if the land were well trenched before the trees were planted. Where there is a deep alluvial soil, the trees may be planted thicker than on poor land; but, for a profitable speculation, the question is, which is the best kind of timber to plant on the different kinds of soils? We know, as a rule, that the Oak grows best on the old sandstone formation, Larch on the new red sandstone, and Ash and Beech on the limestone. Spruce and Scotch Fir will grow well on most soils except mud; and the Silver Fir grows best on sand or on a gravelly subsoil. Much of the wood that is now planted is for game covert, and, being planted thickly, it makes a good covert for a few years; then the lower branches die off, and we have no covert. If Larch and Spruce were planted, then the ends of the lower branches would touch the ground, and make a good covert for years.—G. F. B.

Botryanthus (Muscari) Gussoni (Todaro)—Through the kindness of M. Max Leichtlin I have lately bloomed this little-known species. It has long, rather broad leaves, recurved, and appearing late in the autumn. The flower-buds begin to show themselves at Christmas, but do not expand till March. The raceme consists of a few large purple-blue flowers shaded with white. It comes nearest to *M. commutatum*; indeed, Mr. Baker thinks they are identical; but with me *M. commutatum* exhibits differences in habit, growth, and time of flowering, which lead me to think that it is distinct.—H. HARPER CREWE.

Paraffin-oil-coated Seeds v. Birds and Mice.—It has been stated in a contemporary that seeds dipped in paraffin oil would not be touched by birds or mice. As this seemed a simple preventive, before sowing my Salady seeds three days ago I rubbed them over with this oil as directed, and I find that many of the seeds have, nevertheless, been eaten by mice. It is therefore evident that this oil-cure is useless.—A NORTHERN GARDENER.

THE GREAT FLOWER-PAINTERS.

JEAN VAN HUYSUM—BORN 1682, DIED 1749.

THE artists of Holland were the first to treat the art of flower-painting in a truly naturalistic spirit. In the art schools of France, Germany, and Italy, flower-painting had, it is true, been skilfully practised, but almost exclusively from a simply decorative point of view. Graceful grouping, fluent pencilling, and harmonious colouring had been brought to great perfection by many of the artists of these countries, but always with a view to a subsidiary art, as an agreeable adjunct to some other work which was always principal, while the flower feature was quite secondary; for instance, as an adjunct to the foreground of a picture, as an enrichment in the coloured decorations of monumental architecture, or as a pleasing feature in the ornamentation of panels, walls, or ceilings of apartments. Dutch artists, on the other hand, influenced no doubt by an intense love of gardening, painted flowers for their own sake, for their colour-beauty, and for their natural graces. It was from Dutch gardens that the glorious old Cabbage Rose was first sent into European markets; and it may have been the combination of its rich perfume with the luxuriant mass of beautiful petals culminating in a crowded centre of which deepens in colour to a glowing carmine, that decided the younger Van Huysum to become a flower painter, and, *par excellence*, a painter of Roses. His father, Juste Van Huysum, was an art-manufacturer well known for his refined taste as regarded all kinds of garden decorations, from delicate trellis work to the higher classes of garden ornament represented by stone or marble vases more or less enriched with sculpture, which frequently reached a high standard of art. These objects, to the contemplation and study of which Van Huysum had been accustomed from childhood, were frequently introduced in his subsequent pictures, for the composition and painting of which he threw up all interest in his father's more profitable enterprises. His treatment of floral compositions, which soon acquired for him an European reputation, was founded on a pure worship of Nature. He never tried to superadd a grace of his own. Previous flower-painters had often, in their almost strictly decorative treatment, adopted an arrangement akin to positive uniformity—the arrangement of their groups having, as it were, a centre, and two wings. Then came an arrangement founded on a kind of symmetry of a higher kind, in which parts *balanced* each other, rather than being forced into an almost mechanical correspondence of form and dimensions. Van Huysum entirely threw over all these conventionalisms, to which, as in the subject here represented, he opposed randomly massed profuse groups of gorgeous flowers, just as they came to hand, fresh gathered in the early morning, with the dewdrops still upon them. In our first illustration the magnificent group has evidently fallen together with a wild profusion and natural grace which the artist did not seek to trim, and balance, and guide, but to reproduce purely and simply, and free from any of the fancied elegancies of mere art. On the pedestal it lies, just as it may have fallen, when the rest of the beautiful mass was thrust reverently, without trimming or sorting, into the richly sculptured marble vase. In the mass of beauty which this picture presents, and which is not a "composition," but a natural falling into place of a mass of flowers, we have rich selections of the garden favourites of the time. First, the grand Rose, at that time the new glory of the gardens; then, other specimens of the same flower, contrasted with the best of the white Roses then known; and which is still to be found in many old-fashioned gardens; then we have an audacious but splendid double Poppy towering above the rest of the group, and lower down Anemones, Irises, Centaureas, and, conspicuously, a bunch of Auricula, treated as none have treated that flower since Van Huysum. It was a favourite flower of the Dutch cultivators, and specimens are to be found among the truthful representations of Van Huysum, which even modern culture, with all its recent successes in the development of that genus, has not yet surpassed. The fame of Van Huysum reached England before his mid-career; and Sir Robert Walpole commissioned him to paint two pictures in his most elaborate style. Our first example, just described, is probably one of them, as it was exquisitely reproduced by our own great mezzotint engraver

Poppies, Roses, Anemones, Auriculas, Convolvuluses, Tropæolums, Campanulas, &c.

(After VAN HURSTUM).

Earlom, whose work is an acknowledged masterpiece of the art, and immeasurably finer than the clever and very beautiful cut, on a reduced scale, which we are enabled to present to our readers. A second smaller group (see p. 351), consisting mostly of Roses, Anemones, Larkspurs, and Carnations, exhibits a similar grace and *abundant* of treatment. It will be noticed that insects, birds' nests, and other beautiful objects associated with gardens, were lovingly treated by the delicate pencil of this exquisite painter; indeed, his birds' nests with eggs have never since been approached in elaborate beauty of treatment, till the time of our late lamented artist Hunt, and his more or less successful followers.

H. N. H.

THE INDOOR GARDEN.

CHINESE PRIMULAS AND THEIR CULTURE.

The great improvement which these have undergone within the last few years, and the freedom with which they produce their flowers at a season when there is little else to render plant structures attractive, make them general favourites, and those who would have them early in bloom and in first-rate condition, should lose no time in sowing the seed. This should be done in pans of finely sifted, light, rich soil, pressed down moderately firm, and then watered, and allowed to stand a few hours to drain. Many seeds are lost or fail to germinate through inattention to this, as they are either washed bare, or become so sodden as to cause them to rot. In recommending the use of light soil for such choice and delicate seed as that of this Primrose, it should be generally understood that it must have sufficient cohesion not to lie loose and hollow, else the air would pass so rapidly through it as to carry away the moisture; and if the seed germinated at all, the plants would stand but little chance of making headway, on account of their inability to get proper root-hold. In raising seedling Primulas the first step is to well drain the pots or pans in which the seed is to be sown. This done, the next thing is to add a sufficient amount of soil, which should consist principally of leaf-mould, loam, and peat, in the proportion of two-thirds of the leaf-mould and peat to one of loam, so as to fill the pots or pans about half full, and then to finish off within an inch of the top with the same kind of material finely sifted, during which process the whole should be regularly pressed down in order that the seed may have a firm bed. The soil ought then to be watered with a fine-rosed watering pot, and allowed to drain for a few hours, when it will be in proper order for sowing. This should be done by scattering the seeds thinly and regularly over the surface, into which they may be slightly pressed, and then covered over with very fine peat and sand, the latter rather preponderating, so as to give weight and prevent the air reaching the seed too readily. I prefer this plan of treating all choice seeds to that of having such a loose, gritty soil under them, as is so often practised, and which is, in nine cases out of ten, the cause of failure.

Seed Sowing and Subsequent Treatment.

Next to having suitable soil, the most important thing in raising young Primulas, or, indeed, any other plants, from seed, is to maintain the latter in a uniform medium state of moisture, an end which may be best accomplished by laying a piece of glass on the top of the pot or pan, and on that some Moss or thick brown paper to shut out the sun and light till the seed germinates, when the young plants must be placed near the glass to keep them dwarf and stocky, and prevent them from drawing. A Melon or Cucumber bed, or any hotbed frame, is a suitable place for them, the moist, genial atmosphere of which suits them far better than any house, on account of the uniformity there always is in the humidity and heat arising from manure beds. Primulas, being shade-loving plants, should be screened from the sun by a thin piece of canvas, and nursed on close to the glass till ready for pricking out. This should be done, as soon as they are large enough to handle, in fibry peat beaten up fine and mixed with a little loam, or in some thoroughly decomposed leaf-soil that has been passed through a sieve, to which about one-third loam and a little dry, flaky cow manure, well broken up, should be

added. In this mixture they will soon make a fresh start, and grow vigorously if placed in any hotbed frame, or house where they can enjoy a temperature ranging from 55° to 75°, with a moist atmosphere and sufficient air, according to the state of the weather. If allowed to remain too long together after being pricked out, they quickly become drawn, and this should be avoided by timely potting in 3-in. pots, using the same kind of soil for the purpose as recommended for the earlier stages of growth. After potting, they should be returned to some close pit or frame, or set on the shelves of a house, where they can get a little moist heat and shade during bright sunshine, until they again get a start, when by the middle of June they may be placed in their summer quarters. The best receptacle that could be provided for them at that season is an ordinary garden frame, so placed as to be partially shaded by some tall tree or building, so that the sun does not get at the plants during the heat of the day, and this will be found far better than resorting to mats or other appliances that not only keep off the sun, but obstruct the light at the same time, and thus cause the plants to be weak and drawn instead of having that stout, sturdy habit which they always possess when grown under favourable conditions. Another objection to artificial shades in cultivating Primulas is, that they are seldom on when most wanted, or remain too long over them in the afternoon; whereas, if the frame be so placed as not to require their use, much unnecessary labour is done away with, and there is no risk of injury happening from inattention. The floor of the frame should be rendered hard and impervious to worms by spreading over it a good coat of coal ashes, rammed hard down after being watered, on which to set the plants, and the distance of these should be about 1 ft. from the glass, which will be quite near enough during summer weather. Their treatment during that season will consist in supplying them properly with water, of which they require liberal supplies, and in keeping them damped overhead every afternoon, so as to maintain a humid atmosphere round them, with a cool, damp bottom for the pots to stand on, which is a very important matter in the successful cultivation of Primulas. As soon as they have become well rooted, they should receive their final shift into 6-in. pots, using the same kind of soil as before; and in order to keep the plants erect and steady, it will then be necessary to insert three small sticks around each, placing them triangularly close up to their stems, and about an inch or so above the soil, in which way they will afford perfect support. By the end of September it will be time to remove them to their winter quarters, for if allowed to remain longer in the frame, the damp would cause their lower leaves to turn yellow, and spoil the beauty of the plants, as they never again recover their healthy appearance. A light airy shelf near the glass is the most suitable situation to keep them during their period of flowering, as their blooms become much brighter and stouter than they do farther away from the light, where damp is likewise sure to affect them. The temperature of the house in which they are placed should never fall below 45°, nor be more than 10° above that during the day by artificial means, as a warm, dry atmosphere, ranging, as regards heat, anywhere between those two points, will suit them perfectly. In watering, great care should be exercised not to wet the crowns of the plants, as the water lodges at the axils of the leaves and engenders canker, a disease to which Primulas are rather subject during the winter season if kept too wet or in a low temperature. Clear liquid manure—such as may be made from cow or sheep droppings, or the drainings of the farmyard—is of great assistance while the plants are producing their bloom, when it should be used freely in a properly diluted state; and, if a little soot be added at the time of making the manure water, the plants will be much benefited in colour and healthy appearance, as soot is a stimulant that always shows itself in a very marked manner whenever applied.

Seed Saving.

In order to maintain a first-class strain, annual selections of the best should be made for the purpose of seed saving, to produce which in a free manner the plants must be set in a warm dry house close up to the glass, where they can get

plenty of sun and air to ripen and disperse the pollen. Thus situated, there will be no difficulty in obtaining plenty of seed without the aid of artificial fertilisation, to which many resort when desirous of rendering them as profitable as possible. Fortunately, there are now many semi-double varieties that seed almost as freely as the single kinds, and this is a great boon to amateur cultivators, on account of the difficulty there is in propagating double kinds, which have to be done by means of cuttings, and which require some considerable skill and attention. The present is the best time of year to set about the operation, and the proper mode of procedure is to divide the plants with a sharp knife, securing to each separate piece as large a portion of the thick fleshy stem as can be got, and with as many roots attached as possible. This done they should then be trimmed of any dead or decaying leaves or leaf-stalks, and potted in sandy peat and leaf-mould in small pots and afterwards placed under hand-lights, where they can be kept close and warm till rooted. The stove or any forcing house is just the place for the purpose, and, to prevent the soil drying, it is a good plan to plunge the pots in damp Moss or Cocoa-nut fibre, as no water must be given till they have callused and begun to form fresh roots. In potting the cuttings the best way is to fill the pots loosely, and then to thrust a finger into the soil to make a hole sufficiently large to receive the base of the cutting, which should be inserted up to the lower leaves, and then filled round with pure, sharp silver sand, which will absorb any moisture at the cut part, and prevent it from damping. All that is necessary while they are under the protection of the hand-lights is to shade from bright sun, and, should the leaves flag severely, to give a bedewing over them, but not sufficient to run and wet the soil around them. When rooted they may at once be shifted into 5-in. or 6-in. pots, in the same kind of soil as recommended for the single-flowered varieties, and be treated in all respects during the summer in like manner. Being somewhat more tender than they are, a few degrees more heat are requisite during the winter, but, as *Primulas* are impatient of a close confined atmosphere, air should be admitted on all favourable occasions.

S. J.

POINSETTIAS SINGLE AND DOUBLE.

ALTHOUGH the new double *Poinsettia* has done well in many places, and notably so with the firm who first brought it into notice, its propagation has been pushed so hard to meet the demand and get up stock, that up to the present time it has scarcely had a chance of showing its true character; therefore, grand as it is, it may yet surpass all the anticipations that have been formed respecting it. Some object to *Poinsettias* having such lanky stems: but this only occurs when they are improperly treated, either by being started too soon, or having more heat than they require. In the former case they get drawn up before there is sufficient sun and light to harden and consolidate their growth, which, in plants that are naturally of a somewhat soft character, is generally rapid. For certain purposes, however, tall plants are very desirable, as, for instance, to overtop others, so as to produce variety, a purpose for which *Poinsettias* are specially adapted, affording as they do in such positions a character and individuality quite unattainable by plants of other kinds. During last winter I had them in use among a general collection of greenhouse plants, above which they stood out clearly at a height varying from 1 ft. to 1½ ft., and as they were associated with the white-flowered *Richardia æthiopica* and *Chrysanthemums* of a light colour, some idea may be formed of the effect which they produced. When required for purposes of this kind, single-stemmed plants are best, as they can be dotted about without interfering with anything beneath them or producing too great a mass of colour in one place. Those who have hitherto treated them as stove plants, may be surprised to find them spoken of as being used in a greenhouse; but if they be kept as dry at the root as they will bear without flagging, and the temperature is never allowed to fall below 50°, they will stand without suffering in the least, provided the atmosphere be kept thoroughly dry and the plants are so situated as to be out of the reach of draughts or cold currents of air. If they can be accommodated

in this way there need be no hesitation in using them in such structures, but in all cases before being removed they should be gradually inured to the change, in order that the variation in temperature may be brought about by degrees, instead of a sudden transition that chills both root and top at the same time, and paralyses the whole energies of any plant subjected to such treatment. Although *Poinsettias* are fond of bottom-heat, and bear larger and finer-coloured leaf-bracts when they have such stimulus afforded them, they are more impatient of change afterwards, and never endure cold so well as they do when grown without its use. This being the case, it is therefore advisable to simply set the pots on the stage in any cool stove when taken in from cold frames in autumn. In doing this they should be so placed as to have the heads of the plants within a few inches of the glass, that they may have the benefit of all the light possible in order to get the leaves of a stout, thick texture, and their colour as bright as they are capable of attaining. The difference not only in these, but in all other flowers when treated as above, is surprising in regard to the time during which they will last, either in the cut state or on the plants, as compared with those that are grown under less favourable circumstances.

Culture.

As *Poinsettias* are required for various purposes and of different sizes, they should be started and propagated a few at a time, at intervals of a month or so from now to the middle of July, as by so doing they may be had ranging from 1 yard in height down to 1 ft. or less, with heads of floral leaves in proportion to the size and strength of the plants. These may be grown with either single stems or several, so as to form large masses of colour, but in the latter case it is necessary to cut back such as flowered last year, leaving a bud or two at the base of each, which will break and make strong shoots almost equal to any that are struck from cuttings or eyes at the present time. Premising that the plants are now dry and at rest, stowed away on the back stage of the stove, the proper course will be to take a portion of them and head them back, saving the tops so removed for cuttings. The plants ought then to be placed where they can get a brisk heat in which to start them, and as soon as that takes place they should be shaken out of the old soil and re-potted in smaller pots, with the view of giving them another shift later in the season. This done they should be plunged in a gentle bottom-heat for a week or so, in order to assist them in forming fresh roots; after that they should be accommodated in some light airy position near the glass, such as a shelf would afford, where they can be syringed and have a temperature ranging from 60° to 70°. Managed in this way the growth which they make will be stocky and short-jointed, and altogether of a more satisfactory character than any which they make when placed on a stage overshadowed by other plants, as is frequently the case. The soil best suited for *Poinsettias* is a compost consisting of about equal parts peat and loam with just sufficient sand to keep it open and porous, for though they require copious supplies of water during summer, they dislike stagnant moisture or any approach to it at any time; neither will they bear a dry atmosphere, and therefore both must be guarded against, or the leaves will inevitably turn yellow and fall off, or become so infested with red spider as to be greatly disfigured, thereby spoiling the beauty of the plant. During June, July, August, and September, the best place for them is a cold pit where they can be set on a hard floor of ashes impervious to worms. In a position of this description they are more under control, and far better circumstanced than they would be if kept along with the usual occupants of the stove, most of which require shade, while *Poinsettias* are benefited by exposure to the full rays of the sun, except perhaps for an hour or so during the hottest part of the day, when the thinnest of shades, such as a piece of hexagon net may be thrown over them; this is, however, only necessary in cases where the glass is of an inferior kind. By closing early after a good syringing, much of the solar heat may be conserved for the night, and a genial moist atmosphere maintained, which will keep the plants in luxuriant health and free from red spider, which is ever ready to attack them, and can only be warded off by steadily pursuing the course of treatment just

indicated during the whole of the summer. In order to prevent any rapid drying of the soil, which generally takes place when the pots are exposed, it is a good plan to have some loose littery matter, such as a few leaves, straw, or bracken, or anything of that kind scattered around them, so as to afford shade without lying sufficiently close to obstruct the air, which any other close plunging material would do to the detriment of the roots. Towards the end of September, when the nights begin to get chilly and cold, the plants must be moved to warmer quarters, in order to assist them in developing their coloured leaf-bracts, in which they may be greatly aided by the use of clear, weak liquid manure whenever they require water, a practice that is far better than using manurial matter in the soil, as then they get it long before it is needed, and being thus stimulated a gross growth is the result; and when this takes place, it is scarcely satisfactory so far as flowers are concerned.

Propagation.

Poinsettias admit of being propagated in a variety of ways, such as by means of single eyes, cuttings made of the hard ripened wood, or any of the short young shoots taken off with a heel. The latter are the best for forming small dwarf plants for table decoration and similar uses, and may be taken off any time from now to the middle of July, according to the size and height required. With a brisk bottom-heat of from 80° to 90° and a close, moist atmosphere, with proper shade, they will root readily, and may then be potted on and treated as recommended in the case of old plants. In making cuttings from last year's wood, the firmest and best should be chosen and divided into lengths of about 3 in. each, of which pieces should be so cut as to have a bud or joint both at the base and top. If these be then inserted around the edge of a pot in sharp, sandy soil, and nearly buried to the tips in the same, and then plunged in heat, as mentioned above, scarcely one will fail. Single eyes are treated much after the manner of those of Vines, and only differ from cuttings in the way in which they are made, and in having one joint or bud instead of more; but except in cases where it is desired to make the most of every piece of wood and increase stock to the utmost extent, cuttings are the best and more to be depended on than eyes for rooting. In propagating from eyes, about $\frac{1}{2}$ in. of wood should be left above and below the buds, and each piece should then be laid with the eye uppermost in prepared pans or pots of sandy soil so as to be slightly covered over, after which a gentle watering and brisk heat will soon start them into growth. S. J.

Draining Cutting-pots.—Mr. Plimley, of Acton, who grows plants very successfully for market, showed me the other day a plan of draining cutting-pots which is not often adopted elsewhere. Instead of crocking them in the ordinary way, Mr. Plimley uses inverted flower-pots of as large a size as the pots for the cuttings will admit, and over the hole is placed a small piece of crock to prevent the soil from falling through. When the cuttings are inserted in the pots they are placed on a slate stage, under which there is a hot-water tank, and are covered up to the rim with Cocoa-nut fibre; the heat then passes up the centre of the inverted flower-pot as well as round the sides of the cutting-pots, and thus the soil is warmed equally, and the cuttings root regularly, and are all struck and fit for potting off at the same time. Soft-wooded plants, such as Carnations, Verbenas, Fuchsias, &c., are struck in this way in four or five days.—W. S.

Pentas carnea.—Few plants are more easy of cultivation than this, and few among our stove and greenhouse plants better repay the little trouble they require to bring them to a state of perfection, yet in private establishments good examples of it are seldom found. Cuttings of the young wood will strike readily at all seasons of the year, and under liberal treatment will in a very short time furnish neat and floriferous plants. Its chief value, however, consists in its being capable of being brought into bloom as easily during the dull months of winter as at other times of the year; all that is required is to keep the shoots regularly stopped so as to induce the plants to grow bushy, and, if this be discontinued in the autumn, nearly every point will produce a good head of delicate pink and white blossoms during the winter. In a cut state the blooms are very effective and valuable, and after one crop of flowers has been cut, the plants will, if kept clean and well watered, soon throw out shoots that will fur-

nish another supply. Plants of this *Pentas* are now blooming freely in Messrs. Rollisson's nursery, in which state they have been all through the winter.—S.

Raising Alpine Auriculas from Seed.—These are easily raised from seed, and if we persevere in saving seeds only from our best flowers, we shall in time get together a most interesting collection. This is a good time to sow the seeds, and it is better, in order to guard against accidents, to sow in pots or pans, which should be well drained, and the soil should be rather sandy. Do not cover the seeds too deeply, and place a thin layer of Moss over the surface of the soil to keep it moist and so encourage germination. When they come up and require more space they may be pricked off into other pans, or be planted out in a prepared bed in a shady border. They will all flower the next spring, and they are very interesting subjects to have in pots at this season when in flower for decorating a cool house. They are everybody's plants, as they are neither expensive to raise nor to keep.—E. HOBDAV.

Gardenias Planted out v. Pots.—During the past few years many growers of Gardenias in private establishments as well as market gardeners, have planted them out, with the view of obtaining more cut bloom from them than can be got from plants in pots. I have, however, been lately informed by several cultivators of Gardenias for market, that when grown well in pots more profitable results can be obtained than when planted out, inasmuch as the plants can be brought into bloom at whatever time they are most required, and the flowers from good pot plants are more perfect in form than those from bushes planted out. Another advantage in having them in pots is that in the event of the house being required for any other purpose, the plants can be quickly removed. For furnishing a wall or as permanent plants in a conservatory, a few Gardenias planted out answer well, but those who grow them for the sake of their blooms in a cut state will probably make a mistake if they plant them out. Gardenias are liable to be attacked by mealy bug, which may be effectually eradicated by dusting them all over with soot, with which has been mixed a little guano. The foliage of the plants should be perfectly dry, and care taken to dust the mixture into every little crevice. In this state they may remain for a few days, when the foliage should be thoroughly washed by means of a syringe. If done before the plants commence to make young leaves, there will be little danger of their sustaining any injury.—C. S.

Primula amœna alba.—Mr. Harris (see p. 329) has probably got only the common *Primula cortusoides* alba, and not the true *amœna* alba. The flowers of the latter are large, perfectly white, and devoid of any green stripe, but they are unfortunately both flaccid and pendent, and therefore not so showy as the erect forms of *amœna*; it is not quite so robust as either *P. amœna*, *hiscina*, or *grandiflora*, but nevertheless it is easily grown, and, under ordinary care and cultivation, flowers freely. Some of the newer forms, such as *P. maxima*, *corules alba*, *laciniata*, &c., will be found to be decided improvements in habit on *P. amœna* alba, having stout, erect stems, and flowers large in size, and facing the observer boldly. It is not difficult to produce good heads of bloom. When the plants are out of flower, turn them out under a shady fence or into a cold frame for the summer, and in the autumn knock the balls of soil out of the pots, free the roots entirely from it, and, selecting the strongest crowns, plant three into a 4½-in. pot or six into a 8½-in. pot. The weaker crowns may then be planted more thickly, and should some of these not flower, they will at least make strong-blooming crowns for the ensuing year.—A. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Centaureas from Seed.—*Centaurea candidissima* is extensively used for the summer decoration of the flower garden, and when any difficulty is experienced in raising cuttings, as is often the case, I would recommend it to be raised from seeds early in spring. If they be sown thinly in well-drained pans filled with light, fine soil, and slightly covered and placed in a gentle heat in January or February, they will soon germinate; and if the young plants be pricked off into thumb pots and afterwards shifted into 3-in. ones, they will be much more stocky and useful by bedding-out time than plants struck from cuttings in autumn and kept through the winter.—S. W.

Fritillaria præcox for the Conservatory.—When grown in 6-in. pots this plant is well adapted for placing in front rows on conservatory stages. Its blooms, though not very effective, are nevertheless interesting, and contrast well with the brilliant colours of other flowers with which they may be associated. They may be seen used in this way in the conservatory at the Pine-apple Nursery, where pots containing several plants are furnished with from eight to ten large drooping blossoms.—E. H.

Black Ants and Rose-buds.—The buds of our early pot Roses were nearly eaten up this season by black ants. We placed saucers of water under each plant and set them on inverted pots, which prevented further attacks. Although the ants do harm in some cases, in others they do good. During the time when our early Peaches were in bloom, myriads of them assailed the blooms, and I believe aided in setting the fruit. Next to the bee they are the most useful agents in early Peach-houses.—W. W., *Godalming*.

SOWING SEEDS.

THIS is an operation which depends wholly on when and how to sow, in what soil to sow, and what temperature to give the seeds during their germination and early growth. As to the time, a great many sow seeds too soon. Comparatively few seeds will grow in a lower temperature than 40° or 45° . Hence the risk and loss of sowing small seeds of flowers or other plants

off or checked in such a severe manner that they hardly get over their rough treatment throughout the season. A great deal of this mischievous treatment arises from sowing too early. Had the half-hardy and sub-tropical plants for the flower garden, for instance, been sown a month later, they might have been grown right on and turned into the open ground in good health and robust strength, when they would

Roses, Hyacinths, Tulips, Larkspurs, &c. After VAN HURSUM. (See p. 348).

in cold, wet soils. Better far to wait a week or a month longer for a dry, warm bed, than to sow in a cold or a wet one. If the cold earth do not always destroy seeds, it keeps them from growing, holds them fast, and weakens and injures them by delay. Even seeds sown under glass or in heat are, as a rule, sown too soon, as seedlings should have no check or arrestment of growth between the seed pot or pan and the open air. Thousands of seeds are sown early, nursed in heat or in close quarters till they become of a large size, and are then hardened

have grown away at once without remaining at a standstill for weeks or more after being planted—a not uncommon result.

Mode of Sowing.

The manner or mode of sowing is perhaps of as much importance as the time. The three great errors are—sowing too early, too deeply, and too thickly. Many seeds, especially small ones, require to be sown very shallow, or, in other words, to have little or no covering. But that is no reason why they

should be cast upon the surface and exposed to light and air; for, though there are a few seeds that will grow on the surface, fully exposed, the majority, however small, require some amount of covering. That covering should vary with the size of the seeds, and should be, at the least, as thick as the diameter of the seeds covered, and also sufficient to protect them from light and air. This is no easy matter sometimes, when some small seeds, such, for instance, as *Lobelia speciosa*, are sown in a light house or frame. The sun speedily dries the surface-covering, and unless water be applied through a very fine rose, the fresh water is apt to wash off the covering soil and expose the bare seeds to the air. A good deal of the risk would be prevented were all seeds placed in the dark until they vegetated—at least, all small seeds. Light is of no use, if not absolutely injurious, and seeds would often vegetate far sooner were they placed in darkness till they began to grow. Of course with the first signs of life they must be moved into the light, and receive waterings and other attention needed by plants. More seeds, however, are probably killed by sowing or covering too deeply than too thinly. It is no uncommon thing, especially among the inexperienced, to cover small seeds with $\frac{1}{4}$ in. or even $\frac{1}{2}$ in. of soil. Thousands so deeply covered perish. The germs either never come to life at all, or are quite unable to cope with such a huge mass or weight of covering earth. Only the larger seeds, such as those of Onions, Carrots, Turnips, &c., should be sown from $\frac{1}{4}$ in. to 1 in. in depth. Peas, Beans, and such seeds may go under ground from 2 in. to 3 in.; but smaller vegetable and flower seeds can hardly be covered too lightly, provided they are covered. Thick sowing is also to be reprobated. From the way in which valuable seeds are buddled together and thrown broadcast into heaps, one would think that they were the most worthless things in the world, and land the most costly. There cannot be a greater fault or extravagance than overcrowding seeds. It undermines the constitution of plants at starting, and it is long before they outgrow the evil effects of such treatment. Each seed should have room to grow without injuring its neighbour. Of course seeds of small plants may be sown more thickly than those of larger ones. But, relatively, they ought not really to be sown thicker. Each plant should have sufficient space to develop its cotyledons and one leaf before it is thinned or pricked out.

Temperature at which to Sow.

As to the soil in which to sow the seeds, the lighter and drier the seed-bed the better; these are the chief points, but a certain amount of heat is also necessary. Few seeds will vegetate in a lower temperature than 40° to 60° , and in a range of 20° —say from 40° to 60° —nearly all seeds will grow. Hence, after April till October, the seeds of all our hardier flowers, fruits, and vegetables, will vegetate freely in the open air; between October and April almost all seeds vegetate with more certainty and dispatch under the protection of glass. There is no better place for raising seeds than a slight hot-bed formed of a yard or so in depth of equal parts of manure and leaves; this will afford a gentle heat of from 45° to 50° or more, in which most seeds will grow freely; the surface should be covered with about 4 in. of light sandy loam, and the seeds sown should then be covered lightly, and shaded till they begin to vegetate. Similar soil is the best suited for the raising of seeds in the open air; but any ordinary garden soil in beds, borders, or kitchen garden, will do for the raising of seeds, if it be not too wet or too rich. Dry or burnt earth, ashes, charred refuse, and even sand, are useful for seed-raising, not only as affording a light, dry bed, but as providing a friable texture in the earth, which is favourable to the multiplication of young roots. Generally, as regards the proper temperature for the germination and early growth of seeds, much depends on the character of the plant, whether a native of temperate or tropical climes, and other characteristics. For instance, a Cabbage-seed will vegetate in a temperature of 40° ; a Cucumber requires 70° ; a Pea, again, will grow in any temperature a little above 32° , or the freezing point. Celery, though a native of our salt marshes and ditches, will hardly vegetate freely under a temperature of 60° or 65° . Possibly almost every seed has its best vegetating and seed-growing temperatures, could we but know them. In general terms, the majority of

hardy plants vegetate freely in a temperature ranging from 40° to 50° ; half-hardy and tender plants require from 55° to 65° or 70° . It may also be stated, as a principle, that many seeds seem to require a higher temperature to induce them to vegetate freely than is needed for the plants afterwards. The latter, however, require careful nursing, and one of the best investments in horticulture is a little extra care and skill in rearing young plants to the planting-out stage.—D. T. FISH.

HARDY FLOWERS IN LONDON GARDENS.

THE cold cutting winds which we have experienced during the past week have been unfavourable for the opening of May flowers, as well as for the endurance of those already expanded. Amongst the most effective subjects now to be found are Tulips, *Triteleias*, late *Narcissi*, and the Hyacinth-like spikes of *Scilla campanulata major*. In Mr. Parker's nursery *Fritillaria latifolia* is very showy, quantities of its large bell-shaped, dark-spotted blossoms being produced even on small plants. *F. Meleagris alba* is also just now at its best; and the white waxy-looking flowers of *Ranunculus alexandrinus* are being produced in profusion. Amongst Grape Hyacinths the best is *Muscari (Botryanthus) Szovitzianum*, the large clusters of dark blue blossoms of which are produced in great profusion where the soil is warm and well drained. *Pulmonaria azurea* is beginning to push up trusses of bright blue blossoms, which, contrasted with the double-flowered variety of *Ranunculus bulbosus* and of *Caltha palustris*, are very effective. The Cape Pondweed (*Aponogeton distachyon*) is now producing abundance of large Hawthorn-scented blossoms, and Primroses and *Polyanthuses* continue to be everywhere very attractive. *Primula cortusoides* is flowering freely in sheltered positions, as is also *P. erosa* and *P. denticulata*; *Orobanchium luteum*, too, is just beginning to throw up its yellowish clusters of Pea-shaped flowers, and Forget-me-Nots, Catchflies, and Pansies, are coming everywhere into full flower. The Common Honesty (*Lunaria biennis*) is also very showy in some of the London market gardens, and the *Doronicums* are covered with large yellow showy flowers. S.

***Mentha gibraltaria*.**—This is a desirable addition to lists of hardy plants suitable for carpet bedding. It is one of the easiest plants to propagate with which I have ever had anything to do, and it may be increased with wonderful rapidity. It is not every hardy plant that will bear rapid forcing for cuttings early in spring, but this Pennyroyal seems to revel in strong heat and moisture. It is hardly necessary to talk about taking cuttings, as its growth hugs the soil, and throws out roots at every joint; therefore all one has to do is to keep cutting off little plants and potting them, or planting them in shallow boxes, and in a very short time they in their turn will bear cutting up in like manner. The English species of Pennyroyal delights in somewhat damp and shady situations, and therefore in porous soils this will probably require to be liberally supplied with water, but now that softer quieter tints are becoming better appreciated, this plant, on account of its close, neat style of growth, will certainly be a great acquisition.—E. HOBDAV.

Common Honesty (*Lunaria biennis*) in spring.—This useful plant is not nearly so often met with as it ought to be. In shrubby borders and in half-shady situations it is very effective, and succeeds well in any light garden soil. In April and May it throws up numerous branching racemes of purplish rose-coloured blossoms, which are sweetly scented and very useful for cutting. I saw a large quantity of this plant growing in a market garden near London a short time ago, and the effect which it produced was very striking. The plants were growing between fruit trees, where they appeared to thrive remarkably well, and in autumn they yield a good supply of bright silvery pods, for the production of which they are expressly grown. These seed-vessels are extensively used at Christmas time in the manufacture of crosses, wreaths, and similar devices.—J. B.

New Hose-in-Hose Polyanthus.—I have just seen a truss of flowers of a golden yellow Hose-in-Hose Polyanthus, that promises to be an acquisition. It is a duplicate, as far as size and appearance are concerned, of Golden Gem, now so familiar to visitors at the South Kensington shows, but it greatly exceeds that kind in its deep rich orange-yellow tint. The white Hose-in-Hose is not quite so scarce as

Double Monkshood-leaved Crowfoot
(*Ranunculus aconitifolius* fl.-pl.)

Parnassia-leaved Crowfoot
(*Ranunculus parnassiaefolius*).

Caucasian Leopard's-bane
(*Doronicum caucasicum*).

Perennial Honesty (*Lunaria rediviva*).

Common Musk (*Mimulus moschatus*).

Veitch's Primrose (*Primula cortusoides amœna*).

Compact-growing Catchfly
(*Silene compacta*).

Double-flowered Asiatic Crowfoot
(*Ranunculus asiaticus* fl.-pl.).

Yellow-flowered Orobanch
(*O. luteus*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

I had imagined; for recently whilst in Hampshire I met with a large quantity of it, and was pleased to find that it makes a good spring bedding plant. In the same place I also found in quantity the Double Red Polyanthus named King Theodore, and the old-fashioned Jack-in-the-Green, both very interesting border flowers, but not to be commended as bedding plants.—A. D.

PLATE LXXII.

ROSES REYNOLDS HOLE AND FRANCOIS
MICHELON.

Drawn by H. NOEL HUMPHREYS.

THERE are incidents in life which make humility difficult:—when we succeed, after many failures, in smoking a cigar without feelings of nausea; when we first see some miserable verses or silly letters, which we have sent to the local newspaper, inserted by the kind editor to please our parents; when we bring down our first woodcock, or bring home our first brush; when we hit Ripper to square leg for five, or leave Brag on the wrong side of a nasty stile; or, when we see a magnificent Rose, exquisitely painted in THE GARDEN newspaper, or growing and glowing in the garden itself, and lo! it bears our name (not always, by the way, correctly spelt; for I have seen it written and printed "Reynold's Hole," as though Reynold were some brigand or badger; and, on one occasion, finding myself designated as "Reynard's Hole," I ventured to suggest to the writer of the tally that I was a Rose and not a Fox-glove). But who, returning, would not feel himself elated as he gazed, who would not stand in need of some restraint upon his vanity, and confess that he "required the cooper?" And he who asks the meaning of these latter words shall have it in a capital story. No long time since, in one of the midland counties, a young farmer, very much in love with himself, and never weary of assuring his companions what an admirable fellow he was, rode over to visit a neighbouring friend, to whom he enlarged for two or three hours upon his own various virtues and achievements. His host, though well known for his keen sense of humour and caustic power of satire, went through the ordeal with external assent and smile; but when the departing guest had his foot in the stirrup, he put the question, "Are you going home through the town?" (I must not give the name). "Yarse, he was going home by the town." "And did he know the cooper's shop?" "Yarse, the fellar with a lot of barrels." "Well, then," said his host, "if you'll take my advice, you'll stop at the cooper's on your way home, and ask him to put a couple of hoops round your waist, or you'll bust with self-importance."

Reynolds Hole is indeed a glorious Rose, and Mr. Noel Humphreys has most faithfully reproduced its brilliant colouring, or it would, perhaps, be more accurate to say, one of the most beautiful phases of its colouring, for it has many varying hues under differing influences of climate, bright scarlet and deep purple-crimson being the two prevailing tints. It was raised by one of the Seven Champions of Rose-growing Christendom (we shall see who the other six are when we fight the wars of the Roses in Saint James's Hall on the coming 4th of July), Mr. George Paul, of the Old Nurseries, Cheshunt, Herts, and was a scion from the Duke of Edinburgh, also one of the Cheshunt seedlings. The Rose was always remarkable for its rich and brilliant colour, and the raiser was always confident of its merits as a distinct acquisition, but the blooms first exhibited were not quite large enough to satisfy the rosarian, and the season of 1875 was adverse to its development. It seemed to many, my sorrowful self included, to be a failure, when in the summer of 1876, upon established plants, it surprised and charmed us all with its brilliant beauty, and took its place as an equal amid the grandest Roses of its class, Louis Van Houtte, Monsieur Boncenne, Pierre Notting, and Xavier Olibo.

François Michelin, his associate in the accompanying plate, par nobile fratrum, was sent to England, in the autumn of 1870, by Mons. Levet, to whom we were previously indebted for Madame Therese Levet, and Paul Neron, and who at the same time enriched us with that magnificent gift, Etienne

Levet, I question whether any raiser of Roses ever sent out two such admirable novelties together, both of them to be included, in selecting this premier twelve; indeed, they are not to be surpassed, when shown in their perfection, for symmetry and for size. I need not describe François Michelin—the reader has it before his eyes.

I cannot forego this opportunity of congratulating rosarians upon the bright, pleasant prospects before us. In the first place the National Rose Society, so happily suggested by Mr. Dombrain, and so heartily promoted by his friends, will bring us into closer union and brotherhood, and will give us the Rose Show of the year, in the Hall of St. James. Moreover, this exhibition will probably surpass any of its predecessors, because, in the second place, the Rose trees themselves are in admirable condition, the wood being thoroughly ripened, and not at all injured by frost. If we can only escape those bitter severities of May, which sometimes haunt us like nightmares, and will hardly let us sleep in our beds, as we dream of Captain Christy starved and frost bitten, like Captain Burnaby in his "Ride to Kliya," we shall have a marvellous exposition of Roses. Whoever wins Messrs. Cranston and Mayo's fifty-guinea cup, will, I fear, "require the cooper"; but be this as it may, he will, I feel sure, include in his victorious collection François Michelin and REYNOLDS HOLE.

Hardy Primulas.—I have for the first time the somewhat shy-flowering *Primula Munroi* in bloom, but, compared with some of the more robust Alpine kinds, its beauty is not great. Two of the very handsomest of the early kinds are without doubt the intermedia and nivea varieties of *viscosa*, the rich maroon-purple of the one contrasting favourably with the pure white of the other. *P. villosa*, *integrifolia*, and *minima* are shy bloomers, but are exceedingly pretty, and they are kinds which should be in every collection. The leaves of *P. minima* resemble in a marked degree those of some miniature Palm, whilst the foliage of *P. integrifolia* is long and pointed and very distinct. *P. marginata* has very pleasing foliage, and is worthy of cultivation on that account alone.—A.

Auriculas at the Crystal Palace.—The powerful hold which old-fashioned hardy flowers still have upon the public taste was well manifested at the Crystal Palace on the 24th ult., when the people flocked in thickening crowds around the tables to inspect the Auriculas, Polyanthuses, and Pansies that covered them. It is one of the charms of these and kindred hardy plants that their beauties cannot be seen at a glance; they must be looked into and admired in detail, and not in the mass, as is the case when gorgeous and variously-coloured banks of Azaleas or Pelargoniums are concerned. It was truly pleasing to listen to the quaint criticisms to which the flowers were subjected by the genuine old florists present, many of whom had come long distances to share in the enjoyment provided for them at such a gathering. To the outside public green edge, grey edge, or self, paste, body and pip, are all terms absolutely unintelligible until some patient professional cultivator or florist explains their meaning, and then the instruction is received with avidity. Not only old florists, but amateurs of the true type of horticultural patron, gathered in considerable force to see the show, and the great interest there displayed bodes well for the future, not only as regards the Auricula, but also as respects many other kindred hardy plants. To those who have wealth and leisure the cultivation of the Auricula holds out special inducements, as it is a flower that peculiarly appreciates the care and attention that those having leisure and liking for it only care to give. The remarkable success that attended upon the Rev. Mr. Horner, although resident so far north as Ripon, and somewhat restricted in his means of cultivation, clearly shows that it is not the quantity grown nor the amount of labour at disposal, but rather the constant watchfulness and tender care of the true florist that secures success. So beautiful were the Auriculas that one turned to the Polyanthuses somewhat reluctantly, as these, with a few exceptions, were but sorry examples of what constitutes quality in that popular, old-fashioned flower. With the advent of the beautiful fancy and self forms has grown up an appreciating taste for them as exhibition flowers, and although it is an undoubted mistake to put these and the gold-faced kinds into competition, yet at the Palace, as at the Aquarium last year, the latter section found their charms paled by the more abundant beauties of the fancy varieties. It is specially satisfactory, however, to find that the interest created by the Palace show is already bearing good fruit, and no doubt next year the Polyanthus will be better represented.—A. D.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 338).

Garlick.

- (1) *Bottom*. And, most dear actors, eat no Onions nor Garlick, for we are to utter sweet breath.
A Midsummer Night's Dream, act iv., sc. 2.
- (2) *Lucio*. He would mouth with a beggar, though she smelt brown bread and Garlick.
Measure for Measure, act iii., sc. 2.
- (3) *Hotspur*. I had rather live
With cheese and Garlick in a windmill.
1st Henry IV., act iii., sc. 1.
- (4) *Menenius*. You that stood so much
Upon the voice of occupation, and
The breath of Garlick eaters.
Coriolanus, act iv., sc. 6.

There is something almost mysterious in the Garlick that it should be so thoroughly acceptable, almost indispensable, to many thousands, while to others it is so horribly offensive as to be unbearable. The Garlick of Egypt was one of the delicacies that the Israelites looked back to with foud regret, and we know from Herodotus that it was the daily food of the Egyptian labourer; yet, in later times, the Mahomedan legend recorded that "when Satan stepped out from the Garden of Eden after the fall of Man, Garlick sprang up from the spot where he placed his left foot, and Onions from that which his right foot touched, on which account perhaps Mohammed habitually fainted at the sight of either." It was the common food also of the Roman labourer, but Horace could only wonder at the "dura messorum ilia" that could digest the plant "cicutis allium nocentius." It was, and is the same with its medical virtues. According to some it was possessed of every virtue, so that it had the name of Poor Man's Treacle (the word treacle not having its present meaning, but being the Anglicised form of theriacle, or heal-all), while on the other hand Gerarde affirmed "it yieldeth to the body no nourishment at all; it ingendreth naughty and sharpe bloud." If we could only divest it of its evil smell, the wild Wood Garlick would rank among the most beautiful of our British plants. Its wide leaves are very similar to those of the Lily of the Valley, and its starry flowers are of the very purest white. But it defies picking, and where it grows it generally takes full possession, so that I have known several woods—especially on the Cotswold Hills—that are to be avoided when the plant is in flower. The woods are closely carpeted with them, and every step you take brings out their fœtid odour. There are many species grown in the gardens, some of which are even very sweet-smelling (as *A. odorum* and *fragrans*); but these are the exceptions, and even these have the Garlick scent in their leaves and roots. Of the rest many are very pretty and worth growing, but they are all more or less tainted with the evil habits of the family.

Gilliflowers (see Carnations).**Gooseberries.**

Falstaff. All the other gifts appertinent to man, as the malice of this age shapes them, are not worth a Gooseberry.
2nd Henry IV., act i., sc. 2.

The Gooseberry need not detain us, except to make a passing note that the name has nothing to do with the goose. Dr. Prior has satisfactorily shown that the word is a corruption of "Crossberry."

Gorse or Goss.

Ariel. Toothed Briars, sharp Furzes, pricking Goss and Thorns.
Tempest, act iv., sc. 1.

In speaking of the Furze (which see), I said that in Shakespeare's time the Furze and Gorse were probably distinguished, though now the two names are applied to the same plant. Mr. Beisley has, I think, proved this, when he says:—"The plant here called Pricking Goss is the *Genista anglica*, Petty Whin," called Goss in and previously to the time of Shakespeare. In the 15th Henry VI. (1436), Humfrey, Duke of Gloucester, had license to enclose 200 acres of land—"pasture, wode, Hethe, Vrises, and Gorste, Bruere, et Jampnorum." Rot: Parl: IV., 498 (Shakspeare's Garden, p. 12.) This does not prove that

Gorse = *Genista anglica*, but it proves that the "Gorst" was different from the "Vrise," and it may very likely have been the Petty Wbin. "Pricking Goss," however, may be only a generic term, like Bramble and Brier, for any wild prickly plant.

Gourd.

Pistol. For Gourd and Fullam holds.
Merry Wives, act i., sc. 3.

I merely mention this to point out that "Gourd," though probably originally derived from the fruit, is not the fruit here, but is an instrument of gambling.

Grapes (see Vines).**Grass.**

- (1) *Gonzalo*. How lush and green the Grass looks.
Tempest, act ii., sc. 1.
- (2) *Iris*. Here, on the Grass-plot, in this very place
To come and sport.
Ibid., act iv., sc. 1.
- (3) *Ceres*. Why hath thy Queen
Summoned me hither to this short-grassed green?—*Ibid.*
- (4) *Lysander*. When Phœbe doth behold
Her silvery visage in the watery glass
Decking with liquid pearl the bladed Grass.
A Midsummer Night's Dream, act i., sc. 1.
- (5) *King*. Say to her, we have measured many miles
To tread a measure with her on this Grass.
Boyet. They say that they have measured many a mile
To tread a measure with you on the Grass.
Love's Labour's Lost, act v., sc. 2.
- (6) *Clown*. I am no great Nebuchadnezzar, sir, I have not much skill
in Grass.
All's Well That Ends Well, act iv., sc. 5.
- (7) *Lucio*. If thou art changed to-night, 'tis to an ass.
Dromio of Syracuse. 'Tis true; she rides me, and I long for Grass.
Comedy of Errors, act ii., sc. 2.
- (8) *Bolingbroke*. Here we march
Upon the Grassy carpet of the plain.
Richard II., act iii., sc. 3.
- (9) *King Richard*. And bedew
Her pasture's Grass with faithful English blood.
Ibid.
- (10) *Ely*. Grew like summer Grass, fastest by night,
Unseen, yet creseive in its faculty.
Henry V., act i., sc. 1.
- (11) *King Henry*. Mowing like Grass
Your fresh-fair virgins and your flowering infants.
Ibid., act iii., sc. 3.
- (12) *Grandpre*. And in their pale dull mouths the gimmal bit
Lies foul with chew'd Grass, still and motionless.
Ibid., act iv., sc. 2.
- (13) *Suffolk*. Though standing naked on a mountain top
Where biting cold would never let Grass grow.
2nd Henry VI., act iii., sc. 2.
- (14) *Cade*. All the realm shall be in common, and in Cheapside shall my
palfrey go to Grass.
Ibid., act iv., sc. 2.
- (15) *Cade*. Wherefore on a brick wall have I climbed into this garden,
to see if I can eat Grass or pick a Sallet another while, which is
not amiss to cool a man's stomach this hot weather.
Ibid., act iv., sc. 10.
- (16) *Cade*. If I do not leave you all as dead as a door-nail, I pray God
I may never eat Grass more.
Ibid.
- (17) *1st Thief*. We cannot live on Grass, on berries, water,
As beasts and birds and fishes.
Timon of Athens, act iv., sc. 3.
- (18) *Saturninus*. These tidings nip me, and I hang the head
As flowers with frost or Grass beat down with storm.
Titus Andronicus, act iv., sc. 4.
- (19) *Hamlet*. Ay, sir, but while the Grass grows—the proverb is some-
thing musty.
Hamlet, act iii., sc. 2.
- (20) *Ophelia*. He is dead and gone, lady,
He is dead and gone,
At his head a Grass-green turf,
At his heels a stone.
Ibid., act iv., sc. 5.

In the whole range of botanical studies the accurate study of the Grasses is, perhaps, the most difficult as it is the most extensive, for Grasses are said to "constitute, perhaps, a twelfth part of the described species of flowering plants, and at least nine-tenths of the number of individuals comprising the vegetation of the world" (Lindley), so that a full study of the Grasses may almost be said to be the work of a lifetime. But Shakespeare was certainly no such student of Grasses: in all these passages Grass is only mentioned in a generic manner, without any reference to any particular Grass. The passages in which hay is mentioned, I have not thought necessary to quote.

Harebell.

Arctagrus.

Thou shalt not lack
The flower that like thy face, pale Primrose, nor
The azure Harebell, like thy veins.
Cymbeline, act iv., sc. 2. (See Eglantine).

The Harebell of Shakespeare is undoubtedly the Wild Hyacinth (*Scilla nutans*), though we must bear in mind that the name is applied differently in various parts of the island; thus the Harebell of Scotch writers is the Campanula, and the Bluebell, so celebrated in Scottish song, is the wild Hyacinth or Scilla; while in England the same names are used conversely, the Campanula being the Bluebell and the Wild Hyacinth the Harebell" (Poets' Pleasance)—but this will only apply in poetry; in ordinary language, at least in the south of England, the wild Hyacinth is the Bluebell, and is the plant referred to by Shakespeare as the Harebell. It is one of the chief ornaments of our woods, growing in profusion wherever it establishes itself, and being found of various colours—pink, white, and blue. As a garden flower it may well be introduced into shrubberies, but as a border plant it cannot compete with its rival relation, the Hyacinthus orientalis, which is the parent of all the fine double and many-coloured Hyacinths in which the florists have delighted for the last two centuries.

Harlocks.

Cornelio.

Crowned with rank Fumiter and farrow weeds,
With Harlocks, Hemlock, Nettles, Cuckoo-flowers.
King Lear, act iv., sc. 4. (See Cuckoo-flowers).

I cannot do better than follow Dr. Prior on this word:—"Harlock, as usually printed in *King Lear* and in Drayton, ecl. 4—

The Honeysuckle, the Harlocke,
The Lily and the Lady-smocke,

is a word that does not occur in the Herbals, and which the commentators have supposed to be a misprint for Charlock. There can be little doubt that Harlock is the correct reading, and that the plant meant is the one now called Burdock."

Hawthorns.

(1) *Rosalind.* There's a man hangs odes upon Hawthorns and elegies on Brambles.

As You Like It, act iii., sc. 2.

(2) *Quince.* This green plot shall be our stage, this Hawthorn brake our tiring house.

Midsommer Night's Dream, act iii., sc. 1.

(3) *Helena.* Your tongue's sweet air,
More tunable than lark to shepherd's ear,
When Wheat is green, when Hawthorn-buds appear.

Ibid., act i., sc. 1.

(4) *Falstaff.* I cannot cog and say thou art this and that, like a many of these hisping Hawthorn-buds.

Merry Wives, act iii., sc. 3.

(5) *K. Henry.* Gives not the Hawthorn bush a sweeter shade
To shepherds, looking on their silly sheep,
Than doth a rich embroidered canopy
To kings that fear their subjects' treachery?
O yes, it doth, a thousandfold it doth.

3rd Henry VI., act ii., sc. 5.

(6) *Edgar.* Through the sharp Hawthorn blows the cold wind (*bis*).

King Lear, act iii., sc. 4.

Under its many names of Albespine, Whitethorn, Haythorn or Hawthorn, May, and Quickset, this tree has ever been a favourite with all lovers of the country.

Amongst the many buds proclaiming May,
Decking the fields in holiday array,
Striving who shall surpass in braverie,
Marke the faire blooming of the Hawthorn tree,
Who, finely clothed in a robe of white,
Fills full the wanton eye with May's delight.

Such is Chaucer's advice. He clearly loved the tree for its beauty, and in picturesque beauty the Hawthorn yields to none, when it can be seen in some sheltered valley growing with others of its kind, and allowed to grow unpruned, for then in the early summer it is literally a sheet of white, yet beautifully relieved by the tender green of the young leaves, and by the bright crimson of the anthers, and loaded with a scent that is most delicate and refreshing. But not only for its beauty is the Hawthorn a favourite tree, but also for its many pleasant associations—it is essentially the May tree, the tree that tells that winter is really past, and that summer has fairly begun. Hear Spenser—

Thilke same season, when all is yelade
With pleasaunce; the ground with Grasse, the woods
With greene leaves, the bushes with blooming buds,
Youngthe's folke now flocken in everywhere
To gather May-baskets and smelling Breere;
And home they hasten the postes to dight
And all the kirk-pillours eare day-light
With Hawthorne-buds, and sweet Eglantine,
And girondes of Roses, and Soppes-in-wine.

Shepherd's Calendar—May.

Yet in spite of its pretty name, and in spite of the poets, the Hawthorn now seldom flowers in May, and I should suppose it is never in flower on May Day, except perhaps in Devonshire and Cornwall; and it is very doubtful if it ever were so found, though some fancy that the times of flowering of several of our flowers are changed, and in some instances largely changed. But "it was an old custom in Suffolk in most of the farm-houses that any servant who could bring in a branch of Hawthorn in full blossom on the 1st of May was entitled to a dish of cream for breakfast. This custom is now disused, not so much from the reluctance of the masters to give the reward, as from the inability of the servants to find the Whitethorn in flower" (Brand's "Antiquities.") Even those who might not see the beauty of an old Thorn tree, have found its uses as one of the very few trees that will grow thick in the most exposed places, and so give pleasant shade and shelter in places where otherwise but little shade and shelter could be found.

Every shepherd tells his tale
Under the Hawthorn in the dale.—*Milton.*

And "at Heskett, in Cumberland, yearly on S. Barnabas' Day, by the highway side under a Thorn tree is kept the court for the whole forest of Englewood."—"History of Westmoreland.")

The Thorn may well be admitted as a garden shrub either in its ordinary state, or in its beautiful double white, red, and pink varieties, and those who like to grow curious trees should not omit the Glastonbury Thorn, which flowers at the ordinary time, and bears fruit, but also buds and flowers again in winter, showing at the same time the new flowers and the older fruit.

Nor must we omit to mention that the Whitethorn is one of the trees that claims to have been used for the sacred Crown of Thorns. It is most improbable that it was so, in fact, almost certain that it was not; but it was a mediæval belief, as Sir John Mandeville witnesses:—"Then was our Lord yled into a gardyn, and there the Jewes scorned hym, and maden hym a crowne of the branches of the Albespyne, that is Whitethorn, that grew in the same gardyn, and setten yt upon hys heved. And therefore hath the Whitethorn many virtues. For he that beareth a branch on hym thereof, no thundre, ne no maner of tempest may dere hym, ne in the howse that it is ynne may non evil ghost enter."

And we may finish the Hawthorn with a short account of its name, which is interesting:—"Haw," or "hay," is the same word as "hedge" (sepes, id est, *haies*—John de Garlande), and so shows the great antiquity of this plant as used for English hedges. In the north, "haws" are still called "haigs;" but whether Hawthorn was first applied to the fruit or the hedge, whether the hedge was so called because it was made of the Thorn tree that bears the haws, or whether the fruit was so

named because it was borne on the hedge tree, is a point on which etymologists differ.

Hazel.

- 1 *Mercurio*. Her [Queen Mab's] chariot is an empty Hazel nut,
Made by the joiner squirrel or old grub,
Time out of mind the fairies' coachmakers.
Romeo and Juliet, act i., sc. 4.
- (2) *Petruchio*. Kate, like the Hazel twig,
So straight and slender, and as brown in hue
As Hazel-nuts and sweeter than the kernels.
Taming of Shrew, act ii., se. 1.
- (3) *Caliban*. I'll bring thee to clustering Fillberds.
Tempest, act ii., se. 2.
- (4) *Touchstone*. Sweetest Nut hath sourest rind,
Such a Nut is Rosalind.
As You Like It, act iii., se. 2.
- (5) *Celia*. For his verity in love I do think him as concave as a covered
goblet or a worm-eaten Nut.
Ibid., act iii., se. 4.
- (6) *Lafeu*. Believe me, my lord, there can be no kernel in this light Nut.
All's Well That Ends Well, act ii., se. 5.
- (7) *Mercurio*. Thou wilt quarrel with a man for cracking Nuts, having
no other reason but because thou hast Hazel eyes.
Romeo and Juliet, act iii., se. 1.
- (8) *Thersites*. Hector shall have a great catch if he knock out either of
your brains, 'a' were as good crack a fusty Nut with no kernel.
Troilus and Cressida, act ii., se. 1.
- (9) *Gonzalo*. I'll warrant him from drowning, though the ship were no
stronger than a Nut-shell.
Tempest, act i., se. 1.
- (10) *Titania*. I have a venturous fairy that shall
Seek the squirrel's hoard and fetch thee new Nuts.
Midsummer Night's Dream, act iv., se. 1.
- (11) *Hamlet*. O God! I could be bounded in a Nut-shell and count myself
self a king of infinite space, were it not that I have had dreams.
Hamlet, act ii., se. 2.

Dr. Prior has decided that "'Filbert' is a barbarous compound of *phylon* or *feuille*, a leaf, and *beard*, to denote its distinguishing peculiarity, the leafy involucre projecting beyond the nut." But in the times before Shakespeare the name was more poetically said to be derived from the nymph Phyllis. Nux Phyllidos is its name in the old vocabularies, and Gower (*Confessio amantis*) tells us why:—

Phyllis in the same throwe
Was shape into a Nutte-tree,
That alle men it might see;
And after Phyllis philliberde,
This tre was cleped in the yerde—(Quoted by Wright).

The Nut, the Filbert, and the Cobnut are all botanically the same, and the two last were cultivated in England long before Shakespeare's time.

There is a peculiarity in the growth of the Nut that is worth the notice of the botanical student. The male blossoms, or catkins (also anciently called "agglottes or blowinges") are mostly produced at the ends of the year's shoots, while the pretty little crimson female blossoms are produced close to the branch; they are completely sessile or unstalked. Now in most fruit trees, when a flower is fertilized, the fruit is produced exactly in the same place, with respect to the main tree, that the flower occupied; a Peach or Apricot, for instance, rests upon the branch which bore the flower. But in the Nut a different arrangement prevails. As soon as the flower is fertilized, it starts away from the parent branch; a fresh branch is produced bearing leaves and the Nut or Nuts at the end, so that the Nut is produced several inches away from the spot on which the flower originally was. I know of no other tree that produces its fruit in this way, nor do I know what special benefit to the plant arises from this arrangement.

Much folk-lore has gathered round the Hazel tree and the Nuts. The cracking of Nuts, with much fortune-telling connected therewith, was the favourite amusement on All-Hallows Eve (Oct. 31), so that the Eve was called Nutcrack Night. I believe the custom still exists; it certainly has not been very long abolished, for the Vicar of Wakefield and his neighbours "religiously cracked Nuts on All-Hallows Eve." And in many places "an ancient custom prevailed of going a Nutting

on Holy Rood Day (Sept. 14), which it was esteemed quite unlucky to omit" (Forster).

A greater mystery connected with the Hazel is the divining rod, for the discovery of water and metals. This has always by preference been a forked Hazel-rod, though sometimes other rods are substituted. The belief in its powers dates from a very early period, and is by no means extinct. I believe the divining-rod is still used in Cornwall, and firmly believed in; nor has this belief been confined to the undeducated. Even Linnæus confessed himself to be half a convert to it, and learned treatises have been written, accepting the facts, and accounting for them by electricity or some other subtle natural agency. Most of us, however, will rather agree with Evelyn's cautious verdict, that the virtues attributed to the forked-stick "made out so solemnly by the attestation of magistrates, and divers other learned and credible persons, who have critically examined matters of fact, is certainly next to a miracle, and requires a strong faith." H. N. ELLACOMBE.

(To be continued).

THE KITCHEN GARDEN.

TURNIP CULTURE.

TURNIPS may be had in good condition nearly ten months in the year by sowing a little seed at various times from the first week in March to the last day in July. A light gravelly soil, well broken up, is that which is most favourable to the production of good Turnips, but they will succeed in all sorts of soils if properly prepared. Gardens that are situated somewhat low and moist, with a moderately rich, well-cultivated soil, will produce early Turnips of the best quality, though such gardens are unsuitable for the generality of spring crops. The first crop should be sown about the last week in March, in an open situation, where the ground is light. When sown two or three weeks after midsummer, and the plant becomes established, there is no difficulty in securing a crop on tolerably well-managed land. Others to succeed those sown the previous month should be put in about the end of April. This crop will be ready for use by the end of June; those sown at the end of March, if they escape the flea, will be ready for use by the first week in June. Another sowing should be made early in June, and a sowing for the main crop about the first week in July. In all cases locality must decide the time to sow the last crop. As a rule, large Turnips are not required; therefore they should be sown just soon enough to insure roots about the size of one's fist. It is a good plan to make two sowings at an interval of a fortnight from each other. Turnips are in all cases best in drills about 1 in. deep and 14 in. apart. Late crops should be sown rather wider apart than earlier ones, in order that light and air may circulate freely among the foliage and about the roots, otherwise the leaves get watery and incapable of resisting severe weather. As soon as the plants have made leaves 1 in. in width, the hoe must be at work amongst them, cutting up weeds and stirring up the ground. They should be thinned to about 12 in. from each other in the rows. In dry weather give them a good soaking or two of water, and hoe between the rows at least once a week. I ought to have stated that it is not essential that the ground should be prepared just previous to sowing the seed, it being an advantage to have it prepared some time beforehand, when it is not required for other purposes. In all gardens of limited dimensions every inch of ground is an object, and the moment one crop is gathered the ground should be turned up and planted with another. Manure freely and dig deeply, and the soil will be capable of bringing to perfection two, three, or even four crops in one season. For early sowings of Turnips, the best are Early American Stone Strapleaf, which is very early and good; Early White Dutch, a sort that becomes quickly fit for use; Early White Stone; and Early Snowball. For the main crop there is nothing better than Red Globe; it is an excellent variety, and it has the good property of remaining a long time fit for use. For late winter use Orange Jelly and Chirk Castle are fine hardy sorts; the flesh of the latter is beautifully white, though the outside is nearly black, and the flavour is good; but the flesh of the former is yellow, and,

therefore, to some objectionable. The greatest enemy to the Turnip crop is the fly, which is most to be feared in fine, sunny seasons; heavy rains and cold springs destroy them. One remedy is to dust the ground all over with quick-lime as soon as the plants appear above the surface; this, in most cases, is effectual. Some apply gas-lime three or four days after sowing the seed; sifted wood-ashes, put on as soon as the plants show their seed-leaves, have also proved an effectual remedy.

R.

POTATO PLANTING.

A NUMBER of years ago, a German cultivator caused some sensation by stating that the productive power of the Potato could be marvellously increased by a system of culture which he had discovered. His plan, if we remember rightly, was to plant whole sets of the largest size, and those with the greatest number of eyes, and he planted them some 6 in. or 8 in. deep, with the eyes downwards, as far as practicable, and allowed each plant 12 square ft. or 16 square ft. of space to itself; or, in other words, he placed the sets some 4 ft. asunder each way. Placing the eyes downwards caused the shoots to make a détour, as it were, and to spread out on the surface of the ground; advantage was taken of this to make the shoots extend as much as possible on all sides, mounding up being accomplished by placing a hillock or earth in the centre of the plant and over the base of each stem for some considerable distance, pressing them all downwards and outwards at the same time, so as to admit light and air, and get as great a breadth of haulm as possible. We forget now what was the weight of the produce of each root; but the crop was said to be enormous, and we can quite believe it. Such a practice is not to be recommended in general culture; but it is very suggestive nevertheless, and shows the advantage and necessity of giving the tops of the Potato plant room, and, in a negative sense, the evils of thick planting. One good, stout stem is worth half-a-dozen small weedy ones, for the first will produce an abundance of large, sound tubers, and the second only small ones—frequently so small as to be unfit for use. Many plant much too thickly, thus encroaching upon their store for present use and injuring the future crop. We have frequently seen cottagers planting such kinds as Paterson's Victoria and Regents in rows 18 in. or less apart, and the sets about 6 in., which is allowing such strong-growing varieties just half the room which they require; but it is exceedingly difficult to get owners of allotments to believe this without actual experiment. Naturally anxious to make the most of their small piece of ground, they have no faith in the economy of wide planting. A few years ago when the disease was so bad, several cottagers' crops were in many cases a mass of rotteness, and far worse than the field crops, a circumstance which could only be attributed to thick planting, for during the wet and sultry weather the tops of all kinds grew unusually tall and thick, and covered the ground so densely that the soil never had the least chance of becoming dry or receiving a ray of sunshine; the haulm acted like a thick mulching, which invariably aggravates the disease. Like the Pea, the Potato should have room in proportion to its growth. The dwarf Kidneys and others which produce tops 12 in. or 18 in. high, should be allowed from 2 ft. to 2½ ft. between the rows, and from 9 in. to 12 in. between the sets, if whole sets be used and none of the eyes be picked out; but if only one shoot be left to a set, they may be planted a little closer. Tall sorts, like the Regents, Paterson's Victoria, and Red-skinned Flourball, require 3 ft. or 3½ ft. between the rows, and 18 in. between the sets. This is the space we give them, and they always cover the ground completely, and overlap each other considerably. Under high culture and in good soil, 6 ft. between the rows would not be too much for some strong-growing kinds; though whether it would be profitable to afford the tops as much space as they would actually occupy when they spread out over the ground, we shall not venture to say. Of one thing, however, there can be no doubt, and that is, that in wet seasons, when disease is apt to occur, it is better if the sun's rays can strike the ground between the rows. As regards the time to plant, a good deal depends upon circumstances, and there is some difference of opinion on the subject. Thus the late Mr. Andrew Knight, who is frequently quoted as an authority on the subject, says, if planting can be done by the end of February, so much the better; but, at all events, it should be finished by the 1st of March. Where Mr. Knight carried out his experiments in Potato culture, this might be true; but such early planting is not advisable in many parts of England and Scotland. In the south, and in warm, light soils, February is not too early, provided the ground is in a workable condition when the crop is put in; but in the northern and in many parts of the midland counties early main crops are not planted till April, and the late crop is often not

got in before the middle of May; and late planting is found to be the best practice. On one or two occasions we put in part of our main crop in February and March, and the remainder in April, towards the end of the month; and the later-planted crop was found to be so much superior, that we have always adhered to the practice since. We were strangers to the locality at the time, and believed in early planting; but the old farmers of the neighbourhood predicted that we should alter our practice, and they were right: the worst crop of Potatoes we ever had was planted in February. Some people are nervous if they cannot get their crops into the ground at a stated time; but it is far better to wait a fortnight, or even a month, than to attempt planting when the ground is wet and unworkable. Under such circumstances, little or no time is lost if the seed tubers be spread out thinly in a loft or in a shed where they can sprout; and if they be carefully planted, so as not to rot the sprouts off, the tops are soon above the ground, and progress rapidly. The old practice of spreading the manure in the row and planting the sets upon it is still commonly practised. In planting field crops, hardly any other plan can be conveniently adopted; but in garden culture, if the manure be given at planting time, it should be dug into the ground in the usual way, and the Potatoes set at the same time, as if no manure were there.

FIELD.

A GARDEN HORROR.

THIS is what one of our correspondents saw some time ago in the mirror globe in the new Canon Hill Park at Birmingham. Previous to that he was not without some consciousness

of an ornamental exterior; he therefore naturally protests against the employment of such barbarisms in gardens. We have before now said as much as we could against the adoption of the dreadful mirror globe of the French gardens; we however only referred to their distant effect, bad enough in the landscape to keep them out of tea-gardens of the meanest type. Canon Hill Park is well laid out, and does not require any aids of this kind.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Snow's Winter White Broccoli.—Few vegetables in January or February are so acceptable as this Broccoli when it can be obtained true to name. A little seed sown now in a good, rich bed of soil, pricking the plants out when large enough, and transplanting them to their final quarters early in June in good, firm land, will, if all go well, give a supply of snow-white heads at a time when good vegetables are scarce.—C.

Pinching Tomato Plants.—When planted in very rich soil, Tomatoes often produce much wood and little fruit. The best crop of Tomatoes I ever saw was furnished by main stems as free from side growth as a walking stick. All growths, except the leaves and flowers attached to the principal stem, had been pinched off as they appeared.—J. M.

Osborn's Forcing and Wilmot's Forcing French Beans.—I have given both of these Beans (said to be excellent forcers) a fair trial this spring; they were sown on the same day and grown on ever since in the same house; the first dish was gathered from Osborn's last week, while Wilmot's is scarcely in flower yet, and will be about three weeks later in fruiting. The pods on Osborn's are not very long, but they are produced in great numbers, and the plants are dwarf and compact in habit of growth. On the other hand, Wilmot's is inclined to run into long straggling stems, and altogether I consider it much inferior to Osborn's for culture under glass.—A NORTHERN GARDENER.

THE FRUIT GARDEN.

SOME FINE CROSSED ESPALIERS.

WE have recently noticed very fine examples of crossed espaliers in France, which may perhaps be worth illustrating. As will be seen in this case supports are dispensed with, except that of the trees themselves and a long stake or string of wire along the top as shown in the cut. The trees are plauted pretty close, and the branches so crossed that they support each other and the fruit steadily. As will be seen there are only three stages of branches on each tree, except at the end of the line where they are required to complete it. It will be observed that having obtained the three tiers of branches, the central stem is retained as a support for the intercrossing branches. It requires eight years to form a series of fine espaliers like these in the Government School at Saulsaie. The shoots at the top are to encourage the sap to flow

fit for the purpose. A ridge of light soil, 3 in. deep, should be laid along between the rows; over this the offsets should be laid, and the runners beyond pinched off. Place a stone a few ounces in weight behind the young plant to keep it in its place, and when it pushes, pinch again. In this way a young plant is much sooner formed than by waiting till the first offsets have formed several leaves, by which time others have formed beyond them, thus robbing the earliest of their vigour. After layering they should be watered frequently, if the weather be dry, and in three or four weeks the plants will be rooted and ready for potting. A few days before potting, however, the plants should be severed from the parent crown, which may cause them to flag a little, but they will soon recover. The best soil for the Strawberry is a light fibry loam; but if the loam be heavy, it must be reduced to the proper texture by the admixture of rotten leaf-mould and sand, and in any case a quantity of Standen's Manure, at the rate of half a teaspoonful to a 6-in. pot, should be mixed with the compost. For weaker kinds, like the Black Prince, $4\frac{1}{2}$ -in. or 5-in.

Crossed Espaliers at Saulsaie.

freely through each branch, and also to prevent very strong growth on the said branches. The form was adopted to meet the inconveniences of a very windy and exposed situation. Having seen the trees, we can vouch for their perfection of form and fertility.

STRAWBERRY FORCING.

As regards preparing the plants for forcing, it is necessary in the first place to propagate such sorts only as are found to ripen early out-of-doors, and to bear freely and constantly. This has been my guide for many years, and I have never been disappointed. All varieties do not bear alike in different localities; but a little inquiry will soon elicit the necessary information, and this is the course which I should recommend intending cultivators to pursue. It may, however, be mentioned that the Black Prince variety and Vicomtesse Héricart de Thury have hitherto proved to be free bearers and good forcers in almost all parts of the country. Runners of the earliest outdoor plants should be layered as soon as they are

pots will be large enough, and 6-in. should not be exceeded for the strongest. Nothing whatever is gained by using large pots, and both time and space are lost by them. The pots should be safely drained with from $\frac{3}{4}$ in. to 1 in. of clean crocks, not more, and in potting the soil should be made pretty firm under plants, and pressed moderately firm round their roots, leaving about half an inch for watering; it is assumed, of course, that the plants are lifted from the bed with good balls of earth, and carefully handled in potting. After they are potted the plants should be placed on ashes on a level and sheltered piece of ground, and in a warm and light situation, and at first set as closely together as the pots will stand. Then they should be well watered, and from this time till they cease growing, about the end of September, water must be supplied liberally, and weak liquid manure frequently. The secret of Strawberry forcing depends upon the culture of the plants the summer previous. An early start and liberal treatment afterwards give fine and ample foliage and strong crowns; and these once secured, if a good crop be not the result, then in nineteen cases out of twenty, the failure is owing to mismanagement. By October the plants will have ceased grow-

ing actively, and at that season water should not be given indiscriminately, but only when the plants are dry, and always in the morning—at least when frosts are expected; it is not advisable to water a plant when it is likely to be frozen. Before November the plants should be stored in dry, cool pits or houses; failing these, they may be stacked in ridges, laying the pots on their sides with the crowns outwards, and covering each row with ashes as the work proceeds. From the store pits they may be introduced into heat as wanted, in fifties or hundreds, as the case may be. It is always best to put in plenty of plants, as the fruit can easily be retarded for nearly a month after it is set if needful; and if not, frequent dishes of fruit are always acceptable. In forcing, temperature is the most important matter. A high day temperature is not injurious, if the thermometer be allowed to drop to or below 40° at night up till the setting period; but after that, if time be an object, they will stand a temperature of 90° on fine sunny days, with free ventilation; but it is always advisable to drop low at night, consistently with an early rise in the morning. In fine days the plants may be syringed once a day overhead, but not oftener, and at all times they must be well watered at the roots; but saucers to hold water should not be used. When the fruit is ripe or nearly so, it is improved in flavour by removing the plants to an airy house, where the temperature is not lower than 50°, for it requires heat, together with light and air, to give the berries a good flavour.

CHEF.

Covering Early Vinery Borders.—Does Mr. Baines realise the force of his advice on this subject (see p. 311)? I am able to inform him that a Vine border covered early in the autumn with a layer of non-conducting materials “sufficient to ward off rains and frost” merely, and not to ferment—as he recommends for outside borders of early Vineries—will decline in temperature to 50° before Christmas, 9 in. or 12 in. below the surface, and lower in severe weather. Consequently, Vines started in November or December will have their roots in a temperature of 45° or 50°, when they are supposed to be ripening their fruit, and enjoying a temperature (inside) of from 70° to 85°. If this be the treatment Mr. Baines recommends for Vines, it is very different from what he recommends for plants in his calendarial and other writings, and I should be glad to know why he makes a distinction. The temperature of an outside Vine border is about 55° or 60° “early in the autumn,” under ordinary circumstances, but a layer of non-conducting materials cannot sustain it at that figure for any length of time, for, unless the material is thick enough to ferment, the soil still continues to part with its heat, only slower. I cannot be accused, I think, of advocating high temperatures, but I do think the temperature of the border should bear some reasonable proportion to the temperature of the Vinery at all stages. I have known good Grape growers, such as those to whom Mr. Baines refers, who professed to use “non-conducting materials” only for their borders, and not hot livings, but a thermometer inserted in their coverings of leaves revealed a different state of things, and showed that the materials were not only “non-conducting” but actually “fermenting,” and thus, really, they were practising one system and advocating another.—J. SIMPSON, *Wortley*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Liquid Manure for Vines.—We are often recommended not to give manure water to Vines until the fruit is swelling. I always apply it freely from the time when the young shoots are 1 in. or 2 in. long until the fruit is colouring, and I find it do far more good in strengthening the shoots and produce before the bunches are in flower than at any subsequent period.—A NORTHERN GARDENER.

Grape Mildew.—A French authority, M. Chatot, recommends common salt as an antidote for Mildew on Vines. By sprinkling a handful of salt around the base of each Vine, the effect, he says, was marvellous; and Vines hitherto covered with this fungus, grew luxuriantly, and had an abundance of Grapes entirely free from Oidium.

Peaches and Nectarines for Succession.—When I came here I found no Peaches fit for gathering on the 7th of July; the Peaches consisted of Royal George and the Nectarines of the Elruge, and when they did ripen I had twice or thrice as many fruits as I wanted. I therefore at once determined to take up each end tree and plant Early Rivers and Early Beatrice Peaches; the latter I shall gather in ten days, and the former shortly afterwards—thus with one house I shall furnish a good supply of fruit shortly afterwards—thus with one house I shall obtain, and still have an apple later in the season as before.—R. GILBERT, *Burghley*.

Vine Borders.—In Mr. Baines's article on this subject (p. 311, line 16) for “outside” read “within.”

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Cinerarias and Primulas.—A little more Cineraria seed should now be sown to succeed the earliest batch; also Primula seed to furnish plants in bloom for the winter. Amateurs who have not had much experience in raising Primulas from seed, frequently find a difficulty with them, as the seeds are very tender and must only be very slightly covered. A good method is, after filling the seed-pans with finely-sifted soil, consisting of three-fourths loam and one of leaf-mould mixed with a little sand, and making the surface firm, to sow the seeds evenly, not using any covering of soil, but laying over the top a little chopped Sphagnum; a sheet of glass placed on the top will keep the soil sufficiently moist to cause the seed to vegetate. As soon as growth has commenced the Sphagnum must be removed, otherwise the young plants will become drawn; gradually expose them to the light.

Perennials and Biennials should now be sown; if deferred to a later period, the plants rarely get strong enough to furnish a vigorous bloom. The hardiest examples of Wallflowers, Sweet Williams, Campanulas, Dianthus, Aquilegias, Delphiniums, Foxgloves, Hollyhocks, Mimulus, Pentstemons, and Biennial Stocks may be sown in the open ground—the rest in pans placed in a cold frame. The advantage of getting them sown in good time is that it permits of their being transplanted into nursery-beds sufficiently early in the summer to attain a size and strength that will enable them to stand through the winter, and to make a good display the following season.

Vines, Peaches, and Apricots.—Attend to the stopping and training of Vines as required in the different stages of their growth; this should never be deferred for a day after the proper time, as from their naturally rapid growth their energies become so far wasted if neglected in this respect. Peaches under glass should be continually examined, removing all superabundant shoots and thinning the fruit by degrees; use the syringe freely every afternoon to keep down red spider, as if this insect make its appearance early, it is troublesome to deal with when it has obtained a firm footing. As soon as the blooming of Peaches on open walls is over, they should be closely watched for green fly; the slightest curl on the leaves is an indication of its presence. Where Lettices are grown at the foot of such walls, a few of the mature insects generally secure a lodgment on them through the winter, and from them the first brood usually are communicated to the Peaches. Immediately they are discovered on the trees, syringe the affected parts with Tobacco or Quassia-water, or soap-suds in sufficient quantity and carefully applied will destroy them. As it takes no more than a fortnight from the time the eggs are laid to the full development of the insect, it will easily be understood that any delay in searching for them early in the season should be avoided. Look over Apricots for the small green caterpillar that gets on them, and which rolls itself up in the leaves, squeezing those that are so affected between the finger and thumb; timely attention here again will save the trees from much injury.

Strawberries.—There is nothing so good as Strawberries to grow on ground that has been long cropped with ordinary culinary vegetables, as they enable the land to recover from the effects of a too long succession of roots, which have abstracted the essential plant-food-supplying elements from the soil. Strawberries, also, where well managed, are, by the nature of their growth, likely to prevent the development of weeds, as ground that has been occupied by Strawberries for some years, when properly attended to, is usually free from weeds of an annual description. The present time (previous to putting on the mulching) is the best for destroying weeds; the ground, when dry on the surface, should be carefully gone over with the hoe, so as to cut off all that are annual, and that have come up from seed; any Grass that happens to be amongst them should be hand-picked and removed. After being thus treated the mulching should be put on; this should consist of the material as it comes from the stables, litter and manure together, which is much better in every way than the clean straw which is frequently laid amongst Strawberries a short time before the fruit begins to ripen, as from the nature of the stable refuse, it lies closer to the ground, has a better appearance, and equally effects the object in keeping the fruit clear from splashings with heavy rains at the time of ripening, while its manurial elements annually applied enrich the soil sufficiently for the support of the plants to keep them in a bearing condition so long as it is advisable to retain them on the same ground; and by putting on this littery manure thus early it gets washed completely clean by the rains, so that it is not in the least offensive at the time the fruit is fit to gather: as much should be laid on as will cover the ground effectually. When first put down it ought to be about 3 in. in thickness (or even a little more will do no harm

on land that is liable to get overdry through the summer), as the greater the quantity applied, the better will it effect the objects of keeping the fruit clean, of stopping the moisture from being lost to the soil by evaporation, of keeping the ground moist so as to enable the fruit to swell to a handsome size, and of effectually preventing the growth of weeds that otherwise would again spring up through the summer.

Celery.—More Celery should now be pricked out in beds of prepared soil; give plenty of water to that pricked out some weeks ago. This vegetable is almost an aquatic, and on no account should it ever be allowed to get dry at the root, for such a condition not only stunts the growth, but if the variety happen to be such as is disposed to run prematurely to seed, a deficiency of water in the early growth is calculated to aggravate the evil.

Beans.—Sow Dwarf and Runner Beans. It is now about a fortnight later than the usual season for putting in these, but except in the most favoured localities as to soil and climate, it will be quite early enough, as the weather and the state of the land up to the present time have been prejudicial to the favourable growth of such plants. Both Dwarf and Runner Beans are amongst the tenderest vegetables that are grown, and, during their first stages, are very impatient of the slightest frost, and even when the temperature does not quite fall below freezing point, they make little or no progress. The seed also requires the ground to be in a drier and warmer condition when put in than any other vegetable, consequently the driest part of the garden must be selected for them. Sow the Dwarf varieties 2 ft. apart and from 6 in. to 9 in. asunder in the rows—the latter distance will not be too much where the ground is rich; there is nothing gained by crowding Dwarf Beans too close together, as the length of time the plants are able to keep on bearing is thereby shortened. Runner Beans ought to be grown 9 in. to 12 in. apart in the rows, and where tall sticks are obtainable, from 5 ft. to 6 ft. between the rows. If they be grown without sticks (in which way they will succeed well by pinching out the points of the shoots when they have attained a height of 2 ft. to induce them to branch out) 3 ft. between the rows will be quite enough.

Cauliflowers, Brussels Sprouts, and Broccoli.—When spring-sown Cauliflowers and Brussels Sprouts have got about 3 in. high, they should be thinned out in the seed-beds so as to leave them 6 in. apart, or if transplanted into a nursery bed at the above size, it will be still better for the plants. The beds to receive them should consist of light, open soil, tolerably rich, and about 6 in. in depth, on a hard surface of ashes; so managed, they will attain size and vigour by the time they are required to be finally planted out, and can be moved to where they are to be grown even in dry weather, as they will be found with a far greater body of roots than when allowed to remain in the seed-bed until the time of planting. The final planting can also in this way be longer deferred, thereby giving additional time for the clearing of the ground they are to occupy, which, especially in small gardens, is an advantage worth considering. Another sowing of summer Cauliflower, as well as some more Veitch's Autumn Broccoli to succeed the first sowing, should be made; also more Broccoli to come in through the winter and spring. All seeds of this description should have a good open situation away from trees and walls, under the influence of which these vegetables are often sown, the effect being that the plants always become drawn and weakly. When the ground is dry on the surface, any that has been cropped for some time should be hoed over as soon as there is an appearance of weeds; by thus disturbing them directly they vegetate, much less labour is involved in their destruction than if they be permitted to attain a considerable size. Use the implement freely, so as to stir the ground 2 in. or 3 in. deep, leaving the top as loose and open as possible, which will assist the growth of the crops.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

May 7.—Potting scarlet, pink, and white Pelargoniums. Shifting seedling Petunias into 6-in. pots. Shaking out and repotting Bovardias, and afterwards placing them in a gentle bottom-heat. Sowing Centaureas, Coreopsis, Jacobæas, and Celosias; also Marjoram and Basil, and two more rows of Scarlet Runners. Planting four rows of Celery and Lettuces on the ridges. Pricking off Basil and a frame of Celery. Staking Tree Carnations and placing them in the open air in a sunny situation. Putting in cuttings of scarlet Pelar-

goniums and *Panicum variegatum*. Watering Radish, Mustard and Cress, and other seed-beds. Getting Garibaldi Strawberries that have been forced out-of-doors to harden them off previous to planting. Hoing among all growing crops.

May 8.—Potting double-flowered Wallflowers, scented-leaved Pelargoniums, and *Deutzia gracilis*; also Ridge Cucumbers. Repotting *Cypripedium niveum* and concolor in grit, sand, and peat. Sowing pots of Mignonette and beds of Chervil. Planting Vegetable Marrows and pricking off a frame of Stocks. Dibbling in Beet seed where plants have failed to come up regularly. Putting Balsams in intermediate pits. Thinning Turnips. Stopping the shoots of Broad Beans as fast as they come into flower. Staking Collinsias and other annuals intended to flower in pots. Earthing-up spring-planted Cabbages and Cauliflowers. Hoing among Rose trees, Raspberries, Carrots, Parsnips, and Peas. Sticking Peas as they require it. Washing Camellias and syringing Peaches and Nectarines with soft soap and Tobacco-water to kill apaches.

May 9.—Sowing *Rhodanthe Manglesi* and another crop of Spinach. Pricking out East Lothian Stocks in frames, and Lettuce plants in beds out-of-doors. Putting in Coleus and *Scutellaria* cuttings. Tying Carnations and staking Delphiniums. Placing Camellias at one end of greenhouse and putting shade over them. Earthing-up Broad Beans; also French Beans in pots. Putting all spare hand-lights over French Beans in border. Filling up blanks and watering Cauliflower plantation; also watering Turnips and mulching Strawberry beds with short straw to keep the fruit clean.

May 10.—Potting Capsicums, Tomatoes, and Cucumbers; also Globe Amaranths and Petunias. Putting *Lælia alba* in large pan, and hanging *Dendrobium crystallinum* in East India-house. Sowing another crop of Turnips, Lettuces, and French Beans. Staking Heliotrope and Mignonette in pots. Tying down Peach shoots so as to expose the fruit to the sun. Thinning Grapes and stopping late Vine shoots. Staking pot Vines and Peas. Preparing land for Scarlet Runners. Earthing-up Cucumbers and well watering them. Tying up more Lettuces. Watering Hamburg Vine borders. Weeding and cleaning Asparagus beds, and manuring inside late Vine border.

May 11.—Potting Heliotropes in 4½-in. pots for summer blooming; potting off Tuberoses, Marjoram, and Sweet Basil; also young Cyclamens, and Vine eyes. Sowing another batch of Balsams, Mignonette, Mustard and Cress, and Chervil. Putting in cuttings of Iresines, Justicias, *Thyracanthus*, *Panicum*, and Fuchsias. Clipping hedges, weeding Violet beds, thinning Turnips, raking land ready for sowing Peas and Beans, watering Cauliflowers, and top-dressing Lilliums. Earthing-up Broad Beans. Hoing Strawberry plantations previous to mulching them with short litter. Manuring and digging land for planting Savoys. Putting horse-droppings in Mushroom shed ready to make another bed.

May 12.—Potting off spring-struck scented Verbenas. Shifting scarlet Pelargoniums, Stocks, and *Anemone japonica* into large pots. Sowing White Stone Turnips. Making ridges ready for planting Vegetable Marrows. Watering Fig-house border. Fumigating Cucumber, Rose, Gardenia, and Stanhopea houses for green fly. Top-dressing planted-out Gardenias with loam and manure. Putting Primulas into intermediate-pits. Manuring Celery trenches. Sticking Peas and Scarlet Runners. Thinning Carrots and Turnips. Clearing Watercress beds of weeds. Cutting down remainder of old Fuchsias, and placing them in Peach-house to start into growth. Watering seed-beds with weak guano water.

Indoor Fruit Department.

Pines.—Plants of these that started early in winter will now be ripening off their fruit; therefore withhold water when colouring takes place, if the soil about their roots be in proper condition. At this stage of growth, if the room be wanted for others, they may be removed to a Vinery in which Grapes are ripening. Plants started at the beginning of this year will be swelling their fruit fast, and should have a night temperature of from 70° to 75°, according to the state of the weather, with a bottom-heat of from 85° to 90°; maintain a high temperature by day where sharp forcing is requisite, giving air early on fine days, and shutting up so as to derive as much benefit from the sun as possible, and allowing a temperature of 90° when available in the afternoon. Sprinkle overhead through a fine rose, but avoid heavy syringing; damp all available surfaces, and keep up an amount of moisture corresponding to the temperature required, without the free use of the evaporation troughs at this dull season. Plants at this stage will require careful attention as regards watering; keep them in a free-growing, moist state at the roots; examine them weekly, and do not withhold water until colouring

takes place. Succession Pines potted as before directed will now be growing fast, and should have every attention as to watering; let it, however, be done with care so as not to sour the soil. Give air early and freely in fine weather, admitting it at intervals in such a way as to prevent cold draughts, reducing it in the same manner, and shut up early with moisture sufficient to keep up a humid atmosphere. The night temperature may be allowed to fall as low as 70° before morning; the bottom-heat should be 82°.

Vines.—In some instances early Grapes are ripe and gathered, and where such occurs in the case of permanent Vines, look carefully to the condition of the border; if dry, give it a thorough watering, and well mulch it with rotten manure to prevent evaporation, well syringing occasionally to prevent spider gaining a footing. Where Grapes are swelling off, shut up early in the afternoon, taking all due advantage of the sun's rays, and maintaining humidity in keeping with the clearness of the atmosphere outside. If red spider exist, advert to hand-sponging as the best means of getting rid of it; where front air is carefully and judiciously used, it seldom makes its appearance if all due attention be paid to watering and shutting up. Houses started two months ago will require every attention as to stopping, tying, and the regulation of the shoots. Good foliage being of the greatest importance, encourage main leaves by allowing the side shoots to run to the next Vine, or say 3 ft., which will be in some respects more than equal to being stopped three leaves beyond the bunch with lateral leaves. At all times a fixed system should be followed, and pinching done in an early stage of growth, so as to allow of the finger and thumb doing the necessary work. Look over weekly, and rub out growths not wanted; see to the thinning of the bunches as soon as the berries begin to swell; avoid over-thinning in the first instance before the nature of the bunch can be fully realized, it being better to revert to it again. Water freely during this active state of growth; where inside borders are playing an important part, with a thorough drainage over-watering with tepid water is almost impossible. During dull weather, where the heat is kept up by hard firing, avoid the free use of the evaporation troughs, which tend to induce warts, of which the Vine is so susceptible. Allow Hamburgs a night temperature of 65° after they have pushed their buds freely, and Muscats 70°, with an increase while in bloom. Treat Lady Downes and other late sorts as Muscats at this particular stage.

Peaches and Nectarines.—Houses started in November will now be ripening their fruit; any foliage obstructing the sun's rays should therefore be pushed aside. A somewhat drier atmosphere should also be maintained with a freer circulation of air given gradually, so that no check may take place. If the young wood show no signs of grossness, let the border have a top-dressing of decayed manure, if not already done, and be well watered. If for any reason the border has been kept drier through the growing season than is usually the case, withhold water at this period, otherwise splitting will occur, and render the fruit of little value. In succession-houses tie in the young wood, allowing it to be fully exposed and well ripened, which goes a long way towards ensuring next year's crop; thin the fruit by degrees, and ward off green fly by means of Tobacco-smoke, and spider and thrips by a free use of the syringe. Trees growing grossly should be allowed to bear a heavy crop; rub off all front and back shoots, shut up with sun-heat where necessary to push on growth, syringe freely, and maintain a night temperature of 60° before stoning takes place; after that 5° more may be allowed.

Figs.—These, like other fruits when ripening, are benefited by a somewhat dry atmosphere, which greatly assists the flavour. Plants in pots at times can be removed to a drier house, but when planted out in a Fig-house, that cannot be done. Well water the borders after the first crop is gathered; also mulch and well water pot-plants with manure-water. Thin crops thickly set, for if allowed to remain too long unthinned, more dropping of fruit takes place than need be.

Strawberries.—Continue to forward succession batches of these according to the demand. They do better now in pits or frame than in houses in which other occupants require artificial heat. Thin out the fruit as early as possible after it is set. If they be allowed to stand and ripen it off where they set it, place them on turves with the grassy side down, a condition which greatly assists the swelling and colouring, and suits the end in view much better than saucers. Retard early crops where necessary by moving the plants into a cold-house or pit just before colouring takes place. If red spider make its appearance on Strawberries in Vineries, it must be at once removed.—J. HUNTER, *Lambton Castle*.

Watts' Excelsior Broccoli.—This is an excellent mid-season variety; when sown in the middle of May, and planted after Potatoes, the plants do not grow to a great size, and the objectionable large stalk is thus obviated. When the heads are as large as a tea-cup, they may be cut for table.—R. GILBERT, *Burghley*.

TREES AND SHRUBS.

REMARKABLE HARDY SHRUBS IN WICKLOW.

WHEN recently examining a very interesting collection of hardy shrubs belonging to a friend in the county of Wicklow, I was much struck with the extraordinary appearance of a very fine and well-grown specimen of that most curious and rare tree, the Cockscomb Ash, which I had never before seen, and of a branch of which the accompanying woodcut gives an accurate and faithful representation. The tree was purchased about forty years ago when about 1 ft. high from an Irish nurseryman, and is grafted on the common Ash. Its present height is 10 ft. 9 in., girth of stem at the junction of the graft, 22 in., and circumference of the branches, 34 ft. It was moved to its present position when about 4 ft. high, and is growing in rich, deep, well-drained loam. The beautiful

Branch of Cockscomb Ash.

little Mayflower of Canada (*Epigaea repens*), so difficult to manage or get to bloom in this country, was also in flower, planted on a raised and well-drained bed of black peat-mould in a shady corner of the garden. If this pretty pale bluish-flowered, Hawthorn-scented little hardy trailer could once be got to acclimatize itself in our peaty woods, it would be a most desirable acquisition. I here also saw for the first time in this country the *Ruscus aculeatus* or Butcher's Broom, pretty freely covered with its handsome bright scarlet berries produced so curiously from the centres of the leaves; so conspicuous and ornamental are these berries, which resemble those of the *Solanum capsicastrum* but of a much deeper shade of red, that in the South of France where the plant produces fruit freely, and where Holly berries are exceedingly scarce, it is largely used by English people wintering abroad for Christmas decoration, and forms an admirable substitute for the Holly. Why it does not generally produce its handsome fruit in Ireland, where it otherwise seems to flourish so admirably, I am at a

loss to understand. I here also recognized the identity (a circumstance which had some time ago been brought under my notice by a nurseryman in the North of Ireland) existing between *Eurybia parviflora* and the shrub sent out a year or two ago under the new name of *Olearia Haastii*, my friend having a large bush which he had had for many years under the former name, and also a small plant which he had recently received as a new hardy shrub under the latter name. W. E. G.

ORNAMENTAL CHERRIES.

In the genus *Cerasus* we have a large group of species and varieties of evergreen and deciduous trees and shrubs, very dissimilar in general appearance and habit of growth. They are indigenous to Europe, Asia, and America, and with few exceptions, hardy enough to withstand our severest winters in the open air. Several of the species have been long in cultivation, and are still among the best known and most prominent of the trees and shrubs which adorn our parks and pleasure grounds. To this genus belong the Bay and Portugal Laurels—themselves the grandest and most useful of our hardy evergreens—while the no less ornamental Cherries, apart from their importance as fruit-bearers, are favourably known as being among the finest of our deciduous flowering trees. Of the species in cultivation, the most useful for decorative purposes are the following:—

The Gean or Wild Cherry (*Cerasus Avium*), sometimes called *C. sylvestris*, is a bushy, deciduous tree, growing to a height of from 30 ft. to 40 ft. It is a native of Britain and several other countries in Europe and Northern Asia. The flowers, which are pure white and produced in bunches from the sides of the shoots, are generally very abundant, and expand in April. The wood being hard, close-grained, and of a fine reddish colour—resembling, when polished, some of the varieties of Mahogany—is employed by cabinet makers in some of their finest work. Besides its importance as an ornamental tree, the Gean is interesting as being one of the parents of a long list of fruit-bearing varieties, obtained by hybridizing with the Common Cherry (*C. vulgaris*). The Wild Cherry has been freely introduced into our parks and ornamental plantations, where its handsome habit of growth, elegant foliage, and the great profusion of its showy blossoms, render it a popular favourite. Though by no means particular in regard to soils, it is always seen in greatest perfection in such as are light and porous, and produces its flowers most abundantly in a sunny aspect.

DOUBLE-FLOWERED GEAN (*C. Avium*, fl.-pl.).—When in bloom, this form is even more effective than the parent, the large double flowers being produced in great profusion, while the tree is of a comparatively small size. Having a somewhat dwarfer habit of growth, the result probably being propagated by grafting, it is admirably adapted for planting in shrubberies, or as a single specimen on a lawn.

The Common Cherry (*C. vulgaris*).—This is a bushy, deciduous tree, of from 25 ft. to 30 ft. in height; it is indigenous to the temperate parts of Continental Europe, and probably, also, to Britain, where, though not now found in a wild state, it has been cultivated from a remote period; the leaves are of an ovate-lanceolate form, serrated, and of a bright, glossy green colour; the flowers, which expand in April and May, are snowy-white, and have a splendid effect when in perfection. As an ornamental tree, the Cherry occupies very much the same position as the Gean, which it resembles so closely in foliage, flowers, and general appearance, that some are of opinion that though distinct enough for popular identification, they should be included in one species. In addition to the large number of varieties of this species cultivated for their delicious fruit, there are several others highly esteemed as decorative trees, and of these the following are the most distinct and desirable:

DOUBLE-FLOWERED CHERRY (*C. vulgaris* fl.-pl.).—This forms a neat, moderate-sized tree. When covered with its clusters of pure white, Daisy-like blossoms, it is an object of singular beauty.

FRENCH CHERRY (*C. v. gallica*).—This has large, white semi-double flowers, produced in remarkable abundance; it has a more compact, pyramidal habit of growth than the species, and is much valued as a lawn or park tree.

ACUBA-LEAVED CHERRY (*C. v. acubæfolia*).—This differs chiefly from the type in its leaves being beautifully blotched, rendering it very effective as a contrast to the dark greens of most of the other deciduous ornamental trees.

TOBACCO-LEAVED CHERRY (*C. v. nicotianæfolia*).—This has much larger leaves than any of the other sorts. They are of a deep, shiny

green, and, like those of the species, serrated. It forms a dense and very symmetrical tree, well deserving a prominent situation.

The Bird Cherry (*C. Padus*).—This is a broad, bushy, deciduous tree, of from 20 ft. to 40 ft. in height; indigenous, and also found wild in Central and Northern Europe; the leaves are of an ovate-lanceolate form, serrated, and of a warm, green tint, assuming as they decay a reddish colour, and, when bruised, have a pleasant odour; the flowers are individually small, but being borne in long drooping racemes are very showy; they are pure white, and generally in perfection in May. The fruit, which in most seasons is very abundant, is ripe in July, and though not tempting to the human palate, is greedily devoured by most of the small birds; hence the popular name Bird Cherry. It is, as it richly deserves to be, a great favourite in our ornamental grounds, forming as it does an exceedingly handsome specimen tree, and well adapted for associating with others in mixed plantations. There are several varieties in cultivation, of which the following are the most distinct:

ACUBA-LEAVED BIRD CHERRY (*C. P. acubæfolia*).—This differs only from the species in its leaves having a bright, golden variegation; it is a fine lawn or shrubbery tree.

DOUBLE-FLOWERED BIRD CHERRY (*C. P. fl.-pl.*).—A remarkably pretty sort, with double flowers produced in great profusion; it is somewhat dwarfer than the parent.

GLAUCCOUS-LEAVED BIRD CHERRY (*C. P. glaucifolia*).—This variety is valued for its shining foliage; of a peculiar, light green foliage. The flowers are similar to those of the species.

BROAD-LEAVED BIRD CHERRY (*C. P. latifolia*).—This is worthy of introduction into ornamental plantations for its large and handsome foliage.

The Perfumed Cherry (*C. Mahaleb*) is a deciduous shrub or low tree, indigenous to Central and Northern Europe, particularly to France and Switzerland, where in mountainous districts it occurs in great abundance, forming a densely-branched bush of from 15 ft. to 20 ft. in height. It has been cultivated in British gardens since 1714. In the countries where it abounds the wood is much sought after for fancy cabinet work, as, in addition to its excellent quality and its capability for receiving a brilliant polish, it has an agreeable perfume. The bark is smooth and of a pleasing whitish-gray colour, quite distinct from that of any of the other sorts. The leaves are ovate, sharp-pointed, slightly scented, and of a pale lead, green tint. The flowers, which are pure white and strongly scented, are produced in roundish racemes from the sides of the branches. They expand in April or May, and are succeeded by small black drupes or berries which ripen in July, which, though by no means palatable to man, afford a rich feast to fruit-eating birds. This species is sometimes employed as a stock on which to graft the edible Cherries, the object being to dwarf the plants, and to induce precocious fruit-bearing, rendering them handy for pot culture under glass. If less showy so far as regards flowers than some of its congeners, and not now so commonly met with as it was half a century ago, the Mahaleb is nevertheless a pretty tree, well suited, from its handsome habit of growth and elegant warm, green foliage, for blending in ornamental plantations with others of more sombre tints, and, as it thrives in poor gravelly and dry calcareous soils, it might with advantage be much more utilised than it is for clothing banks and similar situations where few shrubs and trees would find sustenance. The following varieties are popular among admirers of decorative trees:—

WEeping PERFUMED CHERRY (*C. M. pendula*).—This variety has weeping branches, and when grafted on stocks of the common Gean about 5 ft. high, it forms a neat specimen, useful for a small lawn, the centre of a flower-garden bed, or an open position in the shrubbery.

VARIEGATED PERFUMED CHERRY (*C. M. variegata*).—This has leaves prominently blotched and margined with light yellow or straw colour. It grows quite as freely as the parent, and its variegation is always best developed in a sandy, rocky soil, and in an exposed sunny aspect.

The Virginian Bird Cherry (*C. virginiana*).—This is indigenous to Virginia, to several of the United States, and also to some of the milder parts of Canada, where it forms a stately tree of from 50 ft. to 80 ft. in height, with long, wiry, drooping branches. It has been cultivated in our ornamental plantations since 1724. The leaves are oblong, tapering to a sharp point, serrated, and smooth glossy green. The flowers, which are pure white, are borne in long racemes from the sides of the branches; they expand in May, and are in most seasons very abundant, and in milder districts are succeeded by small red berries. In this country the Virginian Bird Cherry is generally seen as a low tree with somewhat drooping branches, never attaining those lofty heights which render it such a

conspicuous object in the landscape, and so valuable for its timber, in some of its warmer natural habitats. It is, however, none the less important for decorative purposes, and deserves to be much more extensively planted than it has hitherto been. A rich, dry soil, and a moderately sheltered situation are essential to its well-being.—“Gardener.”

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

MAY 2.

THIS exhibition was in every way an excellent one, the productions of all kinds shown being greatly in advance of anything seen at South Kensington for some years past, and the Queen's visit invested the occasion with additional interest. The Orchids and other rare plants contributed by Messrs Veitch & Son were of a very superior description, as were also the new plants and Cycads from Mr. Bull's collection. Mr. B. S. Williams, Messrs. Rollisson, and other nurserymen, also contributed effective groups of new decorative plants. Rhododendrons and Roses in excellent condition were furnished by Messrs. Lane and by Messrs. Paul and Son. Hardy flowers were shown by several growers, Mr. Dean's Forget-me-nots and Japan Primroses being greatly admired, while the collection of Daffodils, Jonquils, and other Narcissi, sent by Messrs. Barr & Sugden, was the largest and most perfect ever exhibited, containing, as it did, over 100 distinct varieties.

First-class Certificates.—These were awarded to the following new and rare plants:—

***Coleus multicolor* (Veitch).**—A distinct variety, with crimson or flame-coloured ovate leaves, deeply cut along the margins. It appears to grow freely, and may be useful as a decorative, fine-foliated plant. It comes from the Solomon Isles.

H. P. Rose Emily Laxton (Paul & Son).—A free-growing English seedling, bearing full bold flowers, the petals of which are well rounded and smooth in outline, and the colour is a rich, rosy-carmine, the older flowers being suffused with purple.

***Lomaria discolor pinnatifida* (Veitch).**—An elegant Fern often assuming a sub-arborescent habit, and bearing an ample crown of feathery, slightly-erected fronds of a peculiarly pleasing bright green tint. It is one of the most distinct of all the smaller *Lomarias*, and is well worth culture.

***Anthurium Browni* (Veitch).**—A robust-growing Aroid, with gigantic, dark green leaves nearly 1 yard in length and 2 ft. in diameter, borne on long arching petioles, useful as a stove, fine-foliated plant, and distinct from all other species in cultivation.

***Dracæna, Mrs Bause* (Wills).**—A compact-habited plant, having gracefully-disposed and brightly-coloured foliage: useful for decorative purposes, or as a dinner-table plant.

***Alpine Auricula, John Ball* (Turner).**—A strong-growing free-blooming seedling, having a clear rich golden centre surrounded with a bold border coloured like crimson velvet.

***Alpine Auricula, Florence* (J. Douglas).**—A very showy variety, large in size, and having golden paste, the body-colour being rich blackish-crimson: well worth culture either for decorative purposes or as an exhibition variety.

***Alpine Auricula, Prince* (Douglas).**—A large-flowered variety, similar to the last in form, but of a distinct blackish-purple colour.

***Self Auricula, Sarah* (Turner).**—A showy, free-growing variety bearing a good truss of smooth, circular flowers. The paste is dense and pure, the body-colour being of a rich violet-purple.

***Agave Schidigera princeps* (W. B. Kellock).**—A remarkably perfect and distinct variety of the filiferous American Aloe, the stout, dark green, dagger-shaped leaves being marked with white, and having whitish marginal filaments.

***New Zamias* (W. Bull).**—In the large collection of Cycads sent by Mr. Bull, were three varieties, to which first-class certificates were awarded, namely, *Z. Roezli*, *Z. obliqua*, and *Z. Lindenii*, all graceful plants, having broad bright green leaves on slender, arching stems. In habit these differ greatly from the kinds commonly cultivated, and when plentiful they will be noticeable as decorative garden plants.

***Pelargonium Empress of India* (Sweet).**—A distinct and showy variety, admirably adapted for decorative purposes.

***Aralia filicifolia* (B. S. Williams).**—A graceful stove shrub, having elegantly-cut foliage, and well adapted for decorative purposes, or as a dinner-table plant.

***Adiantum Williamsi* (B. S. Williams).**—An elegant, free-growing Maiden-hair Fern, having arching, tripinnate fronds 15 in. or more in length, the semi-lunate pinnae, being of a fresh Apple-green tint, and seemingly dentate around their margins.

***Cineraria, Mrs Beck* (Mr. James).**—A compact-habited plant, having circular flowers of large size, the petals of which are broad and of a dark velvety purple colour.

***Zygopetalum Clayi* (Clay).**—A free-growing hybrid plant, raised by Lieut. Colonel Clay, Wallasley, near Birkenhead. It is intermediate between *Z. maxillare* and *Z. crinitum*, and is quite distinct from *Z. Sedeni*, which is also an hybrid plant, and the result of a similar cross. The plant in question is similar to, but stronger in habit than *Z. maxillare*, and bears a five or six-flowered spike of brown-sepalled, purple lipped flowers, each bloom being about 3 in. in diameter.

***Hydrangea Thomas Hogg* (Veitch).**

Orchids.—These were well represented by large and varied groups from nearly all the principal growers, including Sir Trevor Lawrence, Messrs. Veitch & Sons, Mr. W. Bull, Mr. W. Terry, Mr. J. W. Miles, and others. Messrs. Veitch & Sons had well-bloomed plants of *Oncidium varicosum* and its allies *O. Forbesi*, *O. Marshallianum*, and the delicate lemon-yellow tinted *O. concolor*. *O. Cressus* is another distinct and effective little Orchid well worth careful culture. A pan of the snowy-white *Cypripedium nevium* bore about twenty flowers and buds. *Cattleya intermedia*, and the vivid carmine *C. Skinneri* were also very effective. Among new hybrid Orchids in this collection we noted the orange-coloured *Lælia flammea* and several *Lady's-slippers*, including *Cypripedium vexillarium*, *C. Harrisonianum*, *C. Argus*, a distinct profusely spotted kind from the Philippine Islands and others. This group was tastefully arranged, Palms and other fine-foliated plants forming a good background to it, and in front were a few delicately-tinted new *Gloxinias*, while several rare kinds of *Nepenthes* were intermixed among the Orchids with excellent effect. Sir Trevor Lawrence sent a remarkably well-grown collection, among which were three well-flowered specimens of *Cypripedium caudatum*, each bearing five large flowers; a strong plant of *Oncidium varicosum*, bearing a three-branched spike, on which were some five flowers, each being more than 2 in. across. A large plant of the ivory-white *Epidendrum bicoloratum* bore five strong spikes, on one of which we counted twelve or fourteen flowers and buds. The comparatively scarce *Oncidium Marshallianum* was represented by one of the finest examples ever exhibited; it bore three stout, branched spikes, on which there were about 100 large and richly-coloured blooms. *Cattleya labiata* bore six fine flowers, and there were in addition some well-bloomed *Lady's-slippers*, *Dendrobies*, and a richly-coloured variety of the old but valuable *Cattleya Skinneri*. Mr. Ollerhead, gardener to Sir H. Peck, of Wimbledon House, sent a small plant of *Masdevallia Harryana*, bearing sixteen flowers and buds, the former being very circular and of a rich carmine tint. Two other examples of the last-named plant shown, although not so floriferous, were distinct and effective. Mr. W. Bull had also a pretty group of Orchids, in which we noted several good forms of the golden-brown blotched *Odontoglossum triplianum* and *Phalænopsis Luddemanniana*; *Masdevallia Lindenii* was also represented by a well-grown specimen; other good plants were *Cypripedium nevium*, *C. caudatum* (bearing ten long-tailed flowers), and others. Mr. C. E. Shea, Foot's Cray, had an excellent specimen of *Phalænopsis amabilis*, bearing ten flowers and seven or eight buds on a long, drooping spike; the individual flowers measured 4½ in. in diameter, and the petals were of great substance and well rounded. Among other remarkable Orchids exhibited at this show we also noticed a well-bloomed specimen of *Dendrobium tortile roseum*, an old plant, but one now rarely seen in good condition. Mr. J. W. Miles, of Shirehampton, Bristol, had a very fine specimen of the rare *Odontoglossum Phalænopsis*, having fully 100 expanded flowers; *Cattleya Skinneri*, with eight good spikes; *Oncidium macranthum*, with twenty or thirty flowers on a long flexuose spike; and also well-bloomed examples of *Phalænopsis Schilleriana* and *Odontoglossum Pescatorei*. Mr. Roberts, gardener to Mr. Terry, had a well-coloured variety of *Cattleya Mendellii* and *Dendrobium litidlorum*. A large and well-bloomed plant of a late-blooming variety of *Coelogyne cristata* came from Mr. Stevens, of Trentham; and Mr. P. Moore sent a group of well-grown plants from the gardens at Blindon Hall.

Miscellaneous Decorative Plants.—A tastefully-arranged group of Rhododendrons, cut-leaved Japanese Maples, and orange and yellow-flowered hardy Azaleas, came from Messrs. Veitch & Son's, Coombe Wood Nurseries, at Kingston. This collection was one of the most pleasing in the Show, the vivid colours being carefully toned down by green, purple, and brown foliage. Messrs. Osborn & Sons sent an excellent and well-arranged group of dark pinnate-leaved Palms, *Pandanus Veitchii*, crimson-leaved *Dracænas*, and one or two distinct fine-leaved plants, seldom seen exhibited, such as *Oreopanax dactylifolia*, with bold lobed foliage; *Aralia leptophylla undulata*, with digitate pale green leaves, and the bright green windmill-leaved Palm (*Licuala horrida*), beside which the scarlet-spathed *Anthurium* shone out with excellent effect. Mr. Wills, sent about 100 plants of his new hybrid and seedling *Dracænas*, among which we noted the compact and vigorous-habited *D. Mrs. Wills* sturdy plants, from 12 in. to 15 in. in height, each bearing about thirty leaves, from 8 in. to 10 in. in length, and of a bright green colour, boldly striped and margined with white; *D. Mrs. Bausé*, a dwarf, slender-leaved plant, highly coloured, and excellent for decorative purposes. This received a first-class certificate. The free-growing, white, variegated *D. terminalis alba* was also well represented. This splendid group of seedling *Dracænas*, raised by Mr. Wills' manager, M. Bausé, is a striking instance of the value of careful cross-breeding. A very remarkable collection of Cycads came from Mr. W. Bull, the most distinct being *Enecephalartos cycadifolius*; *E. horridus*, also a distinct spinose kind, with gracefully-arched, glaucous foliage; *Zamia Roezli*, to which a first-class certificate was awarded, and which differs from its compeers in having very broad leaflets and slender stems; *Z. obliqua*, and *Z. Lindenii*, both of which received first-class certificates, and both distinct

broad-leaved kinds, having very bright green leaflets. The distinct habits and permanent foliage of these plants render them peculiarly desirable for conservatory decoration. A very effective group of stove and greenhouse plants came from Messrs. Charles Lee & Sons, Hammer-smith. Messrs. James Carter & Co. contributed a large miscellaneous group, consisting of Crotons, Pandanads, cut-leaved Japanese *Acer variegata*, New Zealand Flax, and slender-leaved Palms of various kinds. Messrs. Cutlisch & Son, Highgate, showed a well-grown group of hard-wooded plants, Palms, Rhododendrons, and a new bluish-white Tulip, all in excellent condition. Mr. Ratty, gardener to A. Thornton, Esq., The Hoe, Sydenham, had a well-bloomed group of Azaleas, among which we noted Leonie Van Houtte, a large, white-flowered variety; Criterion, blush-spotted; Neptune, scarlet; and Roi des Blancs, a capital white-flowered kind. Messrs. Paul & Son, Cheshunt, furnished a large and well-bloomed group of pot Roses, as well as an extensive and varied collection of cut blooms. Amongst the plants in this group the most distinct were *Centifolia rosea*, blush; *alba rosea*, white; Mme. Lacharme, the new white Hybrid Perpetual; and Captain Christy, blush. A plant of the delicate rosy La France in this collection was noticeable, bearing, as it did, sixteen or eighteen fine blooms. Messrs. Lane & Son, Berkhamsted, sent a beautiful and floriferous group of pot Roses, conspicuous among which were Beauty of Waltham, crimson; John Keynes, velvety crimson; Catherine Guillot, bright fiery rose; and the delicate reflexed Comtesse de Serouye, peach. Messrs. Lane also sent a well-flowered batch of early-flowering Rhododendrons; and an interesting collection of dwarf and grafted succulents came from Messrs. Croucher & Boller, 73, South Row, Keusal New Town. One of the most distinct plants in this collection was a specimen of the grey-haired "Old Man" Cactus (*Pilocereus senilis*). Mr. B. S. Williams contributed a large bank of new and rare Orchids, stove and greenhouse flowering plants, fine-leaved plants and Ferns in great variety. Messrs. Veitch & Son contributed a basketful of the new white-flowered Hydrangea named Thomas Hogg, a kind quite as vigorous and fully as floriferous as the common species, of which it is a distinct and valuable form, its immense heads of flowers being of a paper-white colour. This received a first-class certificate, as did also the majestic Aroid Anthurium Browni. Mr. J. H. Ley sent a well-grown miscellaneous group of Palms, Ferns, and other fine-foliaged plants, also his curious new Fern *Pteris serrulate* Leyii. Messrs. F. & A. Smith, Dulwich, had a well-bloomed lot of white, crimson, purple, and scarlet Azaleas; and a well-grown collection of large-flowered *Calceolarias* and richly-coloured *Cyclamens* and *Cinerarias*, came from Mr. James, Isleworth; well-bloomed seedling, and named *Gloxinias* came from Mr. F. K. Kingborn, Richmond. Among these were interspersed little plants of the elegant and singular-habited *Reidia glaucescens*, and graceful Palms of different kinds. Mr. J. Laing, Forest Hill, showed a large and varied bank of Azaleas and fine-foliaged plants, among which were several new forms of *Colens* and *Caladiums*, and slender-leaved *Aralias*. Mr. H. Coppin, Shirley, near Croydon, contributed a batch of well-grown Zonal and Tricolor Pelargoniums. One of the most attractive miscellaneous collections of decorative plants in the exhibition came from Messrs. J. Standish & Co., Ascot, who had double-flowered Azaleas, *Ericas*, *Cinerarias*, and fragrant Carnations, these being set in a bed of the filmy *Adiantum gracillimum*, and backed up by Palms and *Dracenas* of various kinds. Messrs. Rollisson & Sons had a splendid collection of Azaleas, among which we noted Marie Van Houtte, delicate semi-double white; President Ghellinck de Walle, crimson; and Comtesse Eugene de Kerchoue, white flaked with scarlet, as being desirable and distinct kinds. Mr. Charles Turner, Slough, also showed a well-arranged group of Azaleas and Palms, and in front of this group a treble row of choice show self and Alpine Auriculas. A very handsome group of large-flowered Clematises came from Messrs. George Jackman & Son, Woking, and among the kinds shown we noted C. Countess of Lovelace, a distinct and vigorous lilac-purple, double-flowered variety; also Vesta, with compact eight-sepalled flowers of snowy whiteness; Mrs. Baker, Maiden's Blush, The Queen, and Stella are also floriferous and desirable kinds for pot culture. Mr. J. Aldous, Gloucester Road, South Kensington, showed a well-arranged group of red-leaved *Dracenas*, *Pteris*, and other Ferns, among which the graceful Palm-like *Cureuligo recurvata* was introduced with excellent effect.

Hardy Flowers.—Of these a charming group came from Mr. Roberts, gardener at Peterborough House, Fulham. Among them we noted the white Wood Lily (*Trillium grandiflorum*), Poet's Narcissus, Veitch's Primrose (*Primula cortusoides amena*), the golden star-flowered *Doronicum austriacum*, Bluebells of various kinds, and also *Polyanthuses*. *Pæonia humilis* is a distinct single variety with crimson petals, well worth pot culture; white-flowered *Candytufts* of various sorts, and Solomon's Seal were also shown in good condition, and much admired. Mr. Candwell, Wallingford, sent a well-grown group of seedling *Polyanthuses*, including crimson, purple, yellow, and fancy variegated or parti-coloured kinds. Messrs. Barr & Sugden, King Street, Covent Garden, showed a collection of Narcissus flowers, comprising over 100 distinct sorts, some of which were very showy. Among them were a quantity of new seedling forms and several of the older kinds now very rarely seen in cultivation. Mr. R. Dean furnished a lovely group of Forget-me-nots and Daisies of various colours, together with golden and crimson-flowered Wallflowers, and some cut-petalled and distinct-coloured forms of Veitch's Japan Primrose. Some distinct laced Auriculas belonging to the Alpine section were much admired in this group. Mr. H. Parr, The Gardeus, Harrow Weald Park, sent twenty-four gold-laced *Polyanthuses*. Messrs. Brooke & Gallop again contributed specimens of their new spiral Mignonette, a kind large in size, and exquisite as regards odour. The specimens

shown were grown in 6-in. pots, and bore from six to ten large spikes of flower, associated with fresh and healthy foliage, also of large size. Mr. H. J. Elwes sent cut flowers of *Gladiolus insignis*, a scarlet-flowered plant from the Cape of Good Hope, likely to prove useful as a winter-blooming decorative plant; also a flower of a new Iris, seemingly intermediate between *I. susiana* and *I. iberica*, its ash-grey, speckled flowers being 5 in. or 6 in. in diameter. The same exhibitor also sent five wild species of Tulips from various parts of the Levant: these were Tulipa Eichleri, T. Haageri, T. Clusiana, T. fragrans, and T. Orphanides. A pan containing three forms of the hardy North American *Cyrtopodium acule*, remarkably well grown, also came from Mr. Elwes: one form had very broad foliage and very large but pallid flowers on long, flexuose scapes; another had flowers and leaves of medium size, but of a rosy-crimson tint; while a third, similar to the last in habit and size of flower, bore pale-tinted blossoms. The plants were in the most vigorous health; indeed, we never saw this Lady's-slipper so vigorous before. Mr. J. Wills sent an admirably arranged group of slender-stemmed Palms and flowering plants of various kinds, in addition to a tasteful plateau of fresh living Moss, on which were disposed soft yellow and blush Rose-buds, and the gracefully arching spikes of *Phalenopsis Schilleriana*, the whole being flanked by choice Palms and Pitcher-plants of various kinds.

Floral Decorations.—These were well represented, some of the arrangements being remarkably bright and effective, but the sameness of form, and in some cases grouping, prevented our enjoying them so much as could have been wished. If we want to buy a graceful group of flowers we must perforce have a pyramidal one for the coat, and a more or less Mushroom-shaped one for a bouquet, nor are dinner table decorations a whit more variable; we get different flowers and a strange mixture of colours sometimes; it is true, but even the best of our floral decorators have not yet learnt that symmetry and artistic taste are not synonymous; the reverse of this often being more strictly true. In the dinner table decorations Mr. C. Burley, of Brentwood, was first with an arrangement consisting of three March stands lightly filled with Maiden-hair Fern, the scarlet and white flowers of *Clerodendron Balfourii*, blue *Cineraria* blooms, pink and white *Fuchsias*, and pink *Rhodanthe*, the bases of the stands being hidden in a mass of feathery Fern fronds, white Arum Lilies, and Pink Roses with Azaleas, and a few smaller flowers here and there. The extreme lightness of the two upper tiers in Mr. Burley's stands was due to their edges being fringed with the Pampas Grass slit into extremely narrow thread-like pieces. Mr. J. Aldous who was second in this class, had a really distinct and novel arrangement, consisting of seven low March stands which we recommend him to repeat substituting a Cocos or other graceful Palms for the central and largest stand, so as to break up the monotony which was evident on this occasion. The flowers employed in this decoration were pink and white *Pelargoniums*, white Japanese *Spiraea*, Lily of the Valley, *Deutzia*, *Eucharis*, and others, enshrouded in a light filmy haze of Maiden-hair Fern and *Isolepis gracilis*. Messrs. Pounce & Son, who obtained the third award, had a good arrangement; as had also Mr. J. Hudson, whose two March stands were very artistically filled, the weakest point being the central Palm, which was scarcely striking enough for such a position. About thirty bouquets of various kinds were exhibited, besides crosses, wreaths, and button-hole flowers in profusion. The best bouquet came from Mr. Bromwich, of the Buckingham Palace Road, who had one of the most tasteful ball-room arrangements which we have yet seen. It consisted of a perfect white *Camellia* as a centre, around which were tastefully disposed Moss, Tea-scented, and other Roses, pearly *Stephanotis*, *Bouvardias*, Lily of the Valley, and other choice flowers, the whole being fringed with Fairy Rose-buds and leaves, with here and there a delicate gariture of Fern. The same exhibitor also had other tasteful floral arrangements, including a novel Court bouquet, in which the different shaded kinds of yellow, buff, and pale orange Orchids and Tea Rose-buds were toned down by gossamer-like Ferns. Mr. Buck, of Covent Garden, had a beautiful bridal bouquet; Messrs. Wood, Parmely, & Co., Albert Gate, being third; and Mr. Stone, Covent Garden, fourth, with fairly good examples of the bouquetist's art.

Miscellaneous Fruits and Vegetables.—Mr. Haycock, gardener to R. Leigh, Esq., Barham Court, sent a good dish of James Veitch Strawberry and three brace of Cooling's King of the Cucumbers, a long, shapely, white-spined variety. Mr. G. T. Miles, gardener to Lord Carington, showed three remarkably perfect Jamaica Pine-apples and a Golden Melon. Mr. Cox, gardener to Earl Beauchamp, furnished six large Citrons of home growth. Mr. Batters sent a good dish of McLean's Little Gem Peas grown in 8-in. pots on shelves in a cool house. Mr. Pince, Cookham, contributed a dish of highly coloured Sir J. Paxton Strawberries. Mr. Wildsmith, gardener to Visct. Eversley, Heckfield, sent excellent samples of Anguste Nicaise; and Mr. Hudson, gardener at Gunnersbury House, showed a good dish of President Strawberry. Mr. Stevens, of Trentham, furnished a large branch of early forced black Cherries, and also a dish of the Black Heart and Bigarreau varieties. A variegated-leaved Cauliflower came from Mr. W. Horley, Toddington, Beds. Mr. Ollerhead, gardener to Sir H. Peck, showed a splendid dish of the fruit of the Chinese Plantain (*Musa Cavendishi*), the fruits being of very large size, and of a clear yellow colour.

Covent Garden Produce.—The collections of plants exhibited by market growers occupied both sides of the lower corridor, and formed one of the most attractive features of the show. Though somewhat formal in appearance the long lines of *Pelargoniums*, groups of *Cinerarias* and other flowering plants, received a large share of admiration from the crowds of visitors which throughout the day thronged this part of the

building. Some of the collections were arranged on stages, others on the ground, and in the latter case the effect was perhaps the best, inasmuch as every flower could be seen to the best advantage. Messrs. H. R. and G. Wright, Turner Road, Lee, contributed a well-arranged group of Palms, Dracenas, Pandanads, and Orchids, amongst which was a large and well-flowered specimen *Dendrobium eorulescens*, several good *Oncidium*s, *Odontoglossum Alexandrie*, and *Phalænopsis grandiflora*. Mr. T. C. Paget, Royal Nurseries, Clapton, showed a well-grown collection of *Spiræas*, Palms, Ferns, and Dracenas. This group occupied upwards of 90 ft. of staging, two rows of *Spiræas* were arranged at the back, next came a row of *Pteris serrulata*, in front of this were two rows of Palms (*Corypha australis*), and the front row consisted of Maiden-hair Ferns, the whole being relieved by good plants of *Dracena stricta*, *Pandanus Veitchi*, and *Pteris argyrea*. Next to this group came a collection of Show Pelargoniums from Mr. G. Braid, Winchmore Hill, who furnished examples of good culture, few of them being more than 1 ft. high, and covered with blossoms. Amongst the most conspicuous were Scarlet Gem, a good habited kind, with very large trusses of brilliant blossoms with whitish centres, the upper petals being marked with dark velvety crimson; and Duchess of Edinburgh, a very floriferous variety with white flowers delicately marked with bright red spots and stripes. This kind is something in the way of multiflorum album, but of much dwarfier and more compact habit, and the flowers are of better substance. Mr. H. B. Smith, of Ealing Dean Nursery, exhibited a collection of Tricolor and Bronze-leaved Pelargoniums, the front rows of which were embedded in Moss. These were backed up by plants of *Fuchsia Mrs. Marshall*, and all well-grown and loaded with bloom. This is the best light-flowered *Fuchsia* in cultivation for market purposes. The same exhibitor also staged an effective group of fine-foliated plants, amongst which were dwarf sturdy and well-coloured examples of *Dracena Sheperdi*, *D. terminalis*, *D. Cooperi*, *Croton Youngi*, and *Pandanus Veitchi*. These were edged with *Adiantum Parleyense* and *A. gracillimum*, between which were introduced small plants of *Pteris tremula* and *P. serrulata*, *Lycopodium formosum* and *denticulatum* laid on their sides in order to cover the pots in the front row with foliage, an arrangement which added greatly to the effect of the group. The whole were backed up by large specimens of Palms, and New Zealand Flax (*Phormium tenax*). Mr. J. Pattick, of Acton, had a mixed collection of Zonal Double, and Show Pelargoniums backed up by a row of Arum Lilies and Cannas; the front rows consisted of dwarf plants of Hydrangeas, Mignonette, Heliotropes, Coleus, and scarlet-flowered Stocks. These were in panels, by which arrangement the plants had a better effect than if they had been intermixed in a miscellaneous way. Messrs. J. & J. Hayes, of Lower Edmonton, had a large and well arranged collection, consisting of panels of scarlet Pelargoniums *Vesuvius* and *Duchess of Edinburgh*, *Eriacs depressa* and *Cavendishi*, *Fuchsias*, and Hydrangeas. These were backed up by a row of tall plants of Pelargonium Beauty of Edmonton, a brilliant crimson-flowered variety of great value for market purposes. The panels of flowers were edged with dwarf plants of the white-flowered variety of *Erica ventricosa*, *Mrs. Pollock Pelargoniums*, Fairy Roses, and Maiden-hair Ferns. The front lines were effectively broken by large plants of *Adiantum gracillimum* placed at certain intervals apart. The centre of the group consisted of scarlet Pelargoniums arranged in a semi-circle and edged with *Deutzia gracilis*. The same exhibitor also showed a large group of *Cinerarias*, edged with Fairy Roses, *Erica ventricosa*, and *Mrs. Pollock Pelargoniums*, placed alternately. Amongst the *Cinerarias* were some very dwarf-habited kinds, with well-formed flowers of rich colours. Messrs. F. H. Pounce & Sons, Hendon, had a group with a large *Lomaria gibba robusta* in the centre, and a *Dicksonia antarctica* at each end; the rest of the plants, which consisted of well-grown Pelargoniums, *Spiræas*, and *Cytisus racemosus*, were mixed together, relieved here and there by the overhanging leaves of *Dracena Cooperi*, and those of several varieties of Ferns: an edging of *Selaginella denticulata*, backed up by a row of Maiden-hair Fern, small *Lomarias*, and *Crotons*, rendered this group most effective. Messrs. Beckwith & Sons, of Tottenham, showed a group consisting of 600 Pelargoniums, which occupied a space upwards of 70 ft. in length; than these better examples of good cultivation could scarcely be imagined; they were grown in 5-in pots, and on some might have been counted as many as fifteen or twenty large trusses of bloom, and the foliage, which was of the deepest green, was produced in abundance close down to the rims of the pots. Amongst the varieties, of which there were some thirty or more, some of the best were Digby Grand, *Triomphe de St. Maude*, grande, and *Rob Roy*; the colours were skillfully distributed, and through the centre of the whole ran a row of *Duchess of Bedford*, a new white flowered Pelargonium, lately raised by Mr. Beckwith. Several plants of the same variety also formed a group in the centre; these were grown in 8-in. pots, and several of them were nearly 3 ft. through and not more than 2 ft. in height, and literally masses of blossoms. Messrs. Hawkins and Bennett, Lily Gardens, Twickenham, showed a capital collection of Zonal Pelargoniums, which were arranged in three semi-circular groups, the ends of which consisted of Madame Vaucher and Christine, the centre being filled with large bunches of cut blooms of scarlet, white, and pink kinds inserted in Moss, and edged with Maiden-hair Fern. A band of Scarlet Pelargonium *Dr. Lindley* encircled each colour, and the spaces between were filled up by plants of Maiden-hair Fern or white and pink Pelargoniums; *Isolepis gracilis* and *Selaginella denticulata* formed a good edging for this arrangement, which, though perhaps a little formal, was greatly admired. Mr. John Reeves, Acton, showed an extensive collection which occupied 120 ft. of staging; the back row consisted of large plants of Arum Lily, Palms, and standard plants of Guelder Rose. Hydrangeas and *Fuchsias* were arranged in panels edged with *Gardenias* and *Dracenas*. In the centre the letters

V. R. were formed of Lily of the Valley set in a bed of *Selaginella* and *Coleus*. Rows of show Pelargoniums from the same exhibitor were edged with Maiden-hair Ferns and Lily of the Valley placed alternately, and backed up by *Spiræas*. Mr. Reeves also staged 1000 pots of *Mignonette* of a new kind, the flowers of which are very large, while the plants do not exceed 8 in. in height. Mr. J. Seabrook, Ponder's End, showed a collection of Zonal and Show Pelargoniums and a group of *Fuchsias*. Mr. Sweet, Leyton, had a collection of flowering plants arranged that on the ground in the form of ribbon bedding; the back row consisted of *Erica persoluta alba*, in front of which were rows of Pelargonium *Triomphe de St. Maude*, *Cytisus racemosus*, *Erica colorans*, Pelargonium *Rob Roy*, *Empress of India*, and *P. Monte Christo*. In the centre was a group of Pelargonium *Empress of India*, encircled by a band of *Cytisus*, the whole being edged with *Fuchsias* and *Erica ventricosa*. Mr. Poulton, of Edmonton, had a collection of *Spiræas*, with a few pot Roses dotted amongst them, the whole being edged with Scarlet Pelargoniums and *Fuchsias*. Mr. Thomas Prestridge, of Brentford, showed boxes of Tricolor and Bronze Pelargoniums; Mr. Sawyer, of Edmonton, had a collection of *Deutzia gracilis*, Lily of the Valley, herbaceous *Calcularias*, and dwarf plants of Show Pelargoniums, arranged in panels packed up by *Thuja aurea*, *Fuchsia Mrs. Marshall*, and *Spiræas*. Mr. T. Pearce, of Hayes, showed a group of well-flowered *Eriacs* and miniature Roses; Mr. Philip Ladds, of Boxley, had Zonal Pelargoniums and *Spiræas*; Mr. Poupert, of Twickenham, sent several boxes of cut flowers as grown for Covent Garden; they consisted of *Narcissus poeticus*, *Lilacs*, Wallflowers, *Pansies*, *White Arabis*, *Hyacinths*, *Stocks*, &c.

Fruit and Vegetables.—A fine collection of fruit came from Messrs. Webber and Co., of Covent Garden; it consisted of twenty-two St. Michael's Pine-apples, *Léon le Clerc de Laval Pears*, English Apples (beautifully coloured and firm for the time of year), *Sir Charles Napier Strawberry*, and baskets of Black Hamburg and Muscat Grapes, Guernsey Figs of excellent quality, and Valencia Blood Oranges. Mr. W. Ingram, Vine Nursery, Aylesbury, showed good bunches of Black Prince Grapes, and a basket of Muscat and Black Hamburg came from the Rev. J. R. Watson, Guernsey. Mr. J. Walker, nurseryman, Thame, Oxon, exhibited a box of Mushrooms as grown on shelves and lifted in clumps; they were fine examples of growth, but discoloured through exposure to the air. Mr. W. Earley, Valentines, Ilford, contributed four dishes of dessert Apples in good condition; also a stand of Grapes, consisting of Muscats, Black Frontignan, Madresfield Court, and Black Hamburg. Two collections of vegetables were shown by Mr. Poupert, Twickenham, and Mr. Poupert, Mortlake. They consisted of excellent Seakale, bleached Asparagus, Rhubarb, Cabbage, Green Onions, Radishes, Lettuce, and Herbs. Mr. Smith, Floral Hall, Kingsland, showed two baskets of French and English Salad plants for comparison; the French quite eclipsed the English, both in quality and appearance. Amongst them were Onions, Lettuces, Endive, Dandelion (finely blanched), and Radishes. The English exhibit consisted of Endive, Lettuce, Mustard and Cress, Beet, Radishes, Tarragon, and Chervil. Mr. Mott, of Potter's Bar, showed a dozen specimens of a seedling Cucumber, raised from Improved Rabley. It has a smooth, thin skin, and is undoubtedly a good winter variety.

Miscellaneous Exhibits.—Prettily-designed specimens of colour-printing on wood, as applied to window-boxes and Palm-tubs, various sizes, were shown by Messrs. Young & Whitburn. Messrs. Fletcher, Lowndes, & Co., sent a model of a curvilinear conservatory, showing their principle of glazing with ordinary or uncured glass. Mr. Thomas, Edgware Road, showed a miscellaneous and useful collection of garden wire-work trellises, baskets, &c. Messrs. Green & Son, of Leeds, sent a large collection of their patent mowing machines and garden rollers; and Mr. Roberts, Kennedy, furnished an improved form of garden tent, easily erected, and of convenient size. A collection of useful and ornamental garden pottery came from Mr. Matthews, of Weston-super-Mare. Messrs. Waite, Burnell, Huggins, & Co., sent their new Excelsior Lawn Mowers, and Mr. F. J. Dreschler sent his seed-cleaning and measuring machinery, and also two forms of fumigating machines, both apparently effective implements.

QUESTIONS AND ANSWERS.

Green-leaved Hollies.—The two large leaves sent are from a plant unmistakably far finer than the *Ilex Sheperdi*, or *Hodgensi*, as it is also called, and the two small ones are from *Sheperdi*. Can you give me the name of the larger variety, and also that of the enclosed blooming branch of Maple?—WALTER DAWSON, *Corentry Cemetery*. [One is the Highclere Holly (*Ilex atlanticensis*), the other the Norway Maple (*Acer platanoides*).]

Peat and Loam in Italy.—I notice that much use is made in England of peat and loam. I have ascertained their names in Italian to be *torba* and *luma*, and have tried to procure these substances, but find that they are either unknown here or not used, so that it is almost impossible to get them. Can any of your subscribers tell me what I could use here as substitutes? Will they also state which are the prettiest varieties of *Hakea*?—PERRY POWERS, *Florence*.

Ferns for Room.—I should like to know if there are any Ferns that will really thrive in the air of a sitting-room without the protection of a glass.—H. E. [*Asplenium flagelliforme* is the most beautiful of all Ferns for growing in the sitting-room. The drooping fronds hang down most gracefully, each terminated by the long wire-like midrib, which is prolonged beyond the pinnae in such a singular manner. We have seen it thrive for years in the sitting-room in a window. *Nipholobolus exalustat* also does well, and we believe there are many others. Some of our readers will probably be able to advise.]

[Vol. XI.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

TREES IN LONDON.—The Duke of Westminster, whose efforts towards the opening of the squares in London deserve acknowledgment, stated the other day, while speaking of London squares at the meeting of the National Health Society, that the Plane was the only tree which would grow in towns, because it shed its bark as well as its leaves. We have several times protested against this common error. Many trees as beautiful as the Plane may be grown in London, even with its present smoky product of 5,000,000 tons of coal per annum. One of the open spaces talked of was Lincoln's Inn Fields. We have no doubt whatever, from long observation, that a whole arborescence of beautiful deciduous trees might be grown in Lincoln's Inn Fields. We shall never have beautiful squares or avenues, or planting in cities until the idea of one tree only being suitable be abandoned entirely. Why, even now, before we have begun to think seriously of planting in London in a proper manner, the Catalpas and Weeping Ashes are as healthy in the smokiest parts of London as anywhere else.

SQUARES OPEN BY TICKET.—At the meeting of the National Health Society, presided over by the Duke of Westminster on Wednesday, a well-meaning gentleman proposed to open some of the squares by ticket to the good children in schools. To those who may have seen thousands of children playing in the squares and public playgrounds of Paris, this will probably seem as wise a plan as doing out the air, or sky, or water by ticket. Better keep the dismal places shut to continue to be a monument of our narrow-mindedness and selfishness, until some succeeding generation, for very shame, will make them the ornament, and not the disgrace of London. So long as London is without any system of government, so long must we expect these and many other evils to exist. If it is to remain in the hands of the vestrymen, would it not be well to imitate the plan lately adopted by the Municipal Council of Paris, and send some of the members on a visit to other cities? Probably some of these gentlemen have never emerged far beyond the awful pall of smoke under which London is buried, and they could hardly fail to benefit by a visit to a clean and well-ordered city, where beautiful squares and playgrounds are filled with happy children.

THE GARDEN IN DRURY LANE.—Miss Octavia Hill, in her address on open spaces given on Wednesday last, defended the people from the charge of destroying the garden in Drury Lane. She had good reason to do so. In our great parks, where there is plenty of space, railings, sometimes very high, are placed round the flower-beds; here, in a contracted little spot, no such protection was given them, and consequently, when the crowds in this densely populated locality came in to see the new garden, they crowded over the edgings, but no serious injury has been done to the garden. In all such small open spaces in densely crowded neighbourhoods, what is wanted are a few well-grown trees, a gravel space, and plenty of seats. In such, with the slightest supervision, no injury could occur. Apart from the want of space and the injury from crowds to the beds, &c., the foul air in such a district as Drury Lane prevents all fine gardening, so to say. Happily, as regards the town landscapes, the shade in summer, the effect of the foliage on the air, the trees which can be grown are far more important than the flowers and shrubs, which cannot be grown in Drury Lane.

FRUIT OF STEPHANOTIS FLORIBUNDA.—I have forwarded for your inspection a fruit of the *Stephanotis floribunda*—not because I think it so very rare or curious, although many who have grown the plant for years have not had the opportunity of seeing its fruit, but because I am of opinion that some account of it in *THE GARDEN* would be interesting to many. I may add, that it has been hanging on the plant nearly twelve months.—*JOHN COCKS, Clarence Lodge, Clapham Park.* [The fruit in question, though somewhat shrivelled, measured $4\frac{1}{2}$ in. long and 7 in. round. A fruit of this plant was figured in *THE GARDEN*, Vol. VI., p. 467.]

MEDINILLA MAGNIFICA.—A plant of this, in the form of a standard, in Mr. Winsett's nursery in the King's Road, is now well furnished with large drooping clusters of rosy-pink blossoms. When grown in the shape of a bush, this *Medinilla*, when in flower, is always effective, but it is even much more so when grown as a standard. It is very

liable to the attacks of mealy bug, and some difficulty is also often experienced in propagating it; plants of it may, however, be readily struck from cuttings made of young, vigorous shoots taken off at a joint in spring, inserted in sharp sandy soil, plunged in a brisk bottom-heat, and covered with a bell-glass. Constant attention and vigorous growth constitute the only sure way of keeping the plants clear of insects, and when properly grown and well flowered, few plants better repay the trouble incurred in their cultivation than this does.—*W. S.*

ÆCHMEA MARIE REGINE.—Specimens of this are now very attractive in Mr. B. S. Williams' nursery at Holloway. The flower-spikes, which are very strong, are thickly clothed with a rosy-scarlet, bluish-tinged inflorescence, more brilliant than that of any other member of the family to which it belongs.—*S.*

DENDROBIUM CRYSTALLINUM AND TORTILE.—Specimens of each of these *Dendrobies* in Messrs. Veitch's nursery are now bearing respectively 200 fully-expanded blossoms. Plants possessing such floriferous qualities as these surely deserve more than ordinary attention.—*S.*

CHOISYA TERNATA.—Plants of this are now flowering freely in Messrs. Lee's nursery at Hammersmith, and the blossoms are agreeably scented, resembling that of the Orange. For cool greenhouses this plant is worth attention, and being nearly hardy, it may be successfully grown, even in a cold pit or frame from which frost and damp are excluded.—*S.*

RANUNCULUS BERTOLONI.—This pretty little Alpine Buttercup is now in flower in Messrs. Backhouse's nursery at York. It forms caespitose tufts close to the ground, consisting of entire, round, ornate leaves. Its flowers, which are pure white, are nearly an inch in diameter, and are borne on slender stems about 2 in. high.—*R. P.*

PLANTS IN BLOOM AT HOLLOWAY.—The plant-houses in the Victoria and Paradise nurseries are now well worth a visit; the New Holland plants, consisting, as they do, of large specimens finely in flower, are especially attractive. *Ixora Prince of Orange* and *I. Williamsi*, plants of which measure from 5 ft. to 6 ft. high and as much through, are also equally interesting, being laden with large trusses of bright orange-scarlet blossoms; *Vandas* are also finely in bloom, as are likewise *Cypripediums*, among which *C. niveum*, bearing no fewer than forty or fifty pure white flowers, was especially noticeable.—*S. C.*

ANDROSACE VILLOSA AND A. CHAMÆJASME.—These two little rock plants, which have been in lovely condition for a week or more, are now in full blossom. Both of them are very dwarf in habit, only growing about 3 in. high. *A. villosa* makes little tufts formed of rosettes of woolly leaves, from which ascend wiry stems bearing at their summits umbels of numerous white flowers with pink centres. *A. chamæjasme*, too, forms tufts, but not so compact as the former species, it having a tendency to run under the surface of the soil; the flowers of this species are white with faint yellow centres. Both kinds grow freely in good loam intermingled with small pieces of stone. It is better to keep them rather dry in winter by the protection of a projecting rock or by being placed in a cool frame.—*R. P.*

THE AMERICAN AZALEAS AT THE FULHAM NURSERIES.—The large collection of old plants of these at Messrs. Osborn's is now beginning to flower, and will be in bloom for some weeks to come. It forms one of the most beautiful sights we know of near London. The fine old varieties and species in this collection always seemed to us more beautiful in form of flower and in habit than the popular Ghent Azaleas. The plantation at Messrs. Osborn's has existed for over half a century. Mr. C. Pitman, who has long had charge of the collection of trees, first went to the Fulham Nurseries fifty-four years ago. He states that at that time some of the American Azaleas we now allude to were well-established bushes. A better testimony to their hardiness and endurance could not be desired.

AURICULAS.—At the National Auricula Show, which was held at Manchester on the 27th ult., and of which a report will be found in another column, the Rev. F. D. Horner secured nearly all the first prizes; Mr. B. Simonite, Mr. Barlow, Mr. Cooper, &c., were also successful exhibitors, Mr. Barlow being awarded a silver medal for a miscellaneous collection. The first prize for the best nine Auriculas at the Spring Exhibition of the Royal Horticultural Society of Ireland was taken by the Rev. F. Tynons with fine flowers of Superb. Turner's C. J. Perry, and Finlayson's Sir R. Peel, Mr. Leland coming next in merit with a first-rate collection.

ROSES IN POTS AT WALTHAM CROSS.—Mr. William Paul's collection of these, numbering some hundreds of plants, is now coming into bloom, and promises a fine display of flowers. Where Roses are grown so well in pots, their culture may be profitably studied on the spot.

SPRING FLOWERS AT CLIVEDEN.

MANY of our readers who have so long known Cliveden as such a charming home of spring flowers and spring-gardening will be pleased to learn that this year its beauties in this way are as remarkable as ever. As we write the Pansies, Silenes, Nemophilas, Daisies, and Forget-me-Nots, which have been greatly benefited by the few bright sunny days which we have lately had, are in great beauty. Though the colours in the different beds are all admirably arranged, formal planting has as much as possible been avoided. On some unowned parts of the lawn, and by the sides of shrubberies Wood Hyacinths may be seen in great numbers; and in similar positions Daffodils, Wood Anemones, Cowslips, and Primroses are flowering abundantly, and are much more enjoyable than when planted in large beds of formal shapes or in borders—positions in which they are too frequently met with in gardeus. In this kind of wild gardening when well carried out, as it is here, we have a succession of flowers from January to June, and that without much trouble or expense. Snowdrops and Crocuses, of course, make their appearance first; then come Daffodils, Anemones, Primroses, and hosts of other spring flowers. The vases on the terraces, being planted with Tulips and scarlet Candytuft, and edged with Nemophila, are also very attractive; when the Tulips have ceased blooming, the Candytuft takes their place, and the Nemophila, drooping gracefully over the sides of the vase, sets it off to advantage. Near a wall gay with the scarlet blossoms of the *Cydonia japonica* grow fine masses of the Common Honesty, its huge trusses of rosy blossoms waving to and fro with every breeze having a fine effect. The indoor flower department, too, is not the least attractive portion of Cliveden; the conservatory is especially gay with Camellias, Azaleas, Acacias, Schizanthuses, and other spring-flowering plants, among which we noticed a large mass of *Srelitzia Regiæ* blooming freely. On the roof are *Tacsonia exoniensis* and *T. mollissima* heavily laden with brilliant, pendent blossoms, and a Gloire de Dijon Rose, on which has been budded Maréchal Niel, is producing flowers of both varieties just now in abundance. C. S.

HYBRID TEA ROSE MRS. OPIE.—For many years after the introduction of what are commonly called Tea-scented Roses to this country from the East, the prevailing colour of their flowers was white or yellow; and if now and then pink or rose-colour were present, it was intimately blended with the yellow pigment, the result being different shades of orange or salmon-colour. Within the last few years, however, several hybrid varieties have been obtained, doubtless by means of cross-fertilization, either with some Noisette or China varieties, in which the soft shades of orange or salmon-red have been heightened into carmine or deep rosy purple, of which Duchess of Edinburgh and Chestnut Hybrid are examples. Mrs. Opie, which is a welcome addition to this class, was exhibited last season at the Crystal Palace and elsewhere, and when better known, cannot fail to be largely cultivated for forcing, as well as for cutting in the bud state for decorative purposes.—B.

EARLY-FLOWERING TOWN TREES.—Two of the most pleasing of all trees just now are the Norway and Montpellier Maples (*Acer platanoides* and *A. monspessulanum*), which form low-growing trees in St. James' and other London parks; they are especially attractive about this time of year, when every twig is terminated by dense clusters of golden-green flowers, which, unlike those of most other Maples, are developed before the leaves become fully expanded. As seen in the distance, these trees have a peculiarly warm, sunny appearance, quite different from that of any other species, and as they flourish well in smoky localities, they well deserve a place in the most select list of town trees.—B.

AMERICAN POMOLOGICAL SOCIETY'S MEETING.—The American Pomological Society, having accepted the invitation of the Maryland Horticultural Society, gives notice that the sixteenth session of this national association will be held in Baltimore, commencing Wednesday, September 12th, 1877, at 10 o'clock A. M., and continuing for three days. All horticultural, pomological, agricultural, and other kindred associations in the United States and British provinces, are invited to send delegations as large as they may deem expedient; and all persons interested in the cultivation of fruits are invited to be present, and take seats in the Convention.

Rooting Cuttings.—Cuttings of many plants can be more easily rooted if partially broken off, and allowed to hang by the bark for a couple of weeks before being planted.—"Albany Country Gentleman."

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 359.)

Heath.

Titus Andronicus. Now would I give a thousand furlongs of sea for an acre of barren ground; long Heath, brown Furze, anything.
Tempest, act i, sc. 1.

There are other passages in which the word Heath occurs in Shakespeare, but in none else is the flower referred to; the other references are to an open heath or common. And in this place no special Heath can be selected, unless by "long Heath" we suppose him to have meant the Ling (*Calluna vulgaris*). And this is most probable, for so Lyte calls it. "There is in this countrie two kinde of Heath, one which beareth the flowres amongst the stemmes, and is called long Heath." But it is supposed by some that the correct reading is "Ling, Heath," &c., and in that case Heath will be a generic word, meaning any of the British species (see Ling). Of British species there are five, and wherever they exist they are dearly prized as forming a rich element of beauty in our landscapes. They are found all over the British Islands, and they seem to be quite indifferent as to the place of their growth. They are equally beautiful in the extreme Highlands of Scotland, or on the Quantock and Exmoor Hills of the South—everywhere they clothe the hill-sides with a rich garment of purple that is wonderfully beautiful whether seen under the full influence of the brightest sunshine, or under the dark shadows of the blackest thundercloud. And the botanical geography of the Heath tribe is very remarkable; it is found over the whole of Europe, in Northern Asia, and in Northern Africa. Then the tribe takes a curious leap, being found in immense abundance, both of species and individuals, in Southern Africa, while it is entirely absent from North and South America. Not a single species has been found in the New World. A few plants of *Calluna vulgaris* have been found in Newfoundland and Massachusetts, but that is not a true Heath.

As a garden plant the Heath has been strangely neglected. Many of the species are completely hardy, and will make pretty evergreen bushes of from 2 ft. to 4 ft. high, but they are better if kept close-grown by constant clipping. The species best suited for this treatment are *E. mediterranea*, *E. arborea*, and *E. codonodes*. Of the more humble-growing species *E. vagans* (the Cornish Heath) will grow easily in most gardens, though in its native habitat it is confined to the serpentine formation; nor must we omit *E. herbacea*, which also will grow anywhere, and, if clipped yearly after flowering, will make a most beautiful border to any flower-bed; or it may be used more extensively, as it is at Doddington Park in Gloucestershire (Sir Gerald Codrington's), where there is a large space in front of the house several yards square entirely filled with *E. herbacea*. When this is in flower (and it is so for nearly two months, or sometimes more) the effect, as seen from above, is of the richest Turkey carpet, but of such a colour and harmony as no Turkey carpet ever attained.

Several of the South-European Heaths were cultivated in England in Shakespeare's time.

Hebenon.

Ghost. Upon my secure hour thy uncle stole,
With juice of cursed Hebenon in a vial,
And in the porches of my ear did pour
The leperous distilment; whose effect
Holds such an enmity with blood of man
That swift as quicksilver it courses through
The natural gates and alleys of the body,
And with a sudden vigour it doth posset
And curd, like eager droppings into milk,
The thiu and wholesome blood.

Hamlet, act i, sc. 5.

It is not easy to determine what plant is meant by Hebenon. There are two families of plants to which the name of Ebenus has been given, of which the Ebony is one, and the other is a Pea-blossomed plant of the south of Europe. Archdeacon Nares and Mr. Douce considered that the Ebony was meant, and there is no doubt that Ebony was sometimes so spelt.

A gentle youth, his dearly loved squire,
His speare of Heben-wood behind him bare.
"Faerie Queen"—*Spenser*.

and that "the juice of Ebon" is mentioned in conjunction with other deadly poisons by some of the old writers. Mr. Beisley suggests that it is a mistake for Enoron, one of the old names of the Deadly Nightshade, but I can see no reason for this suggestion. The most usual interpretation is that Henbane (*Hyoscyamus niger*) is meant. This is a native plant of undoubted poisonous qualities, though not now considered so poisonous as it was in Shakespeare's time. Gerarde says of it:—"The leaves, seed, and juyce taken inwardly causeth an unquiet sleepe like unto the sleep of drunkennesse, when continueth long and is deadly to the party." This plant, then, will satisfy the requirements of the Hebenon of Hamlet, but in the general uncertainty I am inclined to think that both Hebenon and Henbane are generic words for any strong poison. Henbane certainly was so used by the writers of that date and later, and Gerarde confuses several plants under that name, and called Tobacco the Henbane of Peru. It should be noticed that the "bane" in the name has no reference to its poisonous qualities, the original name being "Henne-belle."

Hemlock.

- (1) *Burgundy*. Her fallow leas
The Darnel, Hemlock, and rauk Fumitory
Doth root upon. *Henry V.*, act v., sc. 2.
- (2) *3rd Witch*. Root of Hemlock digged in the dark.
Macbeth, act iv., sc. 1.
- (3) *Cordelia*. Crowned with rank Fumiter and furrow weeds,
With Harlock, Hemlock, Nettles, Cuckoo-flowers.
King Lear, act iv., sc. 1.

One of the most poisonous of a suspicious family (the Umbelliferæ), "the great Hemlocke doubtlesse is not possessed of any one good facultie, as appeareth by his lothsome smell and other apparent signes," and with this evil character the Hemlock was considered to be only fit for an ingredient of witches' broth—

"I ha' been plucking (plants among)
Hemlock, Henbane, Adder's Tongue,
Nightshade, Moonwort, Leppard's-bane."

Ben Jonson.

Yet the Hemlock adds largely to the beauty of our hedges; its spotted tall stems and its finely-cut leaves make it a handsome weed, and the dead stems and dried umbels are marked features in the winter appearance of the hedges. As a poison it has an evil notoriety, as being the poison by which Socrates was put to death, though this is not quite certain. It is not, however, altogether a useless plant—"It is a valuable medicinal plant, and in autumn the ripened stem is cut into pieces to make reels for worsted thread" (Johnstone).

Hemp.

- (1) *Pistol*. And let not Hemp his windpipe suffocate.
Henry V., act iii., sc. 6.
- (2) *Chorus*. And in them behold
Upon the Hempten tackle ship boys climbing.
Henry V., act iii.
- (3) *Puck*. What Hempten homespuns have we swaggering here?
Midsummer Night's Dream, act iii., sc. 1.
- (4) *Cade*. Ye shall have a Hempten candle then, and the pap of a
batchet. *2nd Henry VI.*, act iv., sc. 7.
- (5) *Hostess*. Thou Hemp-seed.
2nd Henry IV., act ii., sc. 1.

In all these passages the reference is to rope made from Hemp, and not to the Hemp plant, and it is very probable that Shakespeare never saw the plant. It was introduced into England long before his time, and largely cultivated, but only in a few parts of England, and chiefly in the eastern counties; I do not find that it was cultivated in gardens in his time, but it is a plant well deserving a place in any garden, and it is especially suitable from its height and regular growth, for the central plant of a flower-bed. It is supposed to be a native of India, and seems capable of cultivation in almost any climate.

Herb of Grace (see Rue).

Holly.

- Song*. Heigh-ho! sing, heigh-ho! unto the green Holly:
Most friendship is feigning, most loving mere folly:
Then, heigh-ho, the Holly!
This life is most jolly.

As You Like It, act ii., sc. 7.

From this single notice of the Holly in Shakespeare, and from the slight account of it in Gerarde, we might conclude that the plant was not the favourite in the sixteenth century that it is in the nineteenth; but this would be a mistake. The Holly entered largely into the old Christmas carols.

Christmastide
Comes in like a bride,
With Holly and Ivy clad.

And it was from the earliest times used for the decoration of houses and churches at Christmas. It does not, however, derive its name from this circumstance, though it was anciently spelt "holy," or called the "holy tree," for the name comes from a very different source, and is identical with "holm," which, indeed, was its name in the time of Gerarde and Parkinson, and is still its name in some parts of England, though it has lost its other old name of Hulver. But as an ornamental tree it does not seem to have been much valued, though in the next century Evelyn is loud in the praises of this "incomparable tree," and admired it both for its beauty and its use. It is certainly the handsomest of our native evergreens, and is said to be finer in England than in any other country; and as seen growing in its wild habitats in our forests, as it may be seen in the New Forest and the Forest of Dean, it stands without a rival, equally beautiful in summer and in winter; in summer its bright glossy leaves shining out distinctly in the midst of any surrounding greenery, while in winter it is the very emblem of bright cheerfulness, with its foliage uninjured in the most severe weather, and its rich coral berries, sometimes borne in the greatest profusion, delighting us with their brilliancy and beauty. And as a garden shrub, after all the fine exotic shrubs that have been introduced into our gardens, during the present century, the Holly still holds its own. It can be grown as a single shrub, or it may be clipped, and will then form the best and the most impregnable hedge that can be grown. No other plant will compare with it as a hedge plant, if it be only properly attended to, and we can understand Evelyn's pride in his "glorious and refreshing object," a Holly hedge 160 ft. in length, 7 ft. in height, and 5 ft. in diameter, which he could show in his "poor gardens at any time of the year, glittering with its armed and varnished leaves," and "blushing with their natural corals." Nor need we be confined to plain green in such a hedge. The Holly runs into a great many varieties, with the leaves of all shapes and sizes, and blotched and variegated in different fashions and colours. All of these seem to be comparatively modern. In the time of Gerarde and Parkinson there seems to have been only the one typical species, and perhaps the Hedgehog Holly.

I may finish this notice of the Holly by quoting two most remarkable uses of the Holly mentioned by Parkinson:—"With the flowers of Holly," saith Pliny from Pythagoras, "water is made ice; and againe, a staffe of the tree throwne at any beast, although it fall short by his defect that threw it, will flye to him, as he lyeth still, by the speciall property of the tree." He may well add—"This I here relate that you may understand the fond and vain conceit of those times, which I would to God we were not in these dayes tainted withall."

Holly Thistle.

Margaret. Get you some of this distilled Cardus Benedictus, and lay it to your heart; it is the only thing for a qualm.

Hero. There those prickest her with a Thistle.

Beatrice. Benedictus! Why Benedictus? You have some moral in this Benedictus.

Margaret. Moral? No, by my troth, I have no moral meauing: I meant plain Holy Thistle.

Much Ado About Nothing, act iii., sc. 4.

The *Cardus benedictus*, or Blessed Thistle, is a handsome annual from the south of Europe, and obtained its name from its high reputation as a heal-all, being supposed even to cure the plague, which was the highest praise that could be given to a medicine in those days. Cogan, in his "Haven of

Health," 1595, says:—"This herbe may worthily be called Benedictus or Omni-morbia, that is a salve for every sore, not known to Physitians of old time, but lately revealed by the special Providence of Almighty God" (quoted by Steevens). The plant has long lost this high character.

Honeystalks (see Clover).

Honeysuckle.

- (1) *Hero*. And bid her steal into the pleached bower
Where Honeysuckle, ripened by the sun,
Forbids the sun to enter.
Much Ado About Nothing, act iii., sc. 1.
- (2) *Ursula*. So angle we for Beatrice, who even now
Is couched in the Woodbine coverture. *Ibid.*
- (3) *Titania*. Sleep thou, and I will wind thee in my arms,
So doth the Woodbine the sweet Honeysuckle
Gently entwist. The female Ivy so
Enrings the lark's fingers of the Elm.
Midsommer Night's Dream, act iv., sc. 1.
- (4) *Hostess*. O thou Honeysuckle villain.
2nd Henry IV., act ii., sc. 1.
- (5) *Oberon*. I know a bank whereon the wild Thyme blows,
Where Oxlips and the nodding Violet grows,
Quite over canopied with lish Woodbine.
Midsommer Night's Dream, act ii., sc. 2.

I have joined together here the Woodbine and the Honeysuckle, because there can be little doubt that in Shakespeare's time the two names belonged to the same plant, and that the Woodbine was (where the two names were at all discriminated, as in No. 3), applied to the plant generally, and Honeysuckle to the flower. This seems very clear by comparing together Nos. 1 and 2. In earlier writings the name was applied very loosely to almost any creeping or climbing plant. In an Anglo-Saxon vocabulary of the eleventh century it is applied to the wild Clematis (*Viticella*—Wooden-binde); while in Archbishop Elfric's Vocabulary of the tenth century it is applied to the *Hedera nigra*, which may be either the Common or the Ground Ivy (*Hedera nigra*—Wude-binde); and in the Herbarium and Leechdoms books of the twelfth century it is applied to the Capparid or Caper-plant, by which, however (as Mr. Cockayne considers), the *Convolvulus Sepium* is meant. After Shakespeare's time again the words began to be used confusedly. Milton does not seem to have been very clear in the matter. In "Paradise Lost" he makes our first parents "wind the Woodbine round this arbour" (perhaps he had Shakespeare's arbour in his mind); and in "Comus" he tells us of—

A bank
With Ivy canopied, and interwove
With flann'ing Honeysuckle.

While in "Lycidas" he tells of—

The Musk Rose and the well-attired Woodbine.

And we can scarcely suppose that he would apply two such contrary epithets as "flann'ing" and "well attired" to the same plant. And now the name, as of old, is used with great uncertainty, and I have heard it applied to many plants, and especially to the small sweet-scented Clematis.

But with the Honeysuckle there is no such difficulty. The name is an old one, and in its earliest use was no doubt indifferently applied to many sweet-scented flowers (the Primrose amongst them); but it was soon attached exclusively to our own sweet Honeysuckle of the woods and hedges. We have two native species (*Lonicera Perelymenum* and *L. Xylostenm*), and there are about eighty exotic species, but none of them sweeter or prettier than our own, which, besides its fragrant flowers, has pretty, fleshy, red fruit.

The Honeysuckle has ever been the emblem of firm and fast affection—as it climbs round any tree or bush that is near it, not only clinging to it faster than Ivy, but keeping its hold so tight as to leave its mark in deep furrows on the tree that has supported it. The old writers are fond of alluding to this. Bullein in "The Book of Simples," 1562, says very prettily, "Oh, how swete and pleasant is Woodbinde, in woodes or arbours, after a tender, soft rain; and how friendly doe this herbe, if I maie so name it, embrace the bodies, armes, and branches of trees, with his long winding stalkes, and tender

leaves, openyng or spreading forth the his swete Lillis, like ladie's fingers, emog the thornes or bushes" (quoted by Johnstone); and Chaucer gives the crown of Woodbine to those who were constant in love:—

And tho that weare chaplets on their hede
Of fresh Woodbinde, be such as never were
To love untrue in word, thought ne dede,
But aye stedfast; ne for pleasaunce ne fere,
Though that they should their hertes al to-tere,
Would never flit, but ever were stedfast
Till that their lives there asunder brast.

The Flower and the Leaf.

The two last lines well describe the fast union between the Honeysuckle and its mated tree.

Hyssop.

Lago. 'Tis in ourselves that we are thus or thus. Our bodies are our gardens; to the which our wills are gardeners; so that if we will plant Nettles or sow Lettuce; set Hyssop, and weed up Thyme; supply it with one gender of herbs or distract it with many, either to have it sterill with idleness, or maimed with industry; why the power and corrigible authority of this lies in our wills.

Othello, act i., sc. 3.

We should scarcely expect such a lesson of wisdom drawn from the simple herb-garden in the mouth of the greatest knave and villain in the whole range of Shakespeare's writings. It was the preaching of a deep hypocrite, and while we hate the preacher we thank him for his lesson.

The Hyssop (*Hyssopus officinalis*) is not a British plant, but it was held in high esteem in Shakespeare's time. Spenser spoke of it as—

Sharp Isope good for green wounds remedies—

and Gerard grew in his garden five or six different species or varieties. He does not tell us where his plants came from, and perhaps he did not know. It comes chiefly from Austria and Siberia; yet Greene in his "Philomela," 1615, speaks of "the Hyssop growing in America, that is liked of straungers for the smell, and hated of the inhabitants for the operation, being as prejudicial to the one as delightful to the other." It is now very little cultivated, for it is not a plant of much beauty, and its medicinal properties are not much esteemed; yet it is a plant that must always have an interest to readers of the Bible; for there it comes before us as the plant of purification, as the plant of which the study was not beneath the wisdom of Solomon, and especially as the plant that added to the cruelties of the Crucifixion. Whether the Hyssop of Scripture is the *Hyssopus officinalis* is still a question, but at the present time the most modern research has decided that it is.

Insane Root.

Macbeth. Were such things here as we do speak about?
Or have we eaten of the Insane Root
That takes the reason prisoner?

Macbeth, act i., sc. 1.

It is very possible that Shakespeare had no particular plant in view, but simply referred to any of the many narcotic plants which, when given in excess, would "take the reason prisoner." The critics have suggested many plants—the Hemlock, the Henbane, the Belladonna, the Mandrake, &c., each one strengthening their opinion from coeval writers. In this uncertainty I should incline to the Hemlock from the passage in Green's "Never too Late," 1616 (quoted by Steevens)—"You gazed against the sun and so blemished your sight, or else you have eaten of the roots of Hemlock, that makes men's eyes conceit unseen objects."

H. N. ELLACOMBE.

(To be continued).

Well-fed Apple Trees.—The quality of food from a well-fed Apple tree is altogether superior to that of a half-starved tree of the same variety. Few farmers think it profitable to bring poorly-fed beef to market, and there ought to be very few who would think it profitable to raise poorly-fed Apples. Let us have fat Apples as well as fat beef. Feed the Apple trees. Too-dress with well-decayed stable manure, and apply superphosphates, bone-dust, and potash salts.—*Lewiston Journal*.

Mr. Cramb, for many years gardener to Earl Ducie, at Tortworth Court, Wootton-under-Edge, Gloucestershire, died suddenly, on the 27th ult., from heart disease. He was sixty-eight years of age.

THE FLOWER GARDEN.

REYNOLDS HOLE ROSE.

WELCOME Reynolds Hole Rose to its high place of honour in THE GARDEN! It was a happy thought of the artist to place the Roses François Michelin and Reynolds Hole on the same plate; not that one fears that either the man or the Rose bearing his honoured name is not strong enough to stand alone, but the brilliancy of the Rose in question is marvellously developed when contrasted with the soft pink of its lovely companion. Directly I saw the plate the thought struck me that the Pink Rose should have been Mrs. Reynolds Hole. Not till the author of the "Book about Roses" is thus companioned, if I may use the term, by Rosarians, will the first instalment of the debt due to him for popularizing Rose growing and showing be paid. Unfortunately, hitherto, Reynolds Hole has not reached its best here, and had I not seen it in full magnificence at Mr. Cant's and other places last year, I should have thought the artist had thrown a dash of the ardour of his imagination into the brilliancy of the Rose—but it is really not so; it is by no means flattered, and I hope to equal the plate with my Reynolds Hole Roses this season. All Roses need humouring, and require a great amount of

patience in their cultivation for a year or two. It seems often to take them some years to get over the weakening strain of excessive propagation, and to become accustomed, as it were, to their new situations. I wish the Rev. Reynolds Hole would write an article on the "humouring" of Roses in private gardens. Can it be that they are conscious at times of their own merit, that, like their growers, they need "the cooper"? Or may not the uncertainty of their full development be termed the "whims of the Roses," to give their masters a lesson in patience, a virtue that few Roses fail to crown with a rich reward in the end? I may add that notwithstanding the cold weather the Roses which were not pruned till the middle of April look remarkably well, and are breaking

strongly. Many buds were showing on the extremities of the shoots and a standard of Maréchal Niel had over fifty buds ready to open. These were all cut off, and the plant is now breaking strongly again. Maréchal Niel on walls in the open air looks starved and miserable. Indoors it has been very fine, only paler far than outside; that, I consider, adds to its beauty; it is an exquisite, soft primrose, something like the old and now seldom seen Smith's Yellow, but with double the number of petals and ten times the fulness of fragrance. I should almost be inclined to rank the Maréchal Niel Rose under glass as second in sweetness to what I consider the premier Rose for exquisiteness of odour—Devoniensis.

D. T. FISH.

BRIDGES IN GARDENS.

OUR OWN opinion is that no bridge should ever be made in a garden where it can possibly be avoided. But everybody knows that puerile pretexts are sought for to justify the making of bridges where they are never wanted. If we lived in a sahara where a real bridge was unseen there would be more excuse than at present for bridge puerilities. However, there are cases where they are really needed in gardens, and this being so their construction in a not too intrusive manner, and their embellishment or even partial concealment where

required are of some importance to those interested in garden design. For this reason we give an illustration of a picturesque bridge connecting two islands in a large artificial lake. Here the appropriate planting of the banks and the picturesque drapery of the bridge are noticeable. We are bound to add, however, that it is one of the positions where a bridge was unnecessary, except for the pleasure of making one.

CULTURE OF NEAPOLITAN VIOLETS.

FOR small bouquets this Violet is unsurpassed by any other variety, and, although it may be had in flower all through the winter and spring, yet near London market gardeners even do not pay much attention to it, although they grow other kinds by the acre. Single crown runners of it may now be obtained from old plants in abundance; they should be cut off, and pricked out 1 ft. apart into a half-shady border, in good rich soil, keeping them well watered during dry weather, and the ground between the rows clear of weeds by means of the frequent use of the hoe. Towards the middle of the summer

a little manure-water may be given them with advantage, but it would be better still to mulch with thoroughly decayed stable manure, free from worms. All young runners should be kept picked off as fast as they appear, and in the middle of September, after being well watered, the plants should be lifted with as good balls as possible, and either potted or planted out in a frame previously prepared for them, allowing a space of 3 in. or 4 in. between each plant. The pit or frame should have been filled with fresh stable-manure, or, if at hand, Oak leaves are best, inasmuch as they retain a steady temperature for a longer period than other fermenting material. A foot thick

of sandy loam and leaf-soil should be placed on the bed in which to set the plants, and after planting a good watering may be given and the lights closed and shaded for a few days until root-action has again commenced, after which abundance of air must be given night and day on every favourable opportunity. Little or no water will be necessary, but if the soil get very dry, the lights should be taken off early in the morning of some fine day, and the water applied in sufficient quantity to soak the whole of the soil, and the plants should be left exposed to sun and air until the foliage has become thoroughly dry. The plants in pots should occupy a similar position to those planted out until they show bloom, when, if they be moved to a light, airy shelf near the glass in a cool house, their flowers will open freely. Damp is the greatest enemy which the Neapolitan Violet has when in flower, therefore it is obvious that whilst the roots should be abundantly supplied with water, the foliage should be afforded as much air as possible to insure its being kept perfectly dry. Red spider often attacks the leaves of Violets during the summer when planted out, and for this there is no remedy equal to that of planting in rich soil in order to keep the plants growing vigorously. When coming into bloom, weak manure-water, in which has been put a little soot, may

Bridge connecting Two Islands.

be advantageously applied at every alternate watering. If the flowers, when picked, be required to travel any great distance, it is best to place them loosely in a small box lined with Ivy leaves, for if tied in bunches, as they often are, they do not last in good condition nearly so long as when placed loosely in the box. C. S.

Yellow Gladiolus (*G. angustus*).—My bulbs of this lovely and early flowering plant came to me direct from the Cape, and therefore in my anxiety to preserve them for some years I kept them in the greenhouse, but they were never satisfactory, being attacked with red spider and green fly: I then tried them in a box frame, but they grew too tall, and their foliage and blooms were damaged, and besides they evidently did not like the confinement of pots. Last summer I turned them all out into the border, and now I have some dozens of spikes of their lovely primrose-coloured blooms, and if cut before expansion, their buds gradually open in water, or better still in wet sand. Another thing, last Friday morning when I went down my garden, all the Tulips, Fritillarias, Scillas, and others were prostrate, but this Gladiolus was unscathed and as upright as ever. If I remember correctly, I once saw the same plant in a stand of hardy flowers at the Crystal Palace from Messrs. Ware's under the name of *G. flavus*. There are two other plants which I do not often see, but which are well worth growing, viz., *Scilla campanulata alba* and *S. nutans alba*.—JOHN E. DANIEL, *Terrace, Epsom*.

Choice Hardy Plants.—A few plants just now in bloom deserve notice because they are rarely met with in gardens. Among them may be mentioned *Viola montana*, the gem of this large and varied family. It is lovely either in pots or pans, and as it is of a comparatively meagre habit it must not be overpotted; a plant of it with two crowns now in flower in a 5-in. pot has a considerable number of its pretty mauve blooms expanded; these issue from the centre of a mass of small, finely-cut leaves, the shape of which gives to the plant the common designation of the Bird's-claw Violet. Half-a-dozen such plants in a 10-in. pan neatly mossed could not fail to elicit the admiration of everybody. *Myosotis rpicola* is another of these Alpine gems that fairly enchant those who are fond of hardy plants. It is herbaceous, that is, it loses its foliage in winter, and sends up renewed growth in the spring; under glass it begins to flower in the middle of May; the blooms, which are small and of a rich blue, are borne in short sprays. Altogether when in full flower this plant does not exceed 6 in. in height; a pan of it is well worth attention. In *Veronica repens* we have an exceedingly close-growing rock plant, that opens its pretty little flowers about the beginning of May. It is, if possible, dwarfer in habit than the dwarfest of *Sedums*, and, as it spreads, covers the soil with a dense growth; the flowers resemble those of the *Nemophila* in shape, but are much smaller, and pure white speckled with lavender. This, if grown in a cool house, should be in a pan, but it is so hardy that it is well suited for outdoor rockwork. *Iberis jucuuda* is probably the most fragile of all the family to which it belongs; although it is quite hardy, it seems best suited for pot culture, as its growth is small and the foliage minute; the flowers are of a deep rosy-pink, an unusual tint among *Iberises*. A pretty companion for these small plants is found in the Butterwort, of which there are several varieties, but perhaps the large-flowered Irish kind is the best. This is also a good plant for a pan, and if kept in a moist and shaded place it will thrive remarkably well, and produce an abundance of blooms. It propagates itself freely by means of side crowns, and these, if carefully pricked out in the autumn, soon grow into blooming plants, and succeed best in a cool house or frame.—A. D.

Romneya Coulteri.—This singular Californian Poppywort is found on the borders of streams near San Diego, and is a strong-growing, much-branching plant, with lobed, glaucous foliage. The flowers are large, nearly equalling in size those of the White Water Lily; the colour is pure white, the stamens very numerous, and the anthers golden yellow. This Poppy must be a showy plant in its own country, as it is apparently very floriferous; but it is doubtful if it will be so valuable here, where the summer-heat is not sufficiently powerful for perfecting its growth and fully developing its flowers before our early autumn frosts overtake it. A plant of it which bloomed in the open border at Glasnevin, in October, 1876, was about 4 ft. high, and 3 ft. through, with numerous lateral shoots, each of which, as well as the terminal branches, bore a flower-bud at the point: Dr. Moore received it in March of that year, and it was then, I believe, a mere cutting. Mr. Thompson, of Ipswich, with whom it bloomed in September last, thus describes the cultural treatment which his plants of it received:—"They were raised from seed during the summer, and were kept in a cool house in winter, though they are capable of resisting a few degrees of frost in dry soil.

Under glass the plant is almost, if not quite, an evergreen, and when turned out in the open border in May, the stems soon reached a height of 2½ ft. to 3 ft., producing a single flower at the summit of each, which developed somewhat slowly, and expanded about the middle of July. The petals, six in number, arranged in two series, are of the purest white, broadly fan-like in form and slightly fragrant, the flowers being quite 4 in. across, and continuing expanded throughout the day. Notwithstanding the heat of the weather, they remained open from three to four days, proving that they are somewhat less fugacious than many plants of the same Order. This *Romneya* is a true perennial, and may doubtless be easily preserved from year to year in a cold frame. I do not think it can be successfully treated as a perfectly hardy perennial." This plant was first described, and the genus founded, by the late Dr. Harvey, of Dublin.—B.

Effects of the Frost on Lilies and other Border Plants.—Some of your readers may like to compare notes as to the damage done by the late severe frosts to Lilies growing out-of-doors. The meteorological authority of our district has given me the exact temperatures as follows:—On May 3, the thermometer at 4 ft. from the ground, fully exposed, descended to 25°, and a radiation thermometer on the grass to 21·75; on the 4th, the corresponding readings were 23·5 and 19·75. In the open border unprotected *L. californicum*, *Humboldti*, *Martagon*, *dalmaticum*, *Szovitsianum*, *Browni*, *pyrenaicum*, *chalconicum*, *tigrinum*, and *umbellatum* appear to be unharmed; out of very many *L. auratum*, a few seem a little touched, but though I longed for the white parsons with which my friend and neighbour Mr. McIntosh shelters his favourites, the great majority seem to be all right; some of them are from 2 ft. to 3 ft. high: I measured one stem 2½ in. in circumference at the base; the outside leaves of *L. giganteum* are cut badly, but in the case of one, measuring 1 ft. 10 in. in height, and 6½ in. in circumference at the base of the stem, though the side leaves are cut, the stem and inner leaves appear to be untouched. Among border plants in bloom I noticed *Anemone cortusoides amœna* a good deal cut, while *A. palmata* and *A. Pulsatilla* are untouched; the more forward buds of *Azalea mollis* and *Dicentra spectabilis* are cut; *Colchicum speciosum* in bud and *Alpine Auriculas* are unharmed; *Trilliums* in the shade are likewise uninjured; *Astilbe japonica* is considerably hurt; a large clump of *Cypripedium spectabile* had some shoots browned; *Adonis vernalis*, with its glorious yellow flower, is in full beauty; on the raft *Lobelia cardinalis* and *Cypripedium spectabile* are apparently untouched.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

Primula cortusoides amœna alba.—I find this *Primula* to be one of the easiest to cultivate; it succeeds well with me under the same conditions as *P. c. amœna*. I grow both in pots, large or small according to the size of the plants, in a mixture consisting of two-thirds rich loam and equal quantities of well-rotted manure and leaf mould, adding a small portion of sand. I pot them immediately after they have flowered and place them on a bed of ashes, giving plenty of water. They are greatly assisted by being fed during their growing and flowering seasons with a little weak liquid manure. I winter them in a cold frame, giving them abundance of air except during severe frost, and under this treatment I get both good foliage and flowers. I should say that Mr. Harris's variety (see p. 329) is not the true *P. c. amœna alba*, but *P. c. amœna alba viridis striata*, a kind which has a very small flower, and is scarcely worth growing. The true kind has flowers equal in size and strength to those of *P. c. amœna*; they are pure white, and when produced by established, well-grown plants, equally abundant. I should recommend Mr. Harris to grow the true variety, which is known in the trade as *P. cortusoides amœna grandiflora alba*, a very charming plant; *P. c. lilacina* and *hybrida* are also varieties well worth growing.—E. JENKINS, *Sydenham Hill*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Viola Sir Walter Scott.—I saw this new *Viola* shortly after it had been raised and just when it was coming into blossom, and I have never seen a more effective purple flower of any kind for bedding purposes than it is. Each blossom is about the size of a five shilling piece, and so crowded that hardly any of the foliage can be seen.—A. NORRIS, *Glasnevin*.

Erica mediterranea.—We have several bushes of this hardy, spring-blooming Heath now in full bloom, and it well deserves more attention than it receives on account of its quick growth and ornamental character when in blossom. It will succeed in the most exposed situations, and with us it has attained a height and width of 6 ft. The flowers, which are bright lilac, are about as sweetly-scented as those of a Hawthorn.—J. M.

Sedum acre elegans for Border Edgings.—This is the best plant that can possibly be used as an edging for shrubbery borders, or such as are occupied by hardy herbaceous plants. Even in situations where Grass will not grow this *Sedum* will succeed, and in addition to its having a light and lively appearance, a band of it some 6 in. in width when well established will prevent the soil from the borders being washed into the walks almost as effectually as tiles, and certainly better than Box.—C. S.

MESSRS. HAYES' GARDEN AT EDMONTON.

In places where plants and fruits are wholly grown for market, the rule is to make them produce as much as possible without much attention being paid to appearances: for in many cases clean walks, neat hedges, and other items calculated to add to the attractiveness and enjoyment of the place, are only secondary considerations, and often thought unprofitable. There are, however, a few establishments near London that form an exception to this rule, and perhaps a better example of what a market garden should be could not be found than that of Messrs. Hayes, of Edmonton. Here are many acres of land devoted to the culture of hardy fruit, flower, and vegetable crops, all of which appear to thrive in the most satisfactory manner. The indoor department, however, forms the most important feature, and to it is devoted much care and attention. The glass structures consist of about thirty houses of medium dimensions—from 40 ft. to 50 ft. long, and 15 ft. to 20 ft. wide—mostly span-roofed, as well as a large number of span and lean-to pits. Flowering plants suitable for market purposes occupy the whole of the glass structures, no fruit being grown indoors, except a few Vines, which have been planted for a number of years, and which are here and there to be found in the oldest of the houses. These are, however, allowed to remain more for convenience than for profit, but they serve to illustrate the value of the extension

A Tea Rose House at Edmonton.

system. Tea and Fairy Roses occupy a prominent position in this place, and Hybrid Perpetual Roses are also grown to some extent. The Tea Roses are chiefly planted out, the plants themselves being trained in lines under the roof in such a manner as to obstruct as little light as possible from other kinds of plants which are grown underneath them. One span-roofed house, however, is entirely devoted to Tea Roses. The plants are mostly grown in large pots and trained up a series of wooden trellises, about 6 ft. or 8 ft. in height and from 3 ft. to 4 ft. apart, as represented in the annexed engraving. A path runs along one side of the house, so that the blooms are easily gathered. By this means the whole of the space is utilized most profitably, and the plants receive abundance of light and sunshine on all sides. A few fine examples of *Maréchal Niel* and *Gloire de Dijon* may also be seen here planted out in some of the houses, the branches being trained as before stated in lines along the roof. Several plants thus circumstanced, and which had been planted only two years, had made over 35 ft. of growth each, some of the shoots being as thick as a good-sized walking-stick, and bearing hundreds of blooms. Of Fairy Roses, about 10,000 are grown yearly; the plants are struck from small pieces of the young tops inserted in sandy soil in May and June, and by the following spring they form little bushes loaded with buds and rosy-coloured blossoms. Such plants as these find a ready sale in the markets, numbers of them being cut up and used in bouquet-making. During the time in which the plants are coming into bloom, they are arranged on stair-like stages,

receive abundance of air and water, and are frequently fumigated to keep down insects. They are grown in 6-in. pots; many thousands of them can therefore be placed in a medium-sized house, and when in bloom they have an interesting appearance. Heliotropes are grown here expressly for furnishing cut blooms. The plants were formerly in large pots, but when it became necessary to give them more pot room, they were so large that the operation became a difficult one. The pots which they occupied were therefore broken up, and the balls containing the roots were covered round with soil; therefore they are practically planted out. In this position they have been for about twenty-five years, and they now form a dense bank from 8 ft. to 10 ft. high and from 9 ft. to 10 ft. wide, and from 40 ft. to 50 ft. in length. From these plants abundance of blooms can be cut at all seasons, and during the winter months they are especially valuable, all the attention required being a little water during very dry weather, and removing decayed leaves. The blooms are cut in large quantities, several times a week, all the year round. Another house is filled with Maiden-hair Fern, grown in large pots, to furnish a supply of fronds in a cut state. Pelargoniums are well grown in this establishment, both for sale in the shape of plants and for furnishing cut bloom, for which Gauntlet is the principal kind grown. A dark variety named Bonnie Charlie is also used for the same purpose. Its habit of growth is not particularly good, but its flowers are of a rich dark velvety-crimson, and old plants, when kept liberally supplied with water, grow and flower freely the whole year round. Beauty of Edmonton is also an excellent kind, the flowers having a fringed edge similar to those of the well-known Dr. Andry; they are brilliant crimson in colour, and are more conspicuous than those of any other variety with which I am acquainted. Pelargoniums for sale in pots are grown without any fire-heat whatever, except during very severe weather. Abundance of light, air, and water is given them, but they receive little in the way of stimulating manures. The foliage, nevertheless, is large and beautifully green, and almost completely conceals the pots, and the flowers being produced without forcing last for a much longer time than those produced on plants that have been subjected to fire-heat and stimulating manures.

Fuchsias are extensively grown, the principal batch coming into flower early in April, when they are most valuable in the market. The plants are struck in autumn for spring blooming, and in spring for the summer and autumn supply. The cuttings are inserted thickly in 6-in. pots, and when well rooted are shifted singly into 3-in. pots. When again established, the shoots are cut back so as to induce the plants to grow bushy, and when the pots which they occupy are filled with roots they receive their final shift into 5-in. or 6-in. ones. Each plant is supported by a central stake, to which the branches, when in bloom, are tied in such a manner as to form a perfect but by no means a formal pyramid. Mrs. Marshall is the chief light-coloured kind grown, the dark-coloured varieties being *Arabella*, *Wave of Life*, *Catherine Hayes*, and several other good free-blooming sorts. Gardenias for cut blooms are grown in 10-in. and 12-in. pots. They are allowed to grow from 3 ft. to 4 ft. high and from 2 ft. to 3 ft. through at the base, and in April, when I saw them, they were loaded with buds and blossoms. Mr. Hayes prefers growing them in pots, on account of their being more easily cleared of insects than when planted out permanently, and, moreover, they can be moved from place to place whenever it happens to be necessary to do so. Hydrangeas are also extensively grown here; they consist chiefly of bushy plants with several shoots, each of which bears a large head of pink blossoms. They are struck from cuttings put in in spring, and are grown on in frames during summer, and when in bloom a large lean-to house with a narrow path along the front and a stage at the back is entirely devoted to them. The stage is erected in the form of stair-like shelves within 2 ft. of the glass, on which the plants are arranged, and to see the hundreds of large heads—some of which measure from 15 in. to 18 in. in diameter—is, indeed, an attractive sight. In another nursery, also belonging to Messrs. Hayes, there are five or six span-roofed houses of very large dimensions, viz., from 120 ft. to 130 ft. long and about 20 ft. wide. All round the sides of these houses

a stage is erected, and large specimens occupy the centre. Here are grown enormous large of Cinerarias, Primulas, Scarlet Pelargoniums, Heaths, Solanums, &c. The Cinerarias are raised from seed sown in the spring, and the young plants are potted on in good, rich loam during the summer, until they occupy 6-in. pots. In autumn they are placed in the houses, and when they come into bloom the best are selected and moved to a low, span-roofed pit for seeding purposes, and the rest are taken to market. Those intended for seed are placed in sections according to their colours, and every possible precaution is taken to prevent cross-fertilization. Abundance of air is admitted whilst the plants are seeding, and they are kept supplied with water at the roots. As fast as the seed ripens it is gathered, and should any fall to the ground (which is covered with ashes), they quickly germinate and furnish a supply of plants for next season's blooming. Primulas, both white and rose-coloured, are grown wholly for the seed which they produce. The plants are raised from seed sown in summer, potted on into 6-in. pots, and arranged on large stages in lean-to houses, the white and rose-coloured kinds being kept in houses at a distance apart from each other. Great attention is paid to watering and ventilating after the plants have formed their seed-pods as well as before, and during very hot sunshine a little shade is afforded them. Solanums are struck from cuttings put in in spring, potted into 3-in. pots, and finally shifted into 6-in. ones, in which they are allowed to fruit. They are subjected to a temperature of from 50° to 60°, have their shoots stopped several times during the spring and summer, receive abundance of air when in bloom, and in autumn and winter they form bushy plants, loaded with bright orange-scarlet berries. Scarlet Pelargoniums are grown extensively, four houses of the above-named dimensions being occupied by them in the spring. They are propagated from cuttings inserted in the autumn, grown on in good sandy loam, and potted into 6-in. pots; the bloom which they produce during winter is cut for market, and in April and May, when the plants are in full flower, they find a ready sale for furnishing vases and for planting out in cases in which immediate effect is desired. The shoots are stopped during the growing season, and when in full bloom in the spring they receive liberal supplies of weak manure-water. Plants for furnishing vases and window-sills are obtained from cuttings inserted in the spring; they have their shoots kept well pinched in, and in the following spring fine plants from 12 in. to 15 in. high, and as much through, loaded with fine spikes of bloom, is the result. The variety grown is Vesuvius, which is dwarf in habit and a good winter-blooming kind.

C. W. S.

The Fruits of Central Asia.—Gardens constitute the beauty of all this land. The long rows of Poplar and Elm trees, the Vineyards, the dark foliage of the Pomegranate over the walls, transport one at once to the plains of Lombardy, or of Southern France. In the early spring the outskirts of the city, and indeed, the whole valley, are one mass of white and pink with the bloom of Almond and Peach, of Cherry and Apple, of Apricot and Plum, which perfume the air for miles around. These gardens are the favourite dwelling-places in summer, and well they may be; nowhere are fruits more abundant, and of some varieties it can be said that nowhere are they better. The Apricots and Nectarines I think it would be impossible to surpass anywhere. These ripen in June, and from that time until winter, fruit and Melons are never lacking. Peaches, though smaller in size, are better in flavour than the best in England; but they are far surpassed by those of Delaware. The big blue Plums of Bokhara are celebrated through the whole of Asia. The Cherries are mostly small and sour. The best Apples come either from Khiva or from Susak, to the north of Turkistan; but the small white Pears of Tashkent are excellent in their way. The Quince, as with us, is cultivated only for jams or marmalades, or for flavonriog soup. Besides Water Melons, there are in common cultivation ten varieties of early Melons and six varieties which ripen later, any of which would be a good addition to our gardens. In that hot climate they are considered particularly wholesome, and form one of the principal articles of food during summer. When a man is warm and thirsty, he thinks nothing of setting down and finishing a couple of them. An acre of land, if properly prepared, would produce in ordinary years from 2000 to 3000, and in very good years twice as many. Of Grapes I noticed thirteen varieties, and most of them remarkably good.—“Turkestan,” by EUGENE SCHUYLER.

WALL GARDENING.

This is a subject which deserves more attention than it has hitherto received. The annexed engraving represents a pendent, floriferous mass of *Aubrietia purpurea*, which may now be seen hanging down the face of a sunny brick wall in High Street, Upper Tooting, a position in which it has been a noticeable object in spring for these last ten or twelve years. This little bit of wall gardening is purely accidental; but when new garden walls are being constructed, how easy it would be to leave little recesses here and there into which soil, seeds, and suitable plants might be introduced. In some cases

Aubrietia purpurea growing on a wall.

even turf walls might be especially constructed for choice, little herbaceous plants and bulbs, many of which would grow much better thereon than when planted in ordinary borders. In many country gardens the crumbling old walls are always attractively clothed with common succulents and hardy flowers such as Wallflowers, Snapdragons, Arabis, or Aubrietias. The last-named plant is admirably suited for draping dry walls; to establish it we need only sow the seed in any mossy or earthy chinks in autumn or spring.—B.

Corn Salad.—This forms an excellent and nutritious salad, little known and little cultivated. Great quantities of it are grown in France and consumed during the winter months. The little daisy-like tufts are cut off near the ground, thrown into water, washed clean, and switched dry in a towel; then they are put in a salad-bowl, with a bit of Tarragon and Chervil chopped up fine. The plant is not cut up, but left entire. Oil and vinegar, pepper and salt, are added of course, and the result is a very excellent dish. Seed of this plant is sown at the end of August. Choose on a wet day a small piece of dug ground, and with the spade smooth the surface over equally. Sow the seed on the surface, and if the weather be likely to be dry, shade with a mat laid on flat, a stick or two being laid across the bed beneath. In a week or so, the little plants will appear in thousands, when the mat may be removed. They are ready for use after the first frost, and are better for frost, which makes them tender and crisp.—“Florist.”

Kew Gardens.—If any man's heart be sore and his eyes heavy, let him forthwith take horse or rail to Kew and live an afternoon in the garden there. If that cure him not, nothing will. Azaleas are in all their glory, and Camellias are bursting from their buds. A walk through No. 4 house is a kind of mild intoxication unattended by headache; the air is full of a hundred delicate scents, and I can testify to an instantaneous cure of heavy eyes effected by one plant of *Erica Cavendishiana* in this house. A lady, on her first visit to England, was walking in Kew Gardens the other day; she was, on the whole, much pleased, but was greatly shocked at the notice which she read at every turn, that “birds'-nesting is strictly forbidden.” “How you are severe and cruel in this country,” she at last sorrowfully exclaimed, “that even the little birds may not make their nests in your public gardens.”—“Vanity Fair.”

CYCLAMEN-FLOWERED NARCISSI.

Those kinds of Narcissi that are distinguished by their graceful habit and reflexed petals are so delicately beautiful, and at the same time so distinct from their congeners, that it is a matter to be regretted that they are so rarely met with in even our best collections of hardy plants. The reflexed Narcissi are represented by *N. calathinus* and *N. triandrus*, and of both there are more or less distinct forms, but all readily referrible to one or other of these types. We recently gave a description of *N. calathinus* in THE GARDEN (see p. 262) from fresh specimens kindly sent to us from the Naval Hospital Gardens, at Brest, by M. Blanchard. We now furnish an engraving of two forms of *N. triandrus* contrasted with the creamy-white or French form of *N. calathinus*, from which it will be seen that size of flower and length of the cup or corona afford the main points of distinction between them. Fig. 1 in our illustration represents a two-flowered scape of *N. triandrus pulchellus*, which is by far the most common form of this species as seen in gardens; it has yellow petals, and a creamy-white rounded cup. When well-grown this is a lovely plant, and a large bed of it is now most profusely in bloom in Mr. R. Parker's nursery at Tooting, some of the scapes bearing from six to eight finely developed flowers. Fig. 2 represents the creamy-white form of *N. calathinus*, which is by far the largest and most distinct plant in the group to which it belongs, and never appears to have been successfully grown in English gardens. Fig. 3 is a solitary-flowered Portuguese form of *N. triandrus*, but in its elongated cup and creamy-white colour it more nearly approaches *N. calathinus* than does any other form of *N. triandrus* which I have yet seen, and it agrees with the last-named in being less vigorous in our northern climate. As a garden plant *N. triandrus pulchellus* is the finest in this group, but *N. calathinus* and the other forms of *N. triandrus* are so delicately beautiful as to be well worthy of careful pot culture. In many warm sheltered parts of England, however, especially near the southern coast, plants of *N. calathinus* possibly might be grown successfully in raised, well-drained beds of light, rich, sandy soil in the open air. In the Garden of Plants in Paris I have recently seen this delicate species flowering most abundantly in 5-in. pots filled with light sandy compost. B.

THE FRUIT GARDEN.

BLISTERED PEACH AND NECTARINE LEAVES.

OWING to the cold, unpropitious weather that has prevailed for a long time past, and more particularly during the latter part of April and early in the present month, Peach and

Nectarine leaves have suffered a severe check, the effect of which is now showing itself in the crippled state of many of the trees. Instead of the leaves unfolding and the shoots elongating, as they should, the points thicken and swell into warty-looking excrescences that have a singular appearance. Many of the leaves also are blistered to a serious extent, and instead of warm weather rectifying matters, it appears to bring on a more rapid enlargement of the damaged parts. As most districts have been visited by cold cutting winds, and few trees have escaped injury, many Peach growers may be in a dilemma as to what course to pursue to get them right again. The best thing is to examine them at once and pick off every deformed leaf. Such excrescences and malformations of leaves appear to have almost as debilitating an effect on the Peach as tumours have on the bodies of animals, as both are fed and kept growing at the expense of the animal or tree afflicted with them. No half measures, therefore, are of any avail, and it is useless expecting a healthy, satisfactory growth so long as these blistered leaves remain on, diverting the course of the sap and taking the greater proportion of it to themselves, as is shown by the rapid manner they enlarge, and how little progress the young shoots make while the tree has them to support. It is generally supposed that frosts are the cause of Peaches and Nectar-

Cyclamen-flowered Narcissi.

ines getting into their present unsatisfactory condition, and no doubt they have much to do with it; but that cannot have been the case this season, as they were not forward enough when frost occurred of sufficient severity to reach anything sheltered against the face of a warm wall. Sudden transitions from heat to cold are just as likely to produce it, as the tender tissues are unable to endure such rapid changes as those to which the leaves have been subjected through sudden peeps of sunshine alternately with cold winds raising or depressing the temperature against a wall as

much as 30° or 40° in the space of a few minutes. It is, therefore, not surprising that such delicate leaves as those of the Peach and Nectarine have suffered in the way they have, or that green fly should be more than usually troublesome, a fact to be attributed to the slow growth the trees have made this season, of which these pests are sure to take advantage. If it be desired to save the lives of the trees and to have a crop of fruit next year, no pains must be spared to keep them clean and healthy now, as so much depends on the kind of growth they make during the next month or so, for, should this not be clean and healthy, it is impossible for the fruit-buds to become fully developed or the young wood to attain that degree of solidity and ripeness to carry it safely through the winter and lead to successful results.

It is therefore highly important that they should be kept clear from aphides, and to rid them of these there is nothing so safe and effectual as Tobacco-water; and the best way of obtaining this is to soak some common Tobacco in boiling water and then strain it through a fine sieve or coarse cloth that it may readily pass through the tube of a syringe. Insecticides containing much alkali, as most of them do, may be very well for certain purposes, but highly dangerous if applied to Peaches and Nectarines at this early fruiting stage, as they damage the tender skin, especially of the former, the downy covering of which gets so coated over as to stop their swelling. If used at all on the above, it should be only at the rate of an ounce or so to a gallon of Tobacco water, the latter of which may then be weaker than would be effectual were the Gisburst or some other kind of insecticide not added. With any of these used in the before-named proportion, 1 lb. of common strong Tobacco will be sufficient to make 12 gallons, which, if applied at a temperature of 80° or 90°, will be much more effectual than when used cold, as the heat adds greatly to its penetrating powers on the skins of the insects, which soon succumb under its influence. The evening of a warm day is the best time for applying it, as then there is no risk of injury from the sun, and it can be allowed to remain on all night to take effect, when the following morning a good washing from a garden engine will dislodge the survivors, and wash off excreta or other deposit the flies or mixture may have left. Indeed, where it can possibly be done, the trees should be syringed once daily whenever the weather is warm and dry from this time till the fruit is ripe and again after, by which means the leaves may be kept perfectly healthy and free from red spider, provided the trees are not allowed to suffer from want of water while carrying a crop. To prevent this, it is advisable at this time to give a good mulching of half-decomposed manure now that there is plenty of moisture in the soil, and thus intercept its escape by evaporation, which process, now that the sun begins to be powerful, goes on at a rapid rate. It should be borne in mind that trees planted against high walls having a southern aspect are not at any time so well circumstanced as regards rainfall as others in less sheltered positions, and with sharp sloping borders firmly trodden, much of the wet that falls during the autumn and winter runs off the surface before it can penetrate. This and the practice of cropping borders are frequent causes of Peach and Nectarine trees being in the unsatisfactory state we frequently see them, for if they lack moisture at the roots at any time they are sure to get out of health. Bud-dropping, red spider, and mildew are the evils that follow, all of which may be prevented by timely attention from now till the leaves fall.

S. D.

COVERING EARLY VINE BORDERS.

MR. SIMPSON asserts that a Vine border, covered early in autumn with non-conducting material, will decline to 50° before Christmas. There is no rule by which this can be properly determined; the character of both surface and sub-soil so far influences the decline of heat that I have found it to vary as much as 7° at the close of the year in different localities. Mr. Simpson mentions instances in which the material laid on merely with the intention of preventing loss of heat had fermented; where this occurred to an appreciable extent, so as to have any influence in heating the border, the operator can have had but little knowledge of the nature and management of protecting materials. Your correspondent is doubtless aware of the determined disposition which heat has to ascend. The fermenting matter is required to get to a higher temperature—and to continue at such to

warm the soil in a way to influence root-action—than would be supposed, as I can affirm by examining and testing the temperature of borders thus covered during winter. As a counterpoise to this view I have very often seen the customary bed of leaves laid on the border in autumn under the impression that the roots were moved thereby, but upon being examined it was found to have never been warm enough to have exerted any influence. Your correspondent says I recommend very different treatment for Vines from that which I advise for plants, and would be glad to know why I make the distinction. So far as the use of heat in this way to the roots goes, I decidedly make no distinction. I have long ceased to use or to recommend the use of bottom-heat to any but a very few species of plants. Surely Mr. Simpson would not treat the Vine, which will live out-of-doors in this country, in respect to heat as he would plants from the hottest part of the world that cannot live without heat. What he says would imply this, and yet to most people the statement will appear somewhat startling. There is no greater mistake committed in gardening than generalising too far and acting on the assumption that because plants of a certain character require such and such treatment, others must do the same. Volumes have been written upon the absolute necessity, in order to insure success, of having the roots in simultaneous action with top growth, both as regards Vines and all other plants subjected to artificial heat. It is an extremely plausible proposition, and those who advocate such doctrine are continually quoting Nature in support of their views, forgetting that with a very great number of plants, especially such as are deciduous, a large amount of top-growth takes place long before the root begins to move. The bottom-heat question in reference to plants in general is a wide one, and, in respect to it, a good deal that has been advanced continuously from time out of mind is taken without question as conclusive. In gardening matters we are all very much disposed to run in the old groove, to keep on doing as we have hitherto done, and as our monitors have taught us. I am, however, ready to admit that in the cultivation of fruit-bearing, as well as flowering and other plants grown for the various purposes of decoration, in the majority of cases the best and most approved methods of cultivation are proved and established beyond question; but in some things it is not so, and this matter of bottom-heat is one. Some eighteen years ago I commenced a series of experiments with a large number of the plants that are usually found in collections requiring artificial heat in which to grow them, and the result is that for the last twelve years I have not used a particle of bottom-heat to any except bulbs for forcing, Oranges, and a very few others, although always having in the houses devoted to stove plants a good body of fermenting matter. I gave up its use, because I found that far the greater number of plants could be grown much better without it.

T. BAINES.

FIG CULTIVATION AT SMYRNA.

THE United States Consul at Smyrna furnishes to an American paper the following account of Fig culture in Asia Minor, for which he is indebted to Mr. Augustus O. Clark, an intelligent Englishman, who settled many years ago in the Aidin district, where he engaged in the manufacture of liquorice paste, and subsequently became a large owner of Fig orchards. The Aidin district, Mr. Clark states, is the only one which produces Figs for exportation. The fruit will grow anywhere in the neighbourhood of Smyrna of a quality for consumption in a green state; but the Aidin plain is unique in its climate and soil as being favourable for the proper curing of the Fig. The thermometer seldom falls below 3° or 4° under the freezing point, and in the summer seldom rises above 130° Fahr. in the sun. In Aidin the winters are generally wet, the dry weather commencing in May and continuing to the end of October. Any rain at the end of July or during the months of August and September, when the fruit is under the process of drying, injures its quality by causing it to burst, hardens the skin, gives the Fig a dark colour, and spoils its keeping quality. Heavy dews will cause the same evils. What is required during the time the fruit is coming to maturity are fine weather and dry winds. The Fig tree grows in almost any soil; it grows very luxuriantly, however, in a rich, heavy soil; but to produce Figs that will dry well and please the merchant, the soil ought to be of a good depth, and of a rich, light, sandy nature; this latter, if the weather be favourable, will produce large Figs of a white thin skin, and of the finest quality. Before planting, the ground ought to be well ploughed two or three times to a good depth, well pulverized, and free from all weeds and extraneous roots.

The Fig is propagated by means of slips, selected with as many fruit-buds as possible. To form a tree two slips are planted, 1 ft. apart, and then joined at the top. The trees, if planted in rich soil, should be placed about 30 ft. apart, and for poor soil about 25 ft. distant from one another. The cuttings should be planted in the

month of March—two in each hole—at about 9 in. or 12 in. apart; then gradually bring the tops to meet, just crossing them, thus, X; then tread in the earth well. The cuttings must be full of buds or eyes, and when about to plant them cut the root end off at the first knot, care being taken not to leave any of the pulp in sight, as it will then be liable to be attacked by worms, which will make the tree hollow and sickly. The cuttings should be put into the ground to within 1 in. or 2 in. of the top, after which the process of crossing must take place. The ground must be well trodden in to within 1 in. or 2 in. of the top, then cover the remainder over with loose earth, which will protect the ends from the heat of the sun. When the trees reach about the height of a man, nip or cut off the tops to one uniform height, and this will cause them to branch out. During the growth of the trees, the ground ought to be ploughed up two or three times during the winter or spring, and the space between them may be used for Broom, Sesame, or Indian Corn. When the trees are large, the same system of ploughing and loosening the earth around them ought to be continued. To make a Fig tree grow well, the ploughing is very essential. If this be not attended to, the fruit will be small and in every respect inferior. The first year of planting, the cuttings ought to be watered during the summer months.

The male fruit, about the middle of June, contains a large number of small flies, and is thrown on the female tree; these flies then get distributed over the fruit and convey the necessary amount of pollen. The system is as follows:—When the female Fig (first crop) is about the size of a Hazel-nut, five or six of the male Figs are strung on to a piece of string, and one or two of these branches are thrown upon the female tree, according to its size and amount of fruit. This operation is repeated when the second crop is about the same size. As the tree grows larger year by year, the number of strings is increased; but more than six strings (say about thirty male Figs) are never put over the largest tree at one time. These strings are put on the tree about one hour before sunrise, and care must be taken that the weather is fine and no wind blowing. I may mention that, if the male Fig be not applied, the crop will not set, but the fruit will fall off; and if too many be applied, the fruit will likewise fall or become very small or inferior.

About the end of July the first Figs come to maturity. The Fig harvest lasts about six weeks. When the Fig is ripe, it will of its own accord fall from the tree, only partly cured. Women and children are employed to pick up the fruit into small baskets, to be conveyed to a place in the garden well exposed to the sun, where they are spread on a bed of dry Grass or matting, singly, and are turned every day, so as to get every side of the Fig exposed to the sun. After a few days of exposure those Figs which are considered sufficiently dry are selected from the mass and divided into first, second, and third qualities. Care must be taken not to dry them too much. When properly cured the skin ought to feel dry, but the inside soft. The grower then sends the Figs to Smyrna, where they are re-sorted and packed for shipment.

FRUIT TREES IN POTS *v.* TREES ON TRELLISES.

My orchard-house has this past week (ending May 5) been a source of unmixed gratification. The terrible east wind, bringing the "envions sweeping frost" in its wake, has destroyed without pity or remorse the budding hopes which I had encouraged of a brilliant crop of fruit out-of-doors—Pears, Plums, Cherries, and Apples; these last, at present undeveloped, are in a woful plight; Peaches, Nectarines, and Apricots are starved with the cold. But, in the orchard-house all this is changed; my trees set with fruit are flourishing and healthy; the tender green shoots have bidden defiance to the cold, and the house, now in its twenty-seventh year, is full of promise, with an abundant crop of fruit of the size of Hazel-nuts, a result which amply repays the original cost of the house and the annual cost of the labour. In order to test all systems, I have within the last few years grown several Peach trees on trellises under glass in the ordinary method: these trees are remarkably healthy and vigorous, and I may, without conceit, say that they are fairly trained; they were covered with bloom, and gave splendid promise of fruit, and I hoped this year that I could at all events arrive at some definite conclusion as to the profitable results of the two systems, but to my astonishment many of the trellis trees have shed their blossoms without fructification; a fair quantity of fruit remains, but not enough. Now the untrained trees in pots and the untrained standards planted out are thickly studded with fruit: it is difficult to account for this great difference. The soil here being very favourable for the cultivation of the Peach and its congeners, I have never until this season been able to realise the difficulties which undoubtedly exist in some

localities. I shall be glad to know if trained Peaches on trellises be generally well furnished with fruit. I have noticed a great scarcity of bees, which in most years frequent my houses in multitudes.

T. F. R.

THINNING PEACH CROPS.

When a Peach tree sets its fruit thickly, the first thinning should be proceeded with as soon as the fruit is fairly set. Do not delay this work till the fruit is stoned, as some recommend, on the plea that the tree is sure to cast a portion of its fruit of its own accord at that critical period, forgetting that exhaustion is the chief cause of a tree dropping its fruit, and that the heavier it is cropped previous to the stoning period, the more likely is it to suffer. It is rarely that a Peach tree casts any quantity of its fruit when thinly set. This I have remarked over and over again, and also noticed that the fruit in such cases was always finer, as might be expected. But a healthy, good-conditioned tree usually sets an enormous quantity of fruit, frequently fifty times more than it can bring to maturity. We hear of extraordinarily abundant sets this spring under glass. In such cases, thinning becomes imperative as soon as the petals of the flowers drop. At this stage the operator cannot tell the good from the bad fruit, or detect the imperfectly fertilised; but he may nevertheless run along the shoots and reduce the clusters of twos and threes to one fruit, disbudding and pinching the young shoots at the same time, and always contriving to leave the foliage beside the fruit or near it. A week or ten days later—or longer when the trees are in cold houses or out-of-doors—he will be able to see what fruit is going to swell; for, though the imperfect fruit remains for some time, and draws nourishment from the tree, it does not increase in size, and it should be rubbed off forthwith and without hesitation, as it will never come to anything. Frequently, when the weather has been dull and unfavourable at the setting period, a large percentage of the fruit is imperfect and of this description. At the same time that this is cleared away, the healthy fruit should also be thinned out to 1 in. or 2 in. asunder, or more if there be plenty of it; and then thinning may be stayed till the fruit is about the size of small Beans or green Gooseberries, when it should be thinned a third time, leaving the fruit about 4 in. apart all over the tree; after stoning they may again, and for the last time, be reduced to 9 in. or 12 in. apart, according to the vigour of the tree. The amount of space allotted to each Peach is commonly reckoned to be about 1 square foot, and no doubt when fine large fruit is desired, this is not too much; but it is more than is usually allowed, and more than is necessary in an ordinary way. I have for years had magnificent Victoria Nectarines from a not very old tree that has always been cropped at the rate of one fruit to every 6 in., as near as could be averaged; but the Victoria is a vigorous grower, and can carry a heavier crop than most other varieties of the Nectarine. On ordinarily vigorous trees, 9 in. will, however, be sufficient for general cropping, and at this rate the fruit ought to be of fair size, but not extremely large. Still, moderate-sized fruit, in abundance and well finished, is preferred for dessert purposes to a scanty supply of large fruit, though the last is undoubtedly the test of high culture. After the thinning has been done, and the trees have been disbudded for the last time, the leaves and shoots should be put aside or pinched wherever there is a fruit, in order to let the light and air play all round it. Shaded fruit is never either so large or so well flavoured as that which has been well exposed from the first. If, however, the shoots be trained thin enough to allow the sun's rays to penetrate freely to the border below or to the wall behind, accordingly as the trees may be placed, the fruit will generally have enough light. In conclusion, it may just be stated that the directions here given apply also to the Apricot and Plum, and all other stone fruits.

CHEF.

Effects of Frosty Nights on Fruit Trees, &c.—It is greatly to be feared that the frost on the night of May 3 may have proved disastrous to the fruit crops in this neighbourhood. The thermometer in the morning on that occasion indicated 9° of frost (23°), and since then the weather has been cold, the wind being in the north-east and snowflakes occasionally falling. Apricots as large as marbles are blackened and destroyed, only those fruits which happen to have been placed between a branch and the face of the wall appear to have escaped. Pear, Plum, and Gooseberry blossoms are exceedingly abundant, but they are just in the state most susceptible of injury and most doubtless have suffered greatly. If, however, less than a tithe of the blossoms escape, there will be plenty for a crop. Asparagus in the open ground here is just beginning to be fit for use, which is about a month later than usual, but every head which has ventured through the soil is killed. Potatoes which were the other day 4 in. or 5 in. high, are now black and lying dead on the surface

of the soil. Some beds of *Dicentra spectabilis* coming into flower are also killed to the surface of the ground. Such are a few of the casualties experienced here, and it is to be feared that our case will not be found to be an exceptional one.—P. GRIEVE, *Culford, Bury St. Edmunds.*

The Weather and the Fruit Crops in East Anglia.—The week ending May 5 was a terrible one for the fruit crops, the wind being in the north-east all the while, with the exception of transitory changes—almost momentary—into the south to what the appetite for more intense cold—frosts from 7° to 12°, according to altitude and locality. On the 4th a few drops of rain attempted to fall and were converted into snow. Peaches, Nectarines, and Apricots have suffered severely; Pears, few of which are fully open, seem yet to be safe. It is too early to write of the effects of the frost on Cherries and Plums in full flower. The promise of a heavy fruit crop is simply magnificent, but the prospect of carrying it safely through is not bright at present. Gooseberries and Currants seem to have escaped here, but in low-lying localities it is feared they have perished. Early Potatoes dressed with Salus for safety against disease have been out to the ground by the frost in their first essays at growth. Early Peas unmistakably show the effects of the late cutting winds.—D. T. FISH.

—Spring frosts and withering winds have been unusually destructive this season. Green vegetables of all kinds have been exceedingly scarce; their growth, in fact, appeared to be paralysed, while that of young crops is unusually slow even in sheltered positions. Fruit trees that at one time promised to blossom early are now very late, which, while frosts and east winds last, is so far fortunate. I have not yet seen an Apple bloom expanded; in fact, some of the late-flowering kinds scarcely show any signs of the buds swelling. As regards seeds of tender crops, where the soil is heavy it is best to defer the sowing until somewhat later than usual, as nothing is gained by hurrying seed into land in a cold, sodden condition.—J. G., *Henham.*

Syringing Vines.—I should certainly object to shutting up and steaming or bathing Vines with water, as is stated (see p. 292), but there is a medium in all things, and especially as regards this matter. I always use the syringe in the Vinery from the time when the house is closed till the fruit is ripe, and my father, who has been a successful Grape-grower for the last forty years, has always done the same, and we are never troubled with red spider or any other insect pest. I syringe freely at starting, and maintain a moist atmosphere until the Vines are in bloom, when I use the syringe more sparingly, but keep the ground and the lower part of the house somewhat moist. As soon as the Grapes are set, I again syringe freely, giving plenty of air. My opinion is that judicious syringing strengthens the Vines, instead of making the wood tender or spongy, as some assert. If "Nemo" (see p. 348) maintains a moist atmosphere, gives plenty of air at top and bottom when the fruit is colouring, does not syringe the bunches after the berries change colour, but simply keeps the ground somewhat moist, leaving a little air on at top all night as well as during the day in dry weather, he will have Grapes of superior colour and flavour, and not be troubled with red spider. I may add that the water used for syringing should be perfectly clean and never below 60°; syringing with cold water is generally followed by bad results.—CHARLES H. KITCHING, *Cokethorpe Park, Witney.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Wash for Fruit Trees.—Mr. Charles Downing, the eminent American fruit-grower, writes as follows on washing fruit trees:—"Why use lime for the trunks and large branches of trees? It has an unnatural and unsightly appearance, while soft soap leaves the bark smooth and of a natural colour, and my experience is that it is more effectual. Potash is equally good. Dissolve each pound in a gallon and a half of water; put it on with a stiff brush, and when no use the brush should be kept in water. The person using it should be careful not to get the potash on his hands and clothes. Soft soap should be put on as thick as it can be used. Any rough bark should be scraped off before washing the trees, and when washed annually no rough bark or Moss will appear."

PLATE LXXIII.

GREIG'S TULIP.

(TULIPA GREIGI).

Drawn by F. W. BURBRIDGE.

THIS handsome early-blooming Tulip is a native of Turkestan, whence it was sent by Russian collectors to the Botanical Gardens at St. Petersburg two or three years ago. Of all the known species of Tulip, and there are some twenty-six described in Vol. V. of THE GARDEN (1874), p. 48, this is, perhaps, the most showy and desirable as a garden plant. It blooms freely in April or May, its large goblet-shaped flowers being generally of a vivid orange-scarlet colour; but there are also purple and yellow-flowered forms of this Tulip. Herr Max Leichtlin, of Baden-Baden, by whom the plant was introduced into commerce, tells us that its bulbs are so extremely hardy that they will withstand freezing and thawing with impunity, and that even when the leaves are half-grown they will endure a temperature as low as that of zero without any protection. The first collector who sent living bulbs of this Tulip to the director of the Imperial Botanic Gardens at St. Petersburg, appears to have been Karolkour, who visited Central Asia in 1872. The plant was at first referred to *T. altaica*, but Dr.

Regel eventually found it to be a new species, and named it *T. Greigi* in honour of General Greig, President of the Imperial Russian Horticultural Union. Having now seen it growing in gardens near London for the last two seasons, I have no hesitation in pronouncing it to be one of the most distinct and precious of all spring-flowering bulbs. The plant is a vigorous grower, attaining a height of from 9 in. to 15 in., each of the stout, erect, puberulous scapes bearing a solitary flower from 4 in. to 6 in. in diameter when fully expanded, and three or four lanceolate, glaucous leaves with undulated margins, the whole of the upper surface being boldly blotched with purple or chocolate-brown. Mr. J. G. Baker states, in the "Botanical Magazine," that during the last two years no fewer than three striking new Tulips have been added to the list of species cultivated in this country. Although they come from different localities, they all resemble one another closely, both from a botanical and horticultural point of view; they are *T. boetica* of Boissier, a native of Greece; *T. Eichleri* of

Regel, a native of Georgia; and *T. Greigi*. To compare them with familiar types, all the three species come between *T. suaveolens* (the common early Duc Van Thol Tulip of gardens) on the one hand, and on the other, *T. oculis-solis* and *T. præcox*. They show the dwarf habit, downy stems, and nearly uniform obtuse, perianth segments of the first, but have the large nearly black basal blotch with a distinct yellow border, which fills up the whole claw of the perianth segments of the last, and gives to the flower its most characteristic mark as compared with *T. Gesneriana* and other common kinds. B.

WISTARIA AND IVY ON RAILINGS.

THE accompanying engraving shows a graceful mode of growing Wistaria and Ivy on railings which may now and then be seen in the neighbourhood of Paris, and which well deserves the attention of those wishing to form ornamental screens on railings, &c. The effect of the Ivy below is, of course, good at all seasons, particularly in winter and spring when the Wistaria is bare. At this season the recently bare shoots of the Wistaria are liberally graced with large bunches of bloom, and frequently there is a second crop in autumn. Forming graceful and enduring, though changeable, little pictures of this sort is that which best repays for expenditure in gardens.

Wistaria and Ivy on railings.

"INSECT-EATING" PLANTS.

SINCE the appearance of Mr. Charles Darwin's book upon this subject some few years ago, the theory of carnivorous or insectivorous plants has created a great deal of interest in the scientific world. A short time afterwards another English botanist published a series of fresh observations, which greatly added to our knowledge of these singular plants. The idea, however, was not of recent origin, and botanists who have taken up this interesting subject are well aware that the foundation of all researches in this direction was laid by Ellis, an English *savant* of the last century, who published his researches as far back as 1768, in which year he informed Linnæus that, according to Bartram the traveller, the *Dionæa muscipula*, a plant growing in North Carolina, was insectivorous. He also communicated to the illustrious Swede his own observations on the irritability and prehensile movement of the leaves of this *Dionæa*, properties which had never hitherto been observed to exist in the vegetable kingdom. In communicating these details to Linnæus, Ellis gave it as his opinion that the plant not only caught and killed insects, but actually fed upon them. This idea was corroborated some sixty years after by an American observer (the Rev. Mr. Curtis), who

Fig. 1. *Drosera rotundifolia* (Sundew).—1. The entire plant. 2. A leaf enclosing in its tentacles an insect placed in the centre. 3 and 4. Structure of the stamens and ovary.

published his observations on the wild plants growing in the marshy prairies of North Carolina in 1834. He remarked that under the irritation caused by the feet of the insects, the two lateral portions of the leaf on each side of the midrib approached each other suddenly and crossed the stiff hairs growing on the edge of their upper surface, and that independent of the act of capture, the leaf exuded a mucilaginous substance, which completely covered the insect, causing it to dissolve and disappear through its corrosive action. Curtis, however, made no converts to his theory, which was treated with incredulity by the naturalists of his day, and it is only since Darwin revived the subject that scientific men have taken any real interest in it. The publication of his researches brought the Venus's Fly-trap into such favour that nurserymen found it difficult to satisfy the demand, and the spongy prairies of North America were ransacked to supply the wants of eager experimentists all over the world. The experiment was simple enough to come within reach of any one. It was merely necessary to place a fly or any animal matter on the upper portion of the leaf in contact with the six little cones with which it is provided, when the two sides of the leaf immediately closed

over the intruding body. Following in the wake of Darwin, botanists fed their *Dionæas* to repletion on flies and other animal food, and the enthusiasm of many of his admirers soon carried them far beyond their masters: Professor Balfour went so far as to declare, that when a toothsome morsel was presented to the leaf its mouth watered, so to speak, the secretion being greatly increased in quantity; while Mr. Canby stated seriously that a forced diet of cheese was prejudicial to the *Dionæa's* system, causing a veritable nausea. The force of enthusiasm could no further go, and the opinions just cited brought about a healthy reaction. Observers began to look about for other plants giving evidence of these natural miracles, as Linnæus called these singular phenomena. Those small and delicate plants, too, known as the Sundews (fig. 1), bear leaves whose upper surface is covered with glandular hairs of a sufficiently complex structure to be considered as part of the leaf itself. Towards the end of the last century a German botanist pointed out that the leaves of the Sundew were capable of catching insects that alighted upon them, and these members of the *Droseraceæ* were placed in the rank of carnivorous plants. As in the case of the *Dionæa muscipula*, flies and pieces of meat are seized and dissolved in a few hours. The glandular processes of the leaves being the main agents in capturing and retaining the insect or scrap of meat, the attention of botanists was more especially directed to those Sundews. The *Pinguiculas* (fig. 2) of our peaty meadows also belong to the class of insect-eating plants. Their fleshy leaves are covered on the upper surface with hairs, some of which are sessile, while others are pediculated, their summits being crowned by a glandular process, formed of radiating cells, not at all unlike a small Mushroom. The following interesting description is from the pen of M. Edouard Morren:— "A small fly, attracted probably by the glutinous appearance of the leaves of the *Pinguicula*, foolishly alights on one of them. From that moment his fate is sealed. He finds himself captured by the feet, which stick fast to the glutinous and downy surface. He struggles in vain to regain his liberty, and even if he succeed in loosening one of his feet, the others stick all the faster. He wears himself out in his vain efforts to escape, and, speedily resigning himself to his doom, falls motionless on his side in the saliva-like liquid, which gradually works into his body, and the poor insect dies a lingering and painful death in the course of several hours. When at last death takes place, the body of the fly is but little altered in shape and roundness, but the next day it begins to flatten, and seems to be glued still more firmly against the leaf, until at last it appears to be incorporated with it. In two or three days almost all vestiges of the insect disappear, nothing being left but the skin." Thus far M. Morren; but our researches ought to be extended further, and all plants provided with leaves in the form of receptacles, or whose surface is glandular, ought to be received into the class of carnivorous plants requiring supplementary nourishment. An American observer, amongst others, put forth the opinion that the *Utriculariæ* were insectivorous plants. The singular structure of their bladders has been the object of constant investigation; here and there at the base of the ramifications of the bladders are little vesicular bodies, which are divisions of leaves transformed into vesicles, as has been proved by M. Duval Jouve. Every one of these little organs is hollow like a sack, its contracted neck being closed by a lid, over which is a crown of leaf-like segments, or a little ring of hairs to guard the aperture. "These bodies," says M. Duchartre in his "Éléments Botaniques," play a physiological part, which increases our interest in them. First of all, they are full of a gelatinous liquid, which is sufficiently heavy to keep them at the bottom of the water, but a short time before the flowering season sets in the aerial canals of the stem convey air to the subaqueous parts of the plant, which, being rootless, rises to the surface of the water and throws out its flowers. The flowering time euded, and the fruit having nearly attained a state of perfection, the air disappears from the interior of the bladders." The transverse blade with which the orifice of the vesicle is furnished, closes it like a valve, and is capable of opening and shutting both inwards and outwards when it is compressed. It is then that the water by which the plant is surrounded forces it downwards to the bottom of the marsh or piece of

water containing it. It has been observed that when the cover of the bladder is open, or forced apart by an insect or crustacean, it is impossible for the animal to escape, so that the interior of these vessels always contains the organic remains of putrefied insects, which apparently help to feed the plant. The genus *Aldrovanda*, the only known species of which is an aquatic plant, one variety of which is found in the stagnant pools of the south of France, is regarded as possessing the same properties, although there is no trap, as in the case of the *Utricularia*; but it must nevertheless be remarked that in both cases the breaking up of the tissues of the animal is performed by the glands with which the walls of the flower are covered, and that absorption of animal matter takes place. "Thus," says Darwin, "every ordinary plant that is provided with viscous glands which accidentally catch insects may, under favourable circumstances, become changed into a species capable of digesting truly." From the *Utricularia*, an aquatic plant (which is not, it is true, endowed with powers of movement like the *Dionæa*, but which is provided with its peculiar sacks or vessels), to aerial plants provided with apparent pitchers there was but one step, for analogy of form seemed to presuppose analogy of function. Plants bearing these receptacles were consequently immediately put under contribution, and Dr. J. D. Hooker, in a remarkable discourse, described his observations on the *Sarracenia*s and *Nepenthes*. There are but few collections of plants, whether private or public, which do not contain representatives of these two genera. The *Sarracenia*s are plants growing in the marshes of North America, of which the species *S. purpurea* is the most commonly cultivated. Their leaves, through an anomaly of development, increase in size at an early stage on the outside of the rim, so that they gradually grow into a boat-like form. According to M. Baillon, the leaves of the *Sarracenia* are almost peltate at the time of their development, but gradually fold their edges over until they assume a tube-like form. The form of this tubular leaf may be imitated by drawing the leaf of a *Nasturtium* through a small tube by means of the petiole. As for the formation of the pitchers of the *Nepenthes*, Dr. Hooker has already given us a long account of it, and it results from his observations that the urn of the *Nepenthes*, instead of being the leaf itself, is a gland situated at the apex of the inner surface of the leaf. This supplementary organ increases in size, the parts become distinct, and the pitcher and its cover are gradually formed. The urns of the *Sarracenia Drummondii* and *S. Darlingtonia* are often of great capacity, and in some cases hold as much as 8 or 9 fluid ounces. The *Nepenthes* are rather more difficult to cultivate than the *Sarracenia*s, owing to their habitat being within the tropics. Their urns are frequently varied in structure, according to the species. Certain of them have pitchers over 1 ft. long, and streaked with different colours. Their edges are often provided with stiff hairs, sometimes even with thorns, the point of which are directed inwards and downwards. The back part being very smooth, we have all the conditions necessary for an efficient trap from which escape is impossible. These urns normally contain a liquid which is said to be secreted by the inner surface of the pitchers; one thing, however, is certain, that the moisture of the air, that of a hothouse, for instance, is condensed and stored up within these receptacles. The presence of insects in these urns, a fact which had been observed by many travellers, was readily taken advantage of by Dr. Hooker, who subsequently proved that the introduction into the urn of inorganic matter produced no appreciable effect, although a piece of animal matter immediately determined a considerable increase in the amount of liquid. He also proved that out of the urn the liquid produced but feeble signs of having digestive properties, while in the interior animal substances were rapidly and completely digested. The *Sarracenia*s and *Nepenthes* may therefore be considered as belonging to the class of insectivorous plants. The only species of *Cephalotus* (*C. follicularis*—Labill.), is a pretty little plant belonging to the *Saxifragæ*. It bears gracefully-formed urns provided with covers, with wings covered with hairs, which curve elegantly outwards from the pitchers. No experiments appear to have been made on this plant, or if they have they are unknown. M. Lemaire, however, in an article on this plant, states that the urns, like those of *Sarra-*

cenias and *Nepenthes*, contain a liquid in which large numbers of insects drown themselves. In the *Dionæa* we have two phenomena which are sufficiently remarkable: the first is the irritation which the mere touch of a fly's feet produces on one of the six glands which are on the upper surface of the leaf; the second, the fact that wind and rain have no action on these glands, except water be projected on them sideways with a certain degree of force. M. C. de Candolle, who has studied the structure of these glands, states that they are formed of the parenchyma of the leaf being one with deep tissues, and that they are not like ordinary hairs, a mere epidermic production. If the epidermis of the leaf be excited, no effect takes place. As soon, however, as the glands are touched, no matter how lightly, the effect is immediately perceptible. This action is immediately communicated to all parts of the parenchyma of the inside of the leaf, which is immediately affected throughout the whole of its interior. Various writers have tried to explain this excitement by the tension and turgescence of the tissues. It is a well-known fact that vegetable cells while growing are provided with a thin skin which is perfectly closed, but which nevertheless has the power of absorb-

Fig. 2. *Pinguicula vulgaris* (Butterwort).—1. The entire plant. 2. Large glands placed on the upper surface of the leaf. 3. Leaves in the form of a rosette, containing the remains of an insect. 4. Leaf, the edge of which has shut over an insect.

ing through its walls the gases and liquids by which it is surrounded; but whether from the immaturity of the cell, or from some other reason which need not be inquired into at the present moment, the younger cells seem capable of absorbing liquid more rapidly than their older neighbours. This phenomenon has been studied in the Sensitive Plant by M. Paul Bert, and M. C. de Candolle explains the phenomena taking place in the *Dionæa* by supposing that the turgescence of the upper layer of the parenchyma of the leaf suddenly ceases when the glands become excited. The upper layer of cells becoming flaccid, the leaf naturally curls inwards like a piece of damp paper held before the fire. On the other hand, the lower surface is alone provided with stomata, and the turgescence of this portion of the leaf is not in equilibrium with that of the upper surface. It follows that the leaf already has a tendency to roll itself. It must also be borne in mind that the valves of the leaf shut in the evening like those of the Sensitive Plant. Be this as it may, we are still perplexed on some points after all those remarkable researches, and even authors themselves acknowledge that there are many difficulties to be cleared up before arriving at the truth. How,

for example, is such rapidity of movement effected? Is not the instability of the tissue affected the real cause of the movement? As yet we have no satisfactory answer.

We now come to the question of the absorption of animal matter by these plants. M. C. de Candolle affirms that for six weeks he has fed *Dionæas* on flies and other insects, morsels of beef, white of egg, &c., side by side with others which have received no animal food, but that he could perceive no difference in the health or appearance of any of the plants. The *Drosera* has been extensively studied by M. Edouard Morren. Here the conditions are somewhat different. The glands with which the upper part of the leaf is furnished secrete a

viscous liquid with an acid reaction. Animal matter is therefore attacked and disintegrated by this liquid, which, in some respects resembles animal gastric juice. The slow movement which is produced in the hairs or tentacles of the leaf from without inwards, whenever a piece of animal matter is presented, would favour the supposition that the plant really requires animal food. The hairs, having bent inwards upon the animal substance with which they have been irritated, remain in perpendicular contact with it, covering it with their acid, viscid secretion. A few hours later on, the albuminous portions of the animal matter become transparent, its angles disappear, and after a day or two but little traces of it are left. What seems so singular is the preference which the tentacles appear to possess for animal matter, while to paper, wax, Elder pith, or any other non-azotised substance, the tentacles appear utterly indifferent; indeed, in some cases the tentacles have been known to bend away from the objectionable object. Mr. Darwin in no way doubts that the glands, which possess the property of dissolving azotised matter, are at the same time organs of absorption. This illustrious naturalist sees the proof of this function in the fact, that azotised matter, especially carbonate of ammonia, induces the aggregation of protoplasm of the upper cells of the tentacle, but the action of ammonia on all plants has long been patent to the whole world. It has also been satisfactorily proved that ammonia is absorbed by the leaves of most plants, especially certain species of *Bromeliaceæ*, which have no roots. The acid liquid secreted by the leaves is stated by Dr. Frankland to contain either propionic or valeric acid. That there is an absorption of azotised matter there can be no reasonable doubt. One chemist fed a *Drosera* on flies which had been soaked in chloride of lithium, and several days after found

traces of that rare metal in all parts of the plant. According to MM. Edouard Morren and Duval-Jouve, the animal matter presented to the *Pinguiculæ*, *Utriculariæ*, and *Aldrovandæ* goes through all the stages of putrefaction, such as the formation of putrefaction, ferments, mycelia of fungi, bacteria, and mycodermis of various kinds. The action of the viscid liquid, however, manifests itself on the albuminous portions of the animal matter, giving them a transparent appearance that seems to indicate the beginning of solution. One of the arguments which militate most in favour of the theory of carnivorous plants is offered by the fact, that animal matter placed on the leaves provided

with glands is preserved for a much longer period than if it were to be placed on an ordinary leaf of the same plant. At a late meeting of the French Botanical Society, when this question was brought forward by M. Heckel, a member observed that there was nothing wonderful that an acid liquid, whether a glandular secretion or not, should preserve animal matter from putrefaction any more than that sound vegetables should be kept free from taint by being immersed in vinegar; but we must also recollect that all acids are not antiseptic in their properties. M. Duval-Jouve, in a most conscientious spirit, has done all in his power to glean the truth from a large number of often contradictory observations made by distinguished naturalists. He has partly refuted the observations concerning the absorptive powers of the glandular surface of the *Utriculariæ* and *Aldrovandæ*, for the reason that these glandular surfaces are to be found on all parts of the plant, and that one part cannot be more absorbent than another. Considering all that has been done by a multitude of observers, we are obliged to acknowledge that the first arguments drawn from them went a little

Fig. 3.—*Arum Draunculus* (one-third the natural size).

too far, while those radical naturalists who totally deny that carnivorous plants exist at all are just as intemperate on the other side. The question of absorption is the true point in dispute. We must not, therefore, be surprised if we find the statements of observers on this point to be often contradictory, more especially as a certain amount of divergence of opinion still exists with regard to the absorptive functions of ordinary leaves and roots. The *Sarracenias* and *Nepenthes* have not given rise to so many bitter disputes as the *Dionæas* and *Droseras*, owing to the absence of the acid secretion, and their claim to a place amongst insectivorous plants has had but few adherents. The liquid they contain is neutral to test paper, and can hardly prefer

traces of that rare metal in all parts of the plant. According to MM. Edouard Morren and Duval-Jouve, the animal matter presented to the *Pinguiculæ*, *Utriculariæ*, and *Aldrovandæ* goes through all the stages of putrefaction, such as the formation of putrefaction, ferments, mycelia of fungi, bacteria, and mycodermis of various kinds. The action of the viscid liquid, however, manifests itself on the albuminous portions of the animal matter, giving them a transparent appearance that seems to indicate the beginning of solution. One of the arguments which militate most in favour of the theory of carnivorous plants is offered by the fact, that animal matter placed on the leaves provided with glands is preserved for a much longer period than if it were to be placed on an ordinary leaf of the same plant. At a late meeting of the French Botanical Society, when this question was brought forward by M. Heckel, a member observed that there was nothing wonderful that an acid liquid, whether a glandular secretion or not, should preserve animal matter from putrefaction any more than that sound vegetables should be kept free from taint by being immersed in vinegar; but we must also recollect that all acids are not antiseptic in their properties. M. Duval-Jouve, in a most conscientious spirit, has done all in his power to glean the truth from a large number of often contradictory observations made by distinguished naturalists. He has partly refuted the observations concerning the absorptive powers of the glandular surface of the *Utriculariæ* and *Aldrovandæ*, for the reason that these glandular surfaces are to be found on all parts of the plant, and that one part cannot be more absorbent than another. Considering all that has been done by a multitude of observers, we are obliged to acknowledge that the first arguments drawn from them went a little

a better claim to being considered a fly-trap than an ordinary bottle half-filled with water. If we once take away the qualification of insectivorous from fly-catching plants, we may at once increase the class beyond all bounds, and the *Silene Armeria*, *Lychnis viscaria*, *Physianthus albens*, *Apoeynum androsæmifolium*, some species of *Erica*, and several others, must all be classed amongst carnivorous plants. The *Aristolochia Clematidis* imprisons any fly that may enter its bell until fecundation has taken place. Certain of the Aroids, the *Arum Dracunculus* (figs. 3 and 4), for instance, are most efficient fly-traps. In *Arum Dracunculus*, the phenomena are somewhat complex. The inflorescence is trumpet-shaped, is

10 in. or 11 in. in length, and 5 in. or 6 in. across the mouth. The livid tint of the inside of the spathe, which is of a dark violet, and the strong and disagreeable odour which it emits, attract flies in swarms; besides this, the interior surface of the spathe is lined with hairs hooked at the end. The strong smell seems to act as a narcotic on the flies, and they die suffocated either by the odour or a certain amount of carbonic acid gas which these flowers produce while in blossom. M. Daveau, of the French Botanical Society, describes two other plants which have never hitherto been considered to be fly-traps, but which have some claim to be placed in that category. One of these is the *Mentzelia ornata*, one of the family of the Loasææ, a native of Texas (fig. 5). It bears a yellowish-white flower measuring about 3 in. across. The whole of the plant, with the exception of the petals, is rough to the touch; this is due to the leaves and stems being thickly covered with hairs of a peculiar structure, as shown at A, fig. 5, but more especially on the outer surface of the receptacle. All the Loasææ are provided with these

hooked hairs, which sometimes have stinging properties, having a bulb at the base containing an acrid liquid like the ordinary Nettle; these hairs, although harmless to man, are fatal to insects. The hairs growing on the *Mentzelia*, which are not stinging, are shown at A, fig. 5; unlike the urticating hairs on other members of the Loasææ family, they are solid, and provided with a number of curved barbs; between these barbed hairs are shorter ones with a soft bulb at the top; this bulb exudes a viscid substance, having a peculiar odour very attractive to flies, which endeavour to taste it by inserting their probosces between the barbed hairs in order to taste the bait. Having sipped their fill, they endeavour to withdraw

their probosces, which are immediately pierced by the barbed hairs. The insect gradually tries to escape by pulling and twisting his proboscis in all directions, generally leaving his head behind him in his frantic efforts to release himself. If a plant of this species be examined on a fine sunny day, the outside of the receptacle is generally found to be partially covered with the heads of flies which have decapitated themselves in their endeavours to escape. Even the smaller diptera do not escape, for the viscid matter of the smaller hairs is of so glutinous a nature that they cannot withdraw their probosces, and perish as miserably as their larger brethren. These plants, although most effective fly-traps, can hardly be called carnivorous, or even insectivorous. Another example is afforded by one of the Aselepiads, *Physianthus albens*, which, according to M. J. Belleruche, a Belgian botanist, performs the same office on butterflies, the trap being this time in the interior of the flower. The *Gronovia scandens* is one of the Cucurbitaceæ, and a native of equatorial America (fig. 6). It is a climbing plant, giving out numerous stems, the stalks and leaves being covered with long, strong, flexible hairs, each terminated by a couple of claws, like those of a cat, which lay hold of everything that touches them. In the Jardin des Plantes, in Paris, several of these plants are cultivated under glass in a hothouse, which is much frequented by small lizards on account of the warmth, but whenever they venture to climb on the *Gronovias* after the flies, which form their natural prey, the claws of the long hairs described above enter the interstices of the lizard's scales, and effectually imprison it. The large lizards generally manage to escape, but the smaller ones often fall victims to their temerity. M. Daveau has counted as many as seven dead bodies in a single day

on one plant. The lizard figured in the cut when measured was found to be 4 in. long.

After the facts cited above one can hardly decide peremptorily on the value of Darwin's theory without assuming a great responsibility. However this may be, it is certain that the observations made during the past few years are frequently contradictory, and that the advocates of the carnivorous or insect-eating theory have been but too frequently carried away by their enthusiasm. It is to be hoped that the researches which are now being carried on by so many naturalists will throw a true and strong light on these mysterious phenomena of vegetable life.—"La Nature."

Fig. 4.—Section of an *Arum* flower, in the interior of which are several captured flies.

GRAFTING AND BUDDING.

In grafting, as in many other operations connected with gardening, mechanical ingenuity cannot of itself, as a rule, insure success; the principles on which it depends must be acquired. I have been led to make these remarks while musing on the instructions which I got as regards grafting in the early days of my gardening career, when, with the regularity of returning spring, we used to march (two of us) with spade and handbarrow into one particular field where clay was to be got. We wanted it tough, and it was not tough, but we spread it out on a brick floor, and we poured water on it to increase its resemblance to putty; into this we battered as much horse-manure as there was clay. This constituted what may be termed the hair of our plaster — at least it served the same end, that is to say, it prevented its cracking and falling off the trees when dry. Then we had our bast to prepare; a can of water accompanied us, and a bundle of grafts from behind a north wall, and then we set out for the grafting ground. Our Apple stocks were in lines $2\frac{1}{2}$ ft. apart; they were, as a rule, about 4 ft. high, and generally thicker than a man's thumb. The first thing done was the cutting over of the stocks at the point at which the graft was to be fixed, generally from 9 in. to 18 in. from the ground. They were cut over where there was a clean straight stem 1 in. or 2 in. below the cut. One row of stocks was thus prepared. Then a stoutish-looking scion was selected. The knife was inserted behind a bud at its lower end, and an endeavour was made to cut in a slanting way right through the scion, the cut being about $\frac{1}{2}$ in. long. The scion thus cut was then placed on the stock, and its cut part marked the spot on which to lay the knife to commence an upward cut on the stock as nearly as possible the same as that on the scion. What we aimed at was, the getting of the inside bark of stock and scion to fit exactly. When that could not be done, we generally contented ourselves if the lower end of the scion fitted the stock that way, and the portion above that fitted at one side. Before fastening it we made a small downward cut, $\frac{1}{2}$ in. in length, beginning $\frac{1}{4}$ in. from the top of the stock. Then to prepare the scion for fitting the stock an upward cut was made in it, beginning fully $\frac{1}{2}$ in. from where the splice was taken off. The scion was then fixed in its place by pushing the tongue of the scion into the cut portion of the stock. It was then carefully bound up with bast and clayed over, the claying process being finished with wet hands, thereby thoroughly completing the graft. Occasionally, by way of variety, they were grafted saddle-fashion. Saddle-grafting is done by cutting the stock into a thin wedge, and fitting the scion over it, which is a very good

way of grafting when scion and stock are of nearly equal diameter. When these scions had begun to grow the clay was removed, and the ties loosened and retied to prevent accidents from wind. In this way I have successfully grafted Apples, Pears, Plums, Cherries (these last are much better budded), Thorns, Ash, Birch, Hollies, &c., in the open air, in all cases just when the buds were going to burst. As already stated, when grafting day came we went behind a north wall for our scions. These scions had been taken off early in February, and were consequently dormant when used. However, I remember we got a large number of coarse-looking Thorns,

the seeds of which came from British Columbia, and which it was determined to graft with scarlet and other fine-flowering varieties. To work we set, and, being late in getting our order, we had to take our scions from the bushes and insert them the same day. Large numbers were grafted under these conditions, and about 50 per cent. failed. The year before we had grafted a few of them and none of them failed; but then we had our grafts taken off six weeks before, and had them behind a wall where they were kept dormant. Roses are grafted in heat; they do not succeed in the open air, because one cannot get Rose scions as one can those of an Apple. Indeed, the Rose is always growing, at least, to a greater extent than an Apple or Pear tree, and the greatest success is when the stocks are forwarded in a little heat, and grafted with scions from the open ground just as they have pushed their buds a little. They are grafted just in the same way as Apples or Pears, and soon push into growth. When fairly united, they should be hardened off gradually. The stock most generally used is the Manetti, although they do very well on the Brier. Inexperienced grafters wanting to try their hand, should strike cuttings of the Manetti, by putting in cuttings in the way recommended for Roses about the middle of September. After growing one year they are fit to graft. For this purpose they should be potted the previous November, and kept in a cold frame through the winter. At the end of January they may be placed in a temperature of from 50° to 60° , when they will soon push, and should be treated as above. Under this system we have been successful in doing them. Rhododendrons and similar subjects are grafted under pretty much the same conditions as the Rose, viz., by starting the stocks in heat. They succeed best in a close, moist temperature, under double glass, as they strike less quickly than most deciduous things.

Budding is a kind of grafting which is generally done in summer, or during the period of growth; the principle of it is just the same as grafting, but smaller portions of it are used

Fig. 5. *Mentzelia*.—(A) The proboscis of a fly captured in the glandular hairs of the receptacle (greatly magnified).

as scions. Many things are budded, but the Rose is the plant on which the inexperienced delight to operate. The time for this is July, or when the buds are fairly plump on shoots that are neither green and sappy on the one hand, nor hard and ripe on the other, and when the bark on the stock rises freely. Whether the operation is on stocks intended for dwarfs or standards, it is mechanically the same. When the operator is ready to begin, let him select such a shoot as I have described; having strands of bast or worsted ready, and a sharp budding-knife, let him fix on the spot where he intends inserting his bud; in standards the best place for this is at the base of shoots which have grown out of the stock this season. The buds should be pushed down to the very base, so that when they grow they may seem to spring from the stock. A cut is made across the shoot, and a longitudinal one from the centre of that in the form of a T an inch or more in length. The bud is removed from the shoot, and any wood

THE KITCHEN GARDEN.

EVILS OF EARLY POTATO PLANTING.

AFTER sharp frosts of from 9° to 10° in severity, accompanied by intensely keen easterly winds for several nights in succession, in what condition are Potatoes that have been planted early, except where very special shelter and care have been afforded? There is not a portion of haulm left above ground, a circumstance which should surely warn people against early planting of Potatoes in general, and of first early kinds in particular, in the hope of securing early crops. It is useless to attempt fighting against insuperable difficulties, and amongst these must be classed sharp, white frosts in May. It is not, however, proposed to prevent growers from starting a few rods early, if they can give them the requisite shelter when needed, but unless that can be done, the seasons show that the chances

Fig. 6.—Lizard captured by the stiff hairs of a Gronovia. (Drawn from Nature, at the Jardin des Plantes).

which is cut with it is removed, being careful to leave heel of the bud—not pulling it out, thus leaving a hole. The bud being ready, it should be pushed down as far as the cut will allow, and the eye should be from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. below the cross-cut. Any portion of the bark which is above this should be cut square across, so that it just fits the cross-cut in the stock. If the shoots of the stock be long and dangling, their points may be removed and the whole left till spring, loosening any ties which may pinch, and re-tying when necessary. In March the ties should be wholly taken off, and the shoots cut back to the bud. Cherries, Plums, Peaches, and a host of other things are propagated by budding.

J. HONEYMAN.

THE FIR AND PALM.

A Pine tree standeth lonely
On a barren northern height;
Slumb'ring, while snows have made it
A covering cold and white.

It dreameth of a Palm tree,
That far in an Eastern land,
Mourneth alone and silent,
On a parched and rocky strand.

HEINRICH HEINE.

are five to one against the Potatoes escaping uninjured. In what year do we not get these keen frosts at some time or other during the blooming of Plums, Pears, or Apples? Even now we are held in suspense with regard to the fruit crops, hoping that the blossoms and young fruits may have escaped the fate which has befallen the Potatoes. We now and then hear notes of praise sounded in favour of autumn planting, that is, about the middle of November. Now it is evident where such a plan is adopted that the haulm would be above the soil early in April, and thus the chances of having it slaughtered by frost would be greatly increased. If there be such an Arcadia anywhere in the kingdom where spring frosts are not known, there let autumn planting be practised by all means; but in other less favoured spots growers should study the seasons, and plant so that there may be a reasonable chance of their Potato crops escaping injury and being properly perfected. I have long been of opinion, and each year's experience supports my belief, that we ought not to commence planting until the

second week in April, and this should be with late sorts, going on gradually to the earliest of all, and if these be got in at the end of April, it is probable that they will not be through the ground until the middle of May, or perhaps a little later, and thus escape frost and the consequent check therefrom. Now that early Potatoes are cut down, those who planted them will find that they have not only stolen no march upon late planters, but further, that of the two they are rather behind. As soon as we get a change of wind with genial rains, the late-planted tubers will throw up their growth with great strength and rapidity, and perfect their crops early. On the other hand, haulm that has been cut down will take some time to recover its growth, which will be comparatively weak; indeed, the gain attending early planting is far more than counterbalanced by the mischief wrought by frost. Potato growers should learn to exercise the virtue of patience, have their seed stocks well hardened and exposed ready for planting at a moment's notice, the soil ready as far as time and weather have permitted, and then get their crops in as far as possible the last week in April and the first in May. A. D.

EARLY FRAME POTATOES.

WE have been lifting Potatoes for these last three weeks, which have been grown as follows:—In the last week in December we mixed together about ten cartloads of leaves and stable litter in equal parts. After letting this lie for a week, it was packed firmly 2 ft. deep, in a large frame covered with glass sashes and heated when necessary with a flue. Soil to the depth of 8 in. was placed on the top of the manure, and the surface when finished was about 2 ft. from the glass. Drills 4 in. deep and 15 in. apart were then drawn, and the sets put in 6 in. apart, and covered over to the original level. In a week the manure underneath was sending up a gentle heat, which it continued to do until the haulms were meeting between the rows. With this assistance they grew very quickly to this stage, and as fire-heat was never applied, and the plants not being far from the glass they did not become drawn or weak. Air was admitted freely during the mild days in March, and they were watered three times—first, shortly after being planted; again, when they were about half grown, and finally about a fortnight before we began to lift them. The soil in which they were planted consisted of about half decayed leaves, and the remainder loam. After the Potatoes have been all lifted, the pit will remain empty for a month or two. About the end of August the soil will be turned over, and the whole will be planted with Dwarf Kidney Beans; these will furnish gatherings until near Christmas; then they will be cleared out, the soil thrown on one side, all the decayed manure removed, when a fresh supply will be at once put in, and the Potatoes planted again. This I consider to be making the best of a large frame, as few vegetables are more acceptable than fresh Kidney Beans in November and December, and ripe new Potatoes in April and May. I find Bresee's King of the Earlies better than any of the Kidney varieties.—J. M.

Vegetable Marrows.—I grow two varieties of Vegetable Marrow, viz., the Large White and the Improved Custard, the seeds of both of which I sow in April. I fill a 6-in. pot with loam and leaf-mould, on which about half-a-dozen seeds are put round the edge, and the pot is afterwards placed in a heat of 60°. In this temperature the young plants soon appear, and as soon as they form the first rough leaf they are potted singly into 4-in. pots, and gradually hardened off until the last week in May, when they are planted out. I have planted them on an ordinary kitchen garden border, but I never had them so fine as I had them once on a heap of garden refuse in a reserve ground. I have also found them to be more fruitful when pretty closely pinched in than when allowed to ramble about as they generally do.—A NORTHERN GARDENER.

Salt for Onion Beds.—Where attacks of maggot are feared on Onion beds, $\frac{1}{2}$ lb. of salt scattered broadcast will do much towards remedying the evil. If the seed be already sown the salt may be applied, but if sowing have not taken place, the ground before being drilled should be sprinkled over with salt, and have a good raking in order to distribute it well. If a slight dressing of salt be applied to Onions after they have made their appearance above ground, it will greatly increase the growth of the plants, as well as help to preserve them from the attack of maggots.—J. S.

The Witloof Chicory.—If this root were plentiful—and there is no reason why it should not be, except for the demand—it might be made both interesting and useful to London people in this way. If five or six roots were put into a pot with a little soil, Cocoa-nut refuse, or sawdust, and an empty nut were turned over it, the roots would push on any window-sill or mantel-shelf. A few days would suffice to bring out sufficient leaf to fit it to be put on the table at breakfast or dinner, to be picked at—"Florist."

CULTURE OF HUMEA ELEGANS.

THIS useful biennial requires to be grown one year as a frame plant in order to prepare it for the second season, when it blooms during the summer and autumn months. The best situation for it is the centre of a large circular bed, or it may be grown in the form of single specimens on the lawn, plunging the pot which it occupies a little below the rim. It is also suitable for a back-row plant in a border, and it is sometimes used for the decoration of the conservatory, its want of showiness in the way of bloom being more than compensated for by its elegant habit. Seeds of it may be sown at any time between the middle of March and the beginning of May. Most people sow it either in shallow pans or in well-drained 6-in. pots, but I prefer sowing it on a gentle hot-bed, along with Balsams, Stocks, and numerous other annuals and biennials that I raise for the embellishment of the flower garden and greenhouse. When the young plants are large enough to handle, I prick them out singly in 3-in. pots, and allow them to remain on the hotbed until they become established. They should be kept as near the glass as possible; air should be given them daily, and water when required. The compost in which they will make rapid growth should consist of three parts turfy loam and one part rotten hotbed manure and leaf-mould, with a sprinkling of silver sand to keep the whole porous. As soon as the roots reach the sides of the pots, the plants should be moved into 5-in. ones, and replaced in the frame. They will not require much water at the roots immediately after they are repotted, but they should be sprinkled overhead, and the frame should be closed early. Under this treatment they will grow strongly and be furnished to their bases with foliage spreading over the rims of the pots. As they advance in growth, they must not be allowed to suffer either from want of water or increased pot-room; but the moment the pots are well filled with roots they should be shifted into pots a little larger in size, employing the same compost, and affording the plants plenty of head-room. Always take care to ensure perfect drainage. By the beginning of autumn they should be established in 9-in. pots, and the plants should be about 18 in. high. The foliage should never be allowed to droop from want of water, but it must not be given until the soil becomes dry; then give as much as will run through the ball of soil and show itself at the bottom of the pot. An ordinary greenhouse temperature will be warm enough for this plant in winter, protection from frost being all that it requires, and even a degree or two below the freezing point will be better than too much heat. It must have plenty of air on all favourable occasions. By the end of February it will begin to grow freely, and should be shifted into 10-in. or 11-in. pots, which will be the last shift required before being placed in the flower garden. About the beginning of April the plants may be moved into cold pits, and the lights taken off during mild weather. Before they are planted out the ground should be deeply dug and made tolerably rich. After planting, give them a good watering, and fasten each plant to a stout stake. If required for the embellishment of the greenhouse, balcony, or verandah, the most healthy-looking plants should be selected and potted into 12-in. pots at the time when the other plants required for the flower garden receive their last shift. Water must be given carefully until the roots strike into the new soil, when they may have manure-water once a week. They cannot have too much light and air, nor can they be kept too cool, provided they are protected from frost. As the growth increases, they will require more room, and they must be turned round occasionally to prevent them from becoming one-sided. If they be kept too close, or in a damp atmosphere, thrips and green fly will soon make their appearance, and these must be checked by occasional fumigations with Tobacco paper. R.

Begonia Incida as a Wall Plant.—This is a free-growing glossy-leaved species of rambling habit, but it is one of the most effective plants with which I am acquainted for draping the back walls of warm plant houses or conservatories. It is readily increased by means of cuttings struck in heat, and small plants of it introduced here and there on Fern-covered walls soon develop themselves, and hang down in bright green wreath-like masses, forming a good contrast to the darker-leaved Ferns and other plants with which they may be associated. It may also be used with good effect as a basket plant.—B.

Black Allium (*A. nigrum*).

Virginian Stock (*Malcolmia maritima*).

Arabian Star of Bethlehem (*Ornithogalum arabicum*).

Twin-flower (*Linnaea borealis*).

Great Speckled Iris (*Iris Susiana*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

LATE-FLOWERING Narcissi are still attractive, especially large beds planted with such varieties as *N. bicolor*, *N. muticus*, and a number of hybrid kinds. Jonquils, are just now at their best, and a very large and free-flowering Narcissus of the yellow Hoop-petticoat Narcissus (*N. Bulbocodium*) is also exceedingly attractive. Either as a rock plant, or for clothing banks or decorating narrow borders, this variety deserves extensive and careful culture; its bright golden funnel-shaped flowers, rising only a few inches above the ground, produce a good display during April and May. Polyanthus Narcissus is likewise in full bloom, and the white flowers of *Anemone nemorosa* are being brought in large quantities to Covent Garden, where they are found to be useful in button-hole and other bouquets. Among Grape Hyacinths several varieties are attractive, notably *Muscari botryoides*, *album*, *pallidum*, and *neglectum*. The rich blue flowers of *Iris biflora* are now abundant, as are also those of the dwarf-growing *I. pumila*. *Epimedium* in variety are flowering freely in sheltered situations, and the large-blossomed Thrift (*Armeria cephalotes purpurea*) is beginning to open its rosy-purple blooms. The bright blue flowers of *Gentiana verna* may now be seen even in Loudon, at Pine-apple Place, and the white Wood Lily (*Trillium grandiflorum*) is in full beauty in places where it is sheltered from the cold east winds which we have lately had. The bright scarlet flowers of *Anemone fulgens* may still be gathered, and several of the Columbines are fast coming into flower. *Aubrietia Hendersoni*, a bright purple kind, is now very attractive. To these may be added *Helonias bullata*, *Saxifraga palmata*, and several varieties of *Orobus*; the *Alliums*, too, are throwing up strong heads of bloom, as are also Globe-flowers, Primroses, Pansies, and Forget-me-Nots.

S.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Flower Garden.—Where a flower garden is filled during the winter with spring-blooming plants such as *Violas*, *Daisies*, *Aubrietias*, *Arabis*, and the like, there is generally a reluctance to move them, which results in the summer-bedders being delayed in planting, through which the effect they ought to produce is considerably diminished, as if not planted at the proper time (even with the best attention afterwards) they fail to get properly established, and, consequently, there is a great lack of flowers in the garden until the season is far advanced. Without going to this extent, the spring-flowering plants may be allowed to remain wholly or in part until within a few days of the time when the summer-bedders should be planted. Where shrubs have been used for beds through the winter, these should be taken up at once and consigned to their summer quarters in the reserve garden, digging over the beds and adding manure in proportion to the impoverished state of the ground, and the species of plant with which each individual bed is to be filled. Those plants of vigorous habit that are more disposed to the production of foliage than flowers, when planted in good soil should have comparatively little manure added to the soil in which they are grown; while others of a less vigorous character must have the ground made richer. In dry, sandy soils in which many bedding plants, especially *Calceolarias*, are with difficulty kept in a healthy condition through a dry summer, manure of a cooler, moisture-holding nature, such as that obtained from cow-sheds, should be used in preference to the drier stable-manure, but whichever is used, let it be sufficiently decomposed; cow-manure particularly, before digging in should have lain in a heap for twelve months, and during that time ought to have been turned over several times; when fit for use it should be nearly black in colour, for if in a crude state, the roots of any plant would not enter it. For strong, heavy soils, there is nothing better than the material of which last year's hotbeds were made, with which a good quantity of leaves has been mixed; this, from its light, open nature, helping to correct the close, adhesive character of the soil. In cases where the beds have been in existence for many years, and during the time have received no further assistance than an annual dressing of manure, this in time ceases to be effective. Summer bedding plants are rapid growers, gross feeders, and may be termed a very exhausting crop, and if spring-flowering plants be put into the ground directly they are removed, the nourishing properties of the soil will be still further lessened. In such cases it will be necessary at times to either wholly or partially renew the beds with

new soil, which will be found to have a marked effect on the flowering capabilities of the occupants. There have been few springs in recent years wherein the ground was so cold and little calculated to promote growth in tender or half-hardy plants as the present, and it will be much better to defer a little later the planting of everything that cannot well withstand cold. If put out before there is sufficient warmth in both the soil and atmosphere they retrograde instead of progressing, getting into a stunted condition from which it takes a considerable amount of hot weather to remove them; on such seasons beds that are not planted until the end of May are often much forwarder by midsummer than those that were filled sooner. Where the carpet system of bedding is adopted, *Sedums*, *Pyrethrums*, and the hardiest *Echeverias* should be at once put in their places, leaving the other portions that are to be occupied by tender subjects, to be completed later on. *Centaureas* and *Calceolarias* also may now be planted, as there is rarely any frost after this time likely to injure them; where the ground is at all dry see that the *Calceolarias* are well watered when they are put out, and that they never afterwards through the summer are allowed to get dry; the cause of their dying off suddenly during the summer is generally attributable to the roots having become dry. *Pelargoniums*, *Verbeucas*, *Heliotropes*, *Ageratums*, *Petunias*, *Lantanas*, *Lobelias*, and *Mesembryanthemums* should have the lights of the frames they occupy tilted night and day when there is no appearance of frost, or drawn completely off during the day in fine weather, so as to harden them in a way that they will receive no check when fully exposed in the beds. If well supplied with water so as to keep them growing, they will be better than if planted out for ten days from this time. *Alternantheras*, *Coleas*, and *Iresines* should be kept in a growing temperature with enough air to make them stout and robust; there is nothing gained by planting these before the end of the first week in June; where there is a deficiency, they may still be propagated. Plants of a sub-tropical character, such as *Aralias*, *Abutilons*, *Hamea elegans*, *Ficus*, *Chamaepeuce*, *Wigandias*, *Cannas*, and any of the greenhouse species of *Palms* that are used for summer decoration out-of-doors, should always receive especial attention, so that they may be gradually and sufficiently hardened before being planted out; where this is not effectually done before they are fully exposed, in a few days they assume a bronzy-yellow, sickly appearance, which it is impossible afterwards ever to set right during the season. It is most desirable to intermix subjects possessing handsome leaves with fine, distinct habit amongst ordinary bedding plants, but they should always present a healthy appearance, otherwise the object in view is defeated. *Dahlias* should be kept where they will gradually develop until the time they are planted out at the end of the month; to ensure this they must not be confined in too small pots, for if the roots become matted for want of room, the stems get stunted and hard, after which they never are equal to plants that have not been in that state.

Gladioli.—Another planting of these should now be made; they will come in to succeed the earliest, and if a few bulbs be kept out of the ground until the last week in the month and then planted, they will bloom late and be very useful for greenhouse and conservatory decoration; they should be lifted and potted about the end of September. The bulbs are the reverse of being benefited by this late planting; consequently it is not advisable to use scarce or dear kinds for this purpose, many of the common, inexpensive sorts being just as good for general display. The objection to planting these most beautiful hardy plants in conspicuous places in beds by themselves is that they are late in coming into flower, till which time the beds are unattractive, not harmonizing well with others in flower; by sufficient forethought this may be obviated if the *Gladioli* be planted somewhat further apart, say 15 in. each way, which will leave room for the intervening spaces to be occupied by *Violas*, *Pansies*, *Palox Drummondii*, *Asters*, *Mignonette*, dwarf *Tropæolums*, or anything of similar character, not planted too thickly so as to interfere with the growth of the *Gladioli*.

The Reserve Ground, that is to be occupied during the summer months by spring bedding plants that have already done duty in the flower garden, should be prepared for their reception, so that there may be no delay in putting them in when taken out of the beds, for if their roots be allowed to dry up before replanting they suffer considerably. The soil is no better for being very rich, as such plants as those under consideration, when frequently moved, are best not grown too luxuriantly, but it ought to be of a light nature, so that the different subjects grown can be taken up without much breakage of their roots; if it be naturally heavy, it will be improved by the addition of sand, leaf-mould, exhausted tan, or anything of a similar nature. Plants that are used for spring bedding should not be too large, as they are much more effective when small and employed in greater numbers; where any are becoming too large, it is better to divide them at the time of their

transfer to the reserve ground than in the autumn when they are being put in the beds. Supply them with water as required until they get fairly into growth. Amateurs with either large or small gardens should have a corner set apart for this and similar purposes. Here also ought to be turned out bulbs that have been forced in pots, such as Crocuses, Tulips, and Narcissi, and any of a similar character, which, after having another year's growth, will have recruited their strength from the exhausting influences of previous forcing; thence they can be transferred to the herbaceous borders.

Celery.—It will be well, if there be sufficient ground at liberty, to make the whole of the Celery trenches ready at once, as this will give an opportunity for growing Lettuces or Spinach on the ridges during the summer, which will be cleared off before the earthing-up process commences. Ground on which has been grown Winter Broccoli, Kale, Winter Spinach, or Turnips, will be suitable for Celery. Under the impression that it saves time, the ground is often cleared of the crop by which it has been occupied, and the trenches opened without digging the spaces between; this is an objectionable practice, and in the end involves more labour, as the nudging ground, covered up by the soil of which the ridges are composed, is in a hard, partially-imperious state, through having remained undisturbed during the autumn and winter, and when it has to be used for earthing up the Celery, it requires a great deal of breaking to make it sufficiently fine. The trenches may be made wide enough for two rows for the earliest crop that is intended for use before winter; but all that is wanted to stand after Christmas will keep much better confined to single rows, as when soiled up, the ridges are much more pointed at top, throwing off the water better than it is possible to make them where double rows are planted.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

May 14.—Potting winter-flowering Carnations, Musk, and shifting Egg-plants into 10-in. pots; also re-potting young Cyclamen plants. Basking Phalanopsis. Sowing French Beans in pots for transplanting under glass covers and under the protection of a south wall; also planting Seakale thongs, Violets, and more Lettuces. Pricking out main crop of Celery into cold frame. Getting manure ready for Mushroom bed. Digging and raking flower borders not already done. Thinning Grapes as fast as they are ready. Turning walks in flower garden in order to kill weeds and give the gravel a fresh appearance. Sticking Peas that are above ground. Hoeing among Potatoes, Carrots, Beet, and Herbs, and digging out more Celery trenches.

May 15.—Potting and staking old Fuchsias, and shifting Balsams into flowering-pots. Potting off Syon House Cucumbers. Re-potting *Dendrobium speciosum* and *thyrseiflorum*. Sowing Marjoram, Sweet Basil, Neapolitan Cabbage and Paris White Cos Lettuces. Planting Lily of the Valley, Tree Carnations, and Anne Boleyn Pinks; also beds of Asparagus, and more Cauliflowers and Lettuces. Putting in cuttings of *Clerodendrons*, *Aphelandras*, and Fuchsias. Putting Azaleas in second Vivary to make their growth, stopping shoots of late Vines, nailing leading shoots of Apricot and Peach trees out-of-doors. Plunging *Rhododendrons* and Lilacs. Raking Rose beds.

May 16.—Potting Cockscombs that are showing bloom; also other kinds of Celosia. Potting off Legg's Melons, small Begonias, and other fine-foliaged plants. Placing *Dendrobium Falconeri* and *Aërides roseum* on blocks. Sowing Primulas, Cinerarias, Calceolarias, and Globe Amaranthus; also Mignonette under verandah and round Rose trees. Planting Sweet Briers, *Dentzia scabra*, *crenata*, and *gracilis*, *Dicentra spectabilis*, and April-sown Lettuce. Putting fresh cinders on East Indian Orchid-stage. Watering Melons, Violets, and young Celery plants. Stopping all shoots on Fig trees. Putting *Alternantheras* for bedding out in cold pits to harden. Earthing up Cauliflowers. Keeping orchard-house rather moist. Thinning fruits of Apricots for the first time. Tying Peach trees.

May 17.—Shaking out and re-potting Cattleyas that are in bad health. Potting Primulas and a few Fuchsias intended for large specimens; also Phlox Drummondii. Sowing Picotees, Mandevillas, Zinnias, Japanese Maize, and Tropæolums of different sorts for baskets; also sowing Cannas, Sweet Peas, Ten-week and Intermediate Stocks, Wallflowers, and Champion of England and Veitch's Perfection Peas. Planting Pansies, Lavender, Gladioli, Stocks, and Asters. Setting Melons that are in flower. Watering and mulching all Apricot trees. Filling Melon-pit and putting in ridge of soil.

Earthing up Vegetable Marrow ridges. Potting Standard Chrysanthemums. Pulling up spring annuals that have ceased flowering. Giving seed-beds a little guano. Thinning Carrots and Turnips. Putting Castor-oil plants for bedding into cold pits. Taking up Tulip and Hyacinth bulbs from flower-beds.

May 18.—Potting Azaleas, Daturas, and a few large Scarlet Pelargoniums for the autumn decoration of the conservatory. Potting off seedling Humeas, Portulacas, and Balsams. Potting *Calanthe veatifolia*. Sowing *Amarantus melancholicus* and *elegantissimus*, and pots of Mignonette. Washing Vines for red spider. Digging land for Turnips and Broad Beans. Manuring places in flower garden in which to plant Purple King Verbena. Hoeing among all growing crops, and staking Peas and Scarlet Runners that require it.

May 19.—Potting *Hedychium Gardnerianum*. Sowing Perpetual and Round-leaved Spinach, Broad Windsor Beans, and more Lettuces, Mustard and Cress, and Radishes. Planting hardy Azaleas in American garden; Sweet Peas raised in pots in well-manured ground; also planting Tritomas, a frame of Sweet Basil, and putting out Cauliflower plants in manured trenches. Re-filling and planting flower vases. Cutting down Sage plants. Clipping *Cerastium tomentosum*. Bedding-out Feverfew, and tying Pelargoniums and Fuchsias. Earthing-up Potatoes. Gathering caterpillars from Gooseberry trees. Putting all bedding annuals out-of-doors. Taking down and stowing away wall tree protections. Dusting Carrots with lime and soot.

Notes on Hardy Flowers.

AURICULAS.—The great bulk of the show varieties should now be in bloom, and some of the earliest will be shedding their flowers; the latter require water only sparingly. If some seed be required, a few of the very best kinds should be set aside for the purpose, and should not be allowed to carry more than three or four pods. In order to have the seed of the fine-edged Auriculas as true to character as possible, the flowers should be kept away from the Alpine varieties. Some of our most successful cultivators will not grow a single Alpine Auricula for fear of tainting their strain. As the prevailing cold, north-easterly winds have necessitated keeping the plants somewhat close, they are very apt to become infested with green fly, and require to be cleansed from it. An artist's brush passed over the leaves occasionally will be found of service.

CHRYSANTHEMUMS.—The cold, retarding weather is showing its effect on Chrysanthemums in pots, and they need all the encouragement possible just now. The plants that are at all backward should be placed in the greenhouse, or be kept in a cold frame and somewhat close till they get a good start; the stronger and more forward plants need not be kept so close, but they should be sheltered from cold winds, and on no account be allowed to suffer from want of water. Stopping must be done as required; now is the time to lay the foundation of good blooming plants in the autumn, and vigilance should be the motto of the cultivator.

CLEMATIS.—All are now making a rapid growth, and attention to training is necessary. In conservatories the shoots of the spring-flowering varieties, whether the plants be in pots or trained to walls or pillars, should be so tied in as not to hide the buds that are already expanding; on no account cut away these shoots, as they will yield flowers next year. The stronger summer-blooming varieties need to be so trained as to fill the space required to be covered: the better the growing shoots are displayed, the finer will be the show of bloom in July. As soon as hot, dry weather sets in, mulch with manure, and give occasional waterings with manure-water. Messrs. G. Jack, man & Sons, of Woking, are now exhibiting Clematises at the Royal Botanic Gardens, where all the best varieties can be seen to advantage.

DAHLIAS.—The young struck plants should be potted on as required, and kept in a frame to make growth. It is scarcely safe to plant out till the first week in June, and that gives the plants time to grow to a good size, and become well hardened. The dwarfier and more bushy the growth in the young plants, the better are they for planting out. The ground intended to be planted with Dahlias should be trenched and a good dressing of manure applied.

DAISIES.—Beds of double Daisies are now in the full flush of their beauty, and their effectiveness is prolonged if the beds be occasionally examined and the dead flowers removed. This facilitates a succession of bloom, besides tending to keep the beds smart in appearance. The new variegated White Globe should be made a note of for use next spring; it is very fine indeed, and is superior to all the variegated forms bearing white flowers.

DELPHINIUMS.—Strong plants which have been in the ground all the winter will now be greatly aided in their growth, if the soil be loosened about them and receive a mulching of short manure and

leaves. A bed of the finer varieties should now be made; and this will be found an effective manner of growing these fine perennials, as it enables the several kinds to be compared the more readily. A deep loam well enriched with manure and leaf-mould makes an admirable bed, and as the plants come into flower, they are materially assisted by a surface mulching of manure. There are now a number of beautiful new varieties well deserving cultivation.

PYRETHRUMS.—These fine hardy decorative plants are commencing to grow, and as snails and slugs are apt to eat the foliage they should be looked after. The enjoyment of all such plants is enhanced by having a bed filled with various sorts, and now is a good time to make one. Those who have limited garden space might grow a few Pyrethrums in pots; they are easily managed, and are well suited to a cold greenhouse. It is a mistake to overpot them, in fact, many plants are thereby spoiled.

POLYANTHUS.—Choice varieties in the open ground will be greatly benefited by having the flower-stems removed, adding a top-dressing of some good soil. Any good varieties in pots may be ranged under a north wall on an ash bottom, or planted out in a prepared bed for the summer. The Gold-laced varieties, being much later, are now in full bloom. The named kinds are of somewhat delicate constitution and need special treatment. To yield good flowers they should be well established in pots; and when they have ceased flowering they also can be planted out. Those potted in the spring should remain in the pots all the summer, and be kept in a cool moist place. In saving seed from any particular variety, be content with two or three pods, and do not exhaust the plants by overtaxing their energies. A sowing may be made as soon as the seed is sufficiently ripe.

PEONIES.—These are now growing strongly, and should have every encouragement. Towards the middle of the month the flowers will be expanding, and as they invariably do so at a critical time when frosts may be looked for, a little protection should be given where possible. Some cultivators adopt the practice of syringing just before the sun gets on the flowers.

TULIPS.—Beds of these glorious flowers look uncommonly well this season, that is, where the beds have received adequate attention. The flowers will be late this season, and what the plants really require are warm sunshine and soft genial rains. A mulching with manure will do good and greatly assist the plants. They must be protected from the wind, as the flower-stems are apt to be snapped off.

VERBENAS.—Struck cuttings of Verbenas should be grown on as quickly as possible, and hardened off for going out into flower-beds at the end of the month. A little seed may now be sown in a gentle bottom-heat, to supply a late batch of flowering plants. D.

Town Conservatories.—I have seen a conservatory belonging to Mr. Anderton situated amid the smoke and dust of this town. I have visited it from time to time this spring, and when everything was cold and bleak without it was one mass of charming flowers, consisting of Hyacinths, Tulips, Chorozemas, Azaleas, Spiræas, Deutzias, Lily of the Valley, Roses, Rhododendrons, and many more, which rendered it different from anything of the kind in this township. Such a house, indeed, is more like a flower show than a conservatory. There are scores of houses that do not deserve the name of conservatory, inasmuch as so far as flowers are concerned I could bring them all away in my hand. What, however, one man can do under difficulties, so ought another; we cannot all live in the pure air.—JOHN WATSON, *Bradford*.

The Hull Botanic Gardens.—Mr. Niven, the curator of the Hull Botanic Gardens, lectured on them at the Royal Institution, Hull, on Saturday afternoon, before a large audience, Dr. Gibson presiding. In a pleasing conversational manner, the lecturer told the story of the origin of the present garden in 1811, and of its increase in the course of time from two acres to six. He stated that when first opened the garden was, so to speak, quite in the country, there being few houses within a considerable distance. He spoke of the connection of Messrs. Watson, Kirby, Spence, Heyworth, and Parker in the early history of the garden, and then coming down to twenty-five years ago, the period when he became curator, he referred to the wretched condition of the garden at that time, and said that the place more resembled a hayfield than a botanical institution. He alluded to the visit to Hull at that period of the British Association, in anticipation of which the scientific men of Hull bestirred themselves, and the garden was all at once resuscitated. He traced the many vicissitudes of its history from that time, and alluded to the laudable efforts of the late Mr. Moss, Alderman Bannister, and others to sustain and improve its character, to the gradual diminution of its usefulness through obvious and irremediable causes, and

then to the present intentions of the proprietors with regard to its sale, and next to the projected new garden, the plans for which he exhibited, lucidly explaining their many interesting details.—At the close, the chairman complimented Mr. Niven on his lecture, and remarked upon the great attention with which his remarks had been listened to, and upon the motion of Mr. Micks, a hearty vote of thanks was accorded to the lecturer.

Climber-covered Trees.—Last year, while grubbing up an old shrubbery for alterations, my men carelessly cut through the main root of a large Wych Elm, and the long dry summer following the accident killed the tree. Will you suggest some good climber that would not only get up the trunk but also cluster in the branches? Will anything grow successfully besides Ivy—there being many other trees round it, though it stands open to the south? I am loth to cut it down, and fancy it could be made ornamental.—W. A. [There are many plants suitable for your purpose, but the following require but little trouble after they are once planted. Clematis Vitalba or common Virgin's Bower would do well under such conditions, as would also the Virginian Creeper, especially if the soil at the foot of the tree where it is to be planted be enriched with a barrow-load or two of well-rotted manure. Either green-leaved or variegated Ivies would, of course, do well, but for graceful summer tree drapery we know of nothing equal to the hardy climbers just named.—ED.]

The Late Show of Orchids held at South Kensington.—I exhibited at the Royal Horticultural Society's show on the 2nd inst. a collection of Orchids, for which the Floral Committee awarded me a large silver medal; but by some mistake your report appears to have given Mr. Bull, who had a small collection placed close to mine without sufficient separation, the credit of exhibiting my plants. I had forty-five Orchids in flower, amongst them the *Odontoglossum Roezli*, which you noticed on April 4, but which now has twenty-two expanded flowers, and several buds; also a large plant of *Cypripedium caudatum* with seven spikes—ten expanded flowers and five buds; and *Odontoglossum novium* with eight spikes. The *Phalcnopsis Luddemanniana*, *amabilis*, and *grandiflora*, and the *Cypripedium niveum* were also mine.—J. G. HEBURN, *Sidcup Place, Kent*.

Protection of Fruit Trees in Pots.—Mr. T. Francis Rivers writes to us from Sawbridgeworth on this subject as follows:—"The disastrous frosts of the past week amount nearly to a national calamity, but they will have the effect of stimulating fruit growers to the introduction of schemes for the better protection of fruit. Glass-houses are, of course, the most efficient protectors that can be devised, but they are not within the reach of all. I have, I think, found a method that is within reach of most persons at a small expense. Having observed that tender plants in pots may be preserved during severe frost by laying them on the ground and covering them with mats or canvas, I potted several Pear trees last autumn; they have stood through the winter without protection, and were covered with stout and well-conditioned blossom. When the dour east winds gave notice that a heavy visitation of frost might be expected, the trees were placed in a position to occupy a small compass when laid down. On the evening of Wednesday week, a dozen trees of the finer sorts of Pears, each capable of bearing three or four dozen fruit, were simply laid down and covered with mats. I am happy to say that they have successfully passed through the heavy ordeals of the frosts of Wednesday, Thursday, and Friday, the mats being removed during the day, the trees remaining recumbent. After the necessity for protection is passed, which we may fairly hope will arrive before midsummer, the pots should be plunged in a border over the rim and the surface of the soil covered with loose manure. Little water will be required, and if the sides of the pots be perforated to allow the emission of roots into the surrounding soil, the trees will be entirely self-supporting, and may remain in the same position until the next inclement spring returns. The plants when required will submit to the excision of the roots outside the pot without injury. A few dozen Pear trees will give a good supply of fine fruit, and with good cultivation will amply reward the cultivator."—"Times." [It is much to be desired that some really efficient means of protecting grown Pear trees be devised. On walls, a wide temporary coping does all that is required, but we have never seen any really efficient and inexpensive means of protecting pyramid trees.]

Figs Under Glass.—I shall be much obliged for some practical advice upon the management of Figs planted in the borders under glass with and without artificial heat. I am chiefly doubtful as to whether, when Figs are forced, the second growths should be stopped. I take it for granted that the first shoots should be stopped after three or four leaves have been developed. It seems to me doubtful whether the shoots of Figs that are not forced should be stopped at all, lest the young growths should fail to ripen.—A SUBSCRIBER. [In the case of Figs forced under glass, the stopping of the shoots

when three or four leaves have been developed is the practice generally followed with both the first and second growths. The proper thinning-out of the shoots where too thickly placed is likewise another operation that needs attention, for the Fig requires plenty of light and sun-heat for the fruit to be high-flavoured. The best crops of Figs are produced when forced under glass with artificial heat, where the roots of the trees in the borders are confined and under control, so that a surface-dressing of manure can be given them at times, as well as liquid manure when swelling their first and second crops. In managing Figs under glass, but without being forced, the stopping of the shoots is likewise necessary, and if the roots be circumscribed in the border, there will be no danger of the wood not ripening. Where the roots of the trees ramble over large rich borders the young shoots get too gross and succulent, and so prove unfruitful from the wood not being properly ripened.—WILLIAM TILLERY, *Wolbeck.*]

Drury Lane Garden.—A correspondent writes:—"Last week it was announced that a burial ground long since disused in Drury Lane had been formally opened as a garden by the vicar and churchwardens of the parish of St. Giles for the use of the surrounding inhabitants. The gardens had been neatly laid out, planted with shrubs and deciduous trees, and furnished with seats similar to those in use on the Thames Embankment. However, on the evening after the opening, the churchwardens went down to see how the garden was appreciated, when they witnessed such a scene of disorder, wanton trampling on the ornamental grounds, and, in some instances the tearing up of plants and shrubs, that immediate orders were given to have the gardens cleared and the gates closed until further notice." [No very great damage was, however, done. In forming such gardens at first it is much better to begin with trees only, which cannot be easily injured; flowers, or Grass, or shrubs, can only be grown with great difficulty and expense in such an atmosphere; besides, playgrounds are more needed than gardens. A gravelled space with trees would be a great gain in many densely-populated districts; it might also be a beautiful feature amidst buildings.]

Loam and Peat in Italy.—Although loam is so extensively employed in plant culture in England, it is not so indispensable as is often imagined. On the Continent it is comparatively but little used, and in many horticultural establishments, where plant culture is carried on with great success, loam is scarcely known. There the staple articles for the majority of soft-wooded plants are well-rotted manure and thoroughly decomposed leaf-mould. In France the former is called *terrain*, and if properly prepared, it is admirably adapted for the production of all quick-growing plants. I have myself used it for Gloxinias, Achimenes, Cinerarias, Pelargoniums, Dracenas, Ficus, and many kinds of Palms, with the best results. It should, however, be at least four or five years old, and turned over until brought into the consistency of mould; in this way it can be used even in a pure state for many plants with perfect safety. If Mr. Powers have not this at command, he could probably obtain it and the leaf-mould from a nurseryman in his neighbourhood. Hard-wooded plants of comparatively slow growth, such as Deutzias, Cytisus, Oranges, &c., are the better for a mixture consisting of some more tenacious soil; probably Mr. Powers could obtain some burnt earth, which is so much used in South Germany, and which is probably also known to the Italian plant-growers; with these ingredients at hand loam may be dispensed with. A substitute for peat is not so easily obtained; there are, however, but few plants that demand its exclusive use—of these the principal are Heaths, Epacris, and some other New Holland plants. Many tender stove plants, for which pure peat is commonly used, will succeed in leaf-mould, taking care to pot lightly, and ensure perfect drainage.—J. CORNHILL, *Byfleet.*

NATIONAL AURICULA SOCIETY'S NORTHERN SHOW.

This took place in the Town Hall, Manchester, on Friday, April 27, and though owing to the lateness of the season several exhibitors were prevented from competing, there was nevertheless an interesting display, the specimens staged being on the whole very good. The leading class was for six varieties, one at least of each of the four sections into which Auriculas are divided being shown. Of these the best collection came from the Rev. F. D. Horner, Kirkby Malzeard, who staged fine examples of green edge—Booth's Freedom and Trail's Anna; grey edge—George Lightbody, and Lancashire Hero; white edge—Smiling Beauty; and self—C. J. Perry. Second, Mr. B. Simonite, Rough Bank, Sheffield, showed green edge—Talisman and Prince of Greens; grey edge—Lancashire Hero and George Lightbody; white edge—Frank Simonite; and self—Spalding's Metropolitan. Other fine flowers shown in this class were green edge—Imperator and Oliver's Lovely Ann; grey edge—Ringleader; white edge—Richard Heady, True Briton, and Taylor's Glory; self—Pizarro and Lord of Lorne. In the class of four varieties, one in each

class, the Rev. F. D. Horner was again first with green edge—Anna; grey edge—George Lightbody; white edge—John Simonite, a new variety; and self—Meteor Flag. Second, Mr. B. Simonite, with green edge—Lovely Ann; grey edge—William Bradshaw; white edge, John Simonite; and self—Pizarro. Some other good flowers in this class comprised green edge—Barlow's King, a good old variety, sometimes caught in fine condition; grey edge—Rev. George Jeans and Privateer; and white edge—Boud's Perfection. In the class for pairs a goodly number of plants were staged, the best being grey edge—C. E. Brown; and white edge—Smiling Beauty, from the Rev. F. D. Horner. Next came grey edge—General Bolivar; and self—Pizarro, from Mr. T. Mellor, Ashton-under-Lyne. Third, C. Roys, Esq., Rochdale, with green edge—Prince of Wales; and dark self—Ellen Lancaster. In the classes for single plants a great number of plants were staged. The premier green edge was Lancashire Hero, a grey-edged Auricula properly, but which sometimes comes green, when it can be shown as such; then followed in the order of merit Imperator, George Lightbody, Colonel Taylor, Prince of Greens, and Seedlings. The premier grey edge was George Lightbody, and following this came Lancashire Hero, Dr. Horner, Samuel Barlow, C. E. Brown, General Bolivar, Complete, and Alexander Meiklejohn. In the white edge class that lovely flower Smiling Beauty was awarded the premier position; and following this came Alma, Beauty, Smith's Ne Plus Ultra, Richard Dean (a very promising seedling raised by Mr. B. Simonite), John Simonite, Fanny Crossland, and Ann Smith. The premier self was Othello, finely shown; then followed Pizarro, Ellen Lancaster, Meteor Flag, Lord Clyde, Mrs. Sturrock, Lord of Lorne, Sims' Eliza, and Bessy Bell. Prizes were also offered for the best Lancashire Hero, which was won by the Rev. F. D. Horner; the prize for the best grey edge was awarded to George Lightbody, shown by Mr. B. Simonite; and the best green edge, was found in Booth's Freedom, shown by the Rev. F. D. Horner. Alpine Auriculas made a very pretty display, and in the north the competing varieties must all be edged or shaded flowers, selfs not being admissible. The best four were shown by Mr. R. Gorton, Eccles, and consisted of Diadem, Ovid, Beatrice, and Dolly Varden; Mr. S. Cooper, of Timperley, came next with the three first named and Dazzle. Other good Alpines were Mauve Queen, conspicuous, Neatness, Fair Rosamond, George Lightbody, and Elcho. But little need be said respecting the Polyanthuses. Only the old Gold-laced varieties were permitted to compete, and of these the display was decidedly meagre; the leading varieties were Cheshire Favourite, Exile, Lord Lincoln, President, and George the Fourth. D.

THE WIND AND THE WAR.

WHAT is that white on yonder trees?
Pear-blossom. Ugh! It might be snow;
So bitter, hard, the eastern breeze;
And the thermometer so low.
I see white petals of the Pear,
But Apple trees of pink are bare.
Late Apple, due in early May,
And Lilacs shrink from coming out.
A haze bedims the orb of day,
And influenza flies about.
And not one Jack, in wonted green,
On this bleak May-day has been seen.
Bees keep their hives, too wise to hum
In such hard times from flower to flower;
Cuckoo and nightingale are mum,
In holes and crannies swallows cower,
Wondering where spring-time can have fled,
Till cruel May frost nips them dead.
May, more than commonly severe,
Too well this woful east wind suits,
That comes the opening leaves to sear,
And shrivel up the swelling fruit.
Two bitter things—nigh on a par—
Are eastern wind and Eastern war.

—"Punch."

QUESTIONS AND ANSWERS.

Names of Herbs.—Having been busy this month renewing our bed of Sweet Herbs of which we have a good store for supplying the Blind Asylum (particularly with nasegays), I feel sure that there are several possessing a sweet smell that we require to complete our collection. Can any of your readers tell me what is "galingale" and "setuale," both mentioned by Spenser in his charming description of a "gay garden" and "of everie flower and herbe there set in order?" *Fide* "Maipotimus; or, the Fate of the Butterflie," p. 195.—F. J. HORG, *Wardie Lodge.*

Hybrid Primroses.—Would you kindly inform me whether a hybrid between a Primrose and a Cowslip is of frequent occurrence or not, as I have come across a wild plant having all the characteristics of both? Its leaves are short, like those of the Cowslip, but the blossom is that of three Primroses on one thin stalk. The colour is just intermediate between the two.—W. T. B. *Oxford.* [Your plant may possibly be the Common Oxlip, which is, according to Darwin, a natural hybrid between a Cowslip and a Primrose, and which has the leaves of the former and the flowers of the latter, borne Cowslip-fashion several together on a tall scape.—Ed.]

Polyanthuses.—"For Mr. William Cudwell, Wallingford" (see p. 367), read "Wallingford Street, Wantage."

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

ODONTOGLOSSUM VEXILLARIUM.—There is a large group of this in beautiful bloom in Mr. Bull's nursery at Chelsea. Seen in all stages of blossom, and in considerable variety, this plant here proves itself even more lovely than it was thought to be at first. Although the flowers are so large, they are so delicately coloured that when seen in quantity, gracefully floating over the light green leaves, they call to mind coloured Primroses on a mossy carpet in a copse, or an Alpine meadow jewelled with flowers, rather than effects usual in Orchid-houses.

IMPORTED BANANAS.—At one time—and but half-a-dozen years ago—these were little more than a curiosity in the market; now they are in almost general request, and their use is spreading greatly. They usually come to the London market from Madeira. When they arrive in a green or unripe state they are kept in warm cellars, where they ripen well, before being offered in Covent Garden.

PELARGONIUM DUCHESS OF BEDFORD.—Messrs. Beckwith, Tottenham, send us blooms of this beautiful white Pelargonium, which is now also beginning to be in demand in Covent Garden. It is a beautiful decorative and table variety, raised from Digby Grand, with fringed petals, two delicate dots of colour on the upper petals, the rest being pure white. It is very early, dwarf and firm in habit, free in growth, and under good cultivation makes a sturdy free-blooming plant in one season.

PRIZE PLANTS AT SLOUGH.—On Monday last, Mr. Charles Turner extemporised an exhibition of many of his well-grown show plants. Many noble specimens were in the nursery ready to start for various exhibitions on the following day. These made up a "show" of pot Roses, Pelargoniums, and Azaleas such as could not elsewhere be seen. The long Rose-house, with its avenue of enormous Rose "trees" in pots, was especially remarkable for its beauty. From it came the plants which were so much admired during the past week at the Crystal Palace, the "Botanic," and Manchester shows. The proceeds of the exhibition were given to the Parish Church Enlargement Fund.

THE PLANES IN THE GREEN PARK.—The relief of some of these by thinning was effected during the winter, and the trees promise to afford a noble shady grove for one side of Piccadilly in good time. It is to be hoped the rest will shortly be thinned also. A very fine line of young trees has also been planted alongside the drive in Hyde Park. They are planted at distances which will admit of their becoming stately trees, and affording pleasant shade.

LAMARQUE ROSE IN COOL HOUSES.—This is a lovely Rose for planting out in a greenhouse or any cool house; a plant put out in one of the cool houses in the Royal Nurseries, Slough, now bears a crop of delicate white Roses overhead. It is very free and very graceful, and the buds are valuable from having a good clear hue from their earliest appearance. It forms a charming contrast to *Maréchal Niel* planted out in the same house.

MAGNOLIA FUSCATA.—Few plants have flowers that yield so strong a scent as this variety of Magnolia, sometimes called in nurseries *Fuscata pinnata*. One partly expanded blossom on a small plant of it in the large conservatory at Pine-apple Place literally fills the house with fragrance. When the large numbers of other flowering plants that occupy the same house are taken into account, it is surprising that the scent of this one small blossom should be so markedly apparent.—C. S.

THE TREES OF PARIS.—François Miron, Administrator of Public Works in the reign of Henri IV., was the originator of planting trees in the streets and public squares of Paris. He commenced by planting a distance of 6000 ft., and paid a third of the cost out of his private purse. There was lately to be seen in the courtyard of the Deaf and Dumb Asylum, Rue Saint Jacques, a large Elm, perhaps one of the finest of its kind in Europe. Its height was 50 metres, and its circumference, just above the ground, 5 metres. This was the last tree planted by him. Since that time the plantations of Paris have multiplied. The trees planted on the interior Boulevards are estimated at 91,137; those of the Boulevards around Paris, 11,411; on the quays, 4,706; in the avenues, 6,872; in the squares, 3,659; in the streets, 1,864; in the Champs Elysées, 9,555; on the Esplanade of the Invalides, 2,040; near the slaughter-houses, 1,510;

near the granaries, 994; in the cemeteries, 3,826; in the playgrounds of the Communal Schools, 1,130. The right bank of the Seine possesses 29,536 trees, that of the left, 22,642. Although trees of less than fifty years of age are far more numerous, there are, nevertheless, 12,500 aged from seventy-five to 100 years and upwards.

IXIAS IN COVENT GARDEN.—Either in beds, out-of-doors, or in pots for conservatory decoration, *Ixias* are very effective, and their blooms are also valuable in a cut state. Large quantities of a bright scarlet kind, highly appreciated by bouquet makers, have been coming into Covent Garden Market for weeks past, from the Channel Islands.—S.

NARCISSUS POETARUM.—Mr. Ware sends us blooms of this pretty *Narcissus*, in which the whole of the cup is bright orange. Every lover of gardens must be pleased to see how much sought after the various forms of the Poet's *Narcissus* now are.

HYDRANGEAS IN POTS.—There are many plants of these now growing in the Clapton nurseries in 4-in. pots, with heads of bloom 15 in. in diameter. We have never seen such large heads springing from short single stems.

ROSE SHOW AT THE ALEXANDRA PALACE.—We hear that a large Rose Show will be held at the Alexandra Palace on Saturday, 30th June, for which a liberal schedule is being prepared. The schedule will shortly be ready, and may be obtained on application to Mr. John A. McKenzie, 1 and 2, Great Winchester Street Buildings, E.C.

GRASS IN LONDON.—The "Echo" calls for more Grass in the garden in Drury Lane:—"Many a country nobleman throws open his park to his neighbours, and they do no injury. They sit or amuse themselves under the trees. He knows their habits of life and acts in accordance with them. Gentlemen of the Vestry, do the same! Give your little subjects a little more Grass and a trifle less gravel, and you will find the duties of the 'imposing attendant' considerably abridged and your own pleasures greatly augmented." We merely quote this to point out that growing Grass in such a position is wholly impracticable. Trees, and shade, and seats are all that are really possible at present in such positions. While the trees are young, however, it is desirable to furnish such places with other materials temporarily.

THE BANKSIAN ROSE.—A plant of this Rose is now in full bloom here. It is trained against a wall facing the south, and it is so distinct and lovely that every one who has accommodation for a climbing Rose should have a plant of it. Its blossoms, which are lemon-coloured and produced in clusters, remind one, as far as size is concerned, of those of a double Cherry; yet they possess the very shape of the most perfect Rose. The choicest flowers indoors are not more valued in a cut state than these, and an ordinary-sized plant will produce handfuls of flowers for weeks in succession. This Rose should be pruned as soon as it has done blooming, when the new wood formed during the autumn will bloom luxuriantly about this time next year.—A NORTHERN GARDENER.

DALE TESTIMONIAL.—As would be seen by an advertisement in our columns last week, a committee has been formed for the purpose of presenting a testimonial to Mr. Joseph Dale, of the Middle Temple Gardens. Mr. Dale, so long ago as 1811, began to ornament the gardens of the Middle Temple with *Chrysanthemums*, and his annual exhibitions of them show what may be done with that flower by judicious treatment, even in the heart of smoky London. The present is therefore considered to be a fitting opportunity for *Chrysanthemum* growers to show their appreciation of Mr. Dale's labours. Communications on the subject, or donations, may be forwarded to Mr. Shirley Hibberd, Hermitage Road, Stoke Newington, Treasurer; or to Mr. J. S. Hodson, Gray's Inn Chambers, 20, High Holborn, Secretary.

NATIONAL HORTICULTURAL EXHIBITION AT MANCHESTER.—The Grand National Horticultural Exhibition at the Botanical Gardens, Old Trafford, which commenced yesterday the 18th inst., and will be continued as usual during the whole of Whit-week, will, we are glad to find, be of a nature deserving of the popularity which has been accorded to this interesting show in previous years. Extensive as the gathering has been in recent years, it has been found necessary this season to increase the space devoted to exhibits, the schedule being on a larger scale and the entries more numerous. Provision has been made for tender exotics in the spacious glass exhibition house, whilst the large annexe will be filled with Rose trees in full flower, *Rhododendrons*, *Azaleas*, *Pelargoniums*, Tree Ferns, Palms, *Lomatias*, *Cycads*, *Alpines*, and new hardy trees and shrubs. In an additional tent erected on the north side of the exhibition house, will be placed collections of plants of many kinds "arranged for effect." Grouping being here the test of merit, this department will probably excite a good deal of interest, more especially as it is a new feature in the exhibition.

COVERING EARLY VINE BORDERS.

ALLOW me to say, in reply to Mr. Baines (see p. 378), that Vines like other plants, require a root temperature about equal to the mean temperature of the atmosphere in which the leaves and branches are developed. This I base upon my own experience, the experience of others, and the almost universal law of Nature in that respect, a law to which Mr. Baines himself adheres in his plant culture, for I do not suppose he keeps the roots of his plants in one house and the tops in another. If this treatment be correct, then I say it cannot be afforded to early Vines with their roots outside, if the border be covered with non-conducting materials only. The temperature of the border will be very far indeed below the mean temperature of the house, when heat is most needed at the roots. On this point I have no two opinions, if one can trust one's eyes and a good thermometer; and it lies with Mr. Baines to show either that such a temperature is not proper for Vines, or that a layer of non-conducting materials is sufficient to secure it. To one or other of these positions he is committed by the advice which he gives at page 312, and which, I think, is misleading. I still adhere to my statement that the temperature of outside borders is about 55° or 60° early in the autumn, and it will continue steadily to decline from that period under a covering of non-conducting materials only, and by non-conducting materials I mean such as are available in gardens, that is, dry leaves or straw, covered with wooden shutters or thatch to throw off the wet. Put on sufficient materials to ferment, however, and you wrap the warm ground in a warm blanket and keep it warm, which is what all cultivators use fermenting materials for—they are simply a means to an end. I trust I have made myself clear to your correspondent, and I feel sure that he is far too practical a man to fight shy of the question at issue. I am perfectly well aware that Grapes can be grown, even though the above conditions be not conformed to strictly, but the best plan is the best for everybody, and the nearer they are fulfilled the better. Mr. Baines makes remarks concerning the "volumes that have been written" on the subject of bottom-heat, and about much that has been advanced "time out of mind" being accepted "without question as conclusive," &c. The only reply that I would make to this is, that it is much to be regretted Mr. Baines did not give the public the benefit of his long experience in Vine culture, and also an account of the "series of experiments" which he made eighteen years ago with the avowed object of testing this vexed bottom-heat question, when there was so much discussion about it, and when his opinions would have been of practical value. It does seem strange that one having such matured opinions on the subject should have allowed the most fitting opportunity of expressing them to pass by, for I do not remember that at the time referred to Mr. Baines had a word to say on the subject.

J. SIMPSON.

Wortley.

When to Water Vines.—"A Northern Gardener" (see p. 362), in contradistinction to those who advocate giving manure-water to Vines only when the fruit is swelling, says that he gives it from the time when the shoots are from 1 in. to 2 in. long up to the colouring point as regards the fruit. I go further than that, and advocate it being given every time water is requisite; and having practised this for years with a fair amount of success, I can recommend it for adoption by others. Grape Vines are gross feeders, and when in good health it is almost an impossibility to give them too much nourishment. I would recommend their diet to be varied occasionally, as, for instance, from guano-water to soot-water, or ordinary liquid-manure from the stable or cow-yard.—A SOUTHERN GARDENER.

Fruit Blossoms and Spring Frosts.—Most disastrous results may be expected from the severe frosts which occurred on the first days of this month, and which culminated on the morning of the 5th by the sharpest frost known in May for some years past, viz., from 9° to 15°. One need not ask how fruit-blossoms have fared—our worst fears are realized. In the midst of the havoc it is, however, refreshing to direct attention to any trees that have escaped, though ever so narrowly. Such we have in a row of low cordon Pears which are trained obliquely to iron hurdles, and which were covered when frost seemed imminent with Frigi Domo; in the case of these every blossom has escaped injury. Now, considering the uncertainty of our climate, and the ready mode of protecting such trees as are here named, is it not worth the consideration of planters as to whether cordon or espalier training should not be more largely adopted? Mr. Rivers' suggestion as to growing bush or pyramidal trees in pots, laying them on their sides, and protecting them with mats in frosty weather, is also worthy of consideration, and though, personally, I have a horror of all kinds of pot fruit culture, I am willing to admit that a dozen Pears, even, from a pot plant, are better than none at all, which, from very many trees, will be the case this season.—W.

EXHIBITION OF CLEMATISES.

MESSRS. JACKMAN & SONS have this year, as heretofore, afforded a treat to all lovers of Clematises who have an opportunity of visiting the Royal Botanic Gardens, Regent's Park. These plants, numbering nearly 250, are arranged in the form of a sloping bank extending the whole length of the corridor which adjoins the conservatory. Clematises are beautiful under all circumstances, but when seen as we find them here, their true value as decorative plants can be fully appreciated. They are trained over balloon-shaped or pyramidal wire trellises, which are covered with flowers of all shades of colour, so arranged as to harmonize well with each other. This exhibition is edged with silvery-leaved Euonymuses and Lithospermum prostratum, and standard scarlet-flowered Rhododendrons in full bloom are inserted at certain distances apart amongst the Clematises with good effect. Of Clematises we noted fine plants of Lord Derby, a variety with fall and well-formed flowers of a pale lavender or bluish-mauve colour; Sir Garnet Wolseley, bluish with dark purple anthers; Countess of Lovelace, a vigorous-habited kind, bearing a profusion of flowers of a bluish-lilac colour; Lucie Lemoine, also a charming kind, with pure white, rosette-shaped blossoms. A variety named The Gem, with brilliant mauve-coloured flowers, was especially striking; and Duke of Richmond, a whitish-pink-flowered kind, with rosy-purple veins, was in equally good condition. S.

Raising Seedling Chrysanthemums.—I have now coming into bloom a plant of Chrysanthemum Orange Annie Salter. It was started with a number of others at the proper time in order to bloom for seedling purposes, and judging by the appearance of the bud (just colouring) I shall have a very fine bloom, although only in a 5-in. pot. In 1875 I started a quantity of Chrysanthemums with the view of getting some seed, and amongst others Mrs. Moggeridge produced me a splendid pod, the contents of which being later than I had hoped for were not sown till this year. I have now some fine seedlings, well-established in 5-in. pots, which will in due course be shifted into blooming-pots the same as the named varieties. Those which I flowered last year were very promising. Seeds cannot be had from November blooms; therefore I have had recourse to the plan of obtaining flowers in spring, and then seed. I may add that I keep them thoroughly cool during the blooming period.—F. T. Davis, Plumstead Common.

Fertilising Aucubas.—Some have been tolerably successful in getting plants of the Aucuba well furnished with berries by planting a male Aucuba beside one of the opposite sex, or by grafting the two together; and I have also seen berries upon bushes without any male plant being near them; but fertilising a few female bushes each day while they are in flower would be time well spent. Indeed, a good Aucuba well covered with berries is as ornamental a plant as could be desired, and fertilising is an operation easily done when once it is tried. We have one small male plant here, and last season, when its flowers were fully open, I gathered some and fertilised the flowers of our female Aucubas with them, and the result is that they are now producing some very pretty red berries; whereas, had I not used the male flower as described, the probability is that we should not have had a single berry.—R. M.

Lilium giganteum.—There may now be seen at Hospitalfield Gardens, Abrecht, a specimen of this Lily with a flower-stalk 7 ft. high, on which are eleven fine blooms. Has this been beaten elsewhere?—G. PATON, 21, Nethergate, Dundee.

Hyd Park.—A useless walk between the drive and the Knightsbridge Road has been very properly done away with. Pending greater reforms one of the most useful works to which students of landscape gardening could devote themselves, would be the abolition of unnecessary walks.

May Frosts in Suffolk.—The late severe frosts have been very destructive in this district. Plums, Pears, and Cherries blossomed abundantly, but hardly any have escaped unhurt; all the early blossom on Apples is destroyed; of Apricots and Peaches on a south wall none are left; Gooseberries and Currants are very much thinned. The early blossoms of Strawberries are black in the heart, but with good weather we may still have a fair crop. Walnut trees look as if they will hardly recover—their young shoots are all destroyed.—F. DODDS, Millthorpe.

Weather in South Lincolnshire.—The following will give some idea of the kind of weather which we have lately had in this district:—

May 1	22 degrees	cold, with hail and wind	Wind N.
" 2	35 "	cloudy	" N.W.
" 3	39 "	cold, with hail	" N.
" 4	24 "	cold, with snow and hail	" N.E.
" 5	27 "	cold, with hail	" N.E.
" 6	24 "	clear, frost	" N.E.
" 7	23 "	"	" N.E.
" 8	23 "	"	" S.E.
" 9	35 "	thunder, and rain	" S.E.
" 10	41 "	thunder-storm, with heavy rain and hail: ½ in. fell in four hours: weather since more settled.	

—D. LUMSDEN, Blenheim Hall.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 372).

Ivy.

- (1) *Titanic*. The female Ivy so
Enrings the barky fingers of the Elm.
Midsummer Night's Dream, act iv., sc. 1.
- (2) *Prospero*. That now he was
The Ivy which had hid my princely trunk
And sucked my verdure out on't.
Tempest, act i., sc. 2.
- (3) *Adriana*. If ought possess me from thee it is dross,
Usurping Ivy, Brier, or idle Moss.
Comedy of Errors, act ii., sc. 2.
- (4) *Shepherd*. They have scared away two of my best sheep; if any-
where I find them 'tis by the seaside browsing on Ivy.
Winter's Tale, act iii., sc. 3.

The rich evergreen of "the Ivy never sear" (Milton) recom-
mended it to the Romans to be joined with the Bay in the
chaplets of poets—

Hanc sine tempora circum
Inter victrices hederam tibi serpere lauros.—*Virgil*.
Sen condis amabile carmen
Prima ferēs hederæ victricis præmia.—*Horace*.

And in mediæval times it was used with Holly for Christmas
decorations. But the old writers always assumed a curious
rivalry between the two—

Holly and Ivy made a great party
Who should have the mastery
In lands where they go.

And there is a well-known carol of the time of Henry VI.,
which tells of the contest between the two, and of the mastery
of the Holly; it is in eight stanzas, of which I extract the last
four—

Holly he hath berries as red as any Rose,
The foresters, the hunters, keep them from the does;
Ivy she hath berries as black as any Sloe,
There come the owls and eat them as they go.
Holly he hath birds, a full fair flock,
The nightingale, the popinjay, the gentle laverock;
Good Ivy, say to us, what birds hast thou?
None but the owlet that cries "How, how!"

Thus the Ivy was not allowed the same honour inside the
houses of our ancestors as the Holly, but it held its place out-
side the houses as a sign of good cheer to be had within. The
custom is now extinct, but, formerly, an Ivy bush (called a
tod of Ivy) was universally hung out in front of taverns in
England, as it still is in Brittany and Normandy. Hence arose
two proverbs—"Good wine needs no bush"—i.e., the reputa-
tion is sufficiently good without further advertisement; and
"An owl in an Ivy bush," as "perhaps denoting originally the
union of wisdom or prudence with conviviality, as 'Be merry
and wise'" (Nares). And the Ivy was a plant as much
admired by our grandfathers of the fifteenth and sixteenth
centuries as it is now by us; Spenser was evidently fond of it—

Amongst the rest the clambering Ivie grew
Knitting his wanton armes with grasping hold,
Least that the Poplar happily should rew
Her brother's strokes, whose boughes she doth enfold
With her lythe twigs till they the top surwey,
And paint with pallid greene her buds of gold

Virgil's Gnat.

And Chaucer describes it as

The erbe Ivie that groweth in our yard that mery is.

And in the same poem he prettily describes it as

The pallid Ivie building his own bowre.

As a wild plant, the Ivy is found in Europe, Asia, and Africa,
but not in America, and wherever it is found it loves to cover
with its close and rich drapery, old walls and buildings, and
trees of every sort, and where it once establishes itself it is
always beautiful, but not always harmless. Both on trees and
buildings it requires very close watching. It will very soon
destroy soft-wooded trees, such as the Poplar and the Ash, by
its tight embrace, not by sucking out the sap, but by prevent-
ing the outward growth of the shoots, and checking—and at
length preventing—the flow of sap; and in buildings it is no
doubt beneficial as long as it is closely watched and kept in

place, but if allowed to drive its roots into joints, or to grow
under roofs, the swelling roots and branches will soon displace
any masonry, and cause immense mischief.

We have only one species of Ivy, and there are only two
real species recognised by present botanists, but there are
infinite varieties, and many of them very beautiful. These
variegated Ivies were known to the Greeks and Romans, and
were highly prized by them, one especially with white fruit
(at present not known) was the type of beauty. No higher
praise could be given to a beauty than that she was "hedera
formosior alba." These varieties are scarcely mentioned by
Gerarde and Parkinson, and probably were not much valued;
they are now in greater repute, and nothing will surpass them
for rapidly and effectually covering any bare spaces.

I need scarcely add that the Ivy is so completely hardy that
it will grow in any aspect and in any soil: that its flowers are
the staple food of bees in the late autumn, and that all the
varieties grow easily from cuttings at almost any time of the
year.

Kecksies.

Burgundy. And nothing teems
But hateful Docks, rough Thistles, Kecksies, Burs,
Losing both beauty and utility.
Henry V., act v., sc. 2.

Kecksies or Kecks are the dried and withered stems of the
Hemlock, and the name is occasionally applied to the living
plant.

Knotgrass.

Lysander. Get you gone, you dwarf.
You minimus, of hindering Knot-grass made,
You bead, you Acorn.
Midsummer Night's Dream, act iii., sc. 2.

The Knot-grass is the *Polygonum aviculare*, a British weed,
low, straggling, and many-jointed, hence its name of Knot-
grass. There is no doubt that this is the plant meant, and its
connection with a dwarf is explained by the belief, probably
derived from some unrecorded character detected by the
"doctrine of signatures," that the growth of children could be
stopped by a diet of Knot-grass. Steevens quotes Beaumont
and Fletcher to this effect, and this will probably explain the
epithet "hindering." But there may be another explanation.
Johnstone tells us that in the north, "being difficult to cut in
the harvest time, or to pull in the process of weeding, it has
obtained the sobriquet of the Devil's-lingels." From this it
may well be called "hindering," just as the *Ononis*, from the
same habit of catching the plough and harrow, has obtained
the prettier name of "Rest-harrow."

But though Shakespeare's Knot-grass is undoubtedly the
Polygonum, yet the name was given to another plant, for this
cannot be the plant mentioned by Milton—

The chewing flocks
Had ta'en their supper on the savoury herb
Of Knot-grass dew-besprent.—"Comus."

In this case it must be one of the pasture Grasses, and may
be *Agrostis stolonifera*, as it is said to be in Aubrey's "Natura
History of Wilts" (Dr. Prior).

Lady-smocks.

Song of Spring. When Lady-smocks, all silver-white,
Do paint the meadows with delight.
Love's Labour's Lost, act v., sc. 2.

Lady-smocks are the flowers of *Cardamine pratensis*, the
pretty early meadow flower of which children are so fond, and
of which the popularity is shown by its many names, Lady-
smocks, Cuckoo-flower, Meadow Cress, Pinks, Spinks, Bog-
spinks, and May-flower, and "in Northfolke, Canterbury
Bells." The origin of the name is not very clear. It is gene-
rally explained from the resemblance of the flowers to smocks
hung out to dry, but the resemblance seems to me rather
far-fetched. According to another explanation, "the Lady-
smock, a corruption of Our Lady's-smock, is so called from
its first flowering about Lady-tide. It is a pretty purplish-
white, tetradynamous plant, which blows from Lady-tide till
the end of May, and which during the latter end of April
covers the moist meadows with its silvery-white, which looks
at a distance like a white sheet spread over the fields" ("Circle
of the Seasons.") Those who adopt this view called the plant

Our Lady's-smock, but I cannot find that name in any old writers. Drayton, coeval with Shakespeare, says:—

Some to grace the show,
Of Lady-smocks most white do rob each neighbouring mead,
Wherewith their loose locks most curiously they braid.

And Isaac Walton, in the next century, drew that pleasant picture of himself sitting quietly by the waterside—"looking down the meadows I could see here a boy gathering Lilies and Lady-smocks, and there a girl cropping Culverkeys and Cowslips."

There is a double variety of the Lady-smock which makes a handsome garden plant, and there is a remarkable botanical curiosity connected with the plant which should be noticed. The plant often produces in the autumn small plants upon the leaves, and by the means of these little parasites the plant is increased, and even if the leaves are detached from the plant and laid upon moist, congenial soil, young plants will be produced. This is a process that is well known to gardeners in the propagation of Begonias, and it is familiar to us in the proliferous Ferns, where young plants are produced on the surface or tips of the fronds; and Dr. Masters records "the same condition as a teratological occurrence in the leaves of *Hyacinthus Ponzolsii*, *Drosera intermedia*, *Arabis pumila*, *Chelidonium majus*, *Chirita sinensis*, *Epicia bicolor*, *Zamia*, &c."—"Vegetable Teratology," p. 179).

Lavender.

Perdita. Here's flowers for you,
Hot Lavender, sweet Mints, Savory, Marjoram.
Winter's Tale, act iv., sc. 3.

The mention of Lavender always recalls Walton's pleasant picture of "an honest ale-house, where we shall find a cleanly room, Lavender in the windows, and twenty ballads stuck against the wall, and my hostess, I may tell you, is both cleanly and handsome and civil." Whether it is from this familiar old-fashioned picture, or from some inherent charm in the plant, it is hard to say, but it is certain that the smell of Lavender is always associated with cleanliness and freshness. It is not a British plant, but is a native of the south of Europe in dry and barren places, and it was introduced into England in the sixteenth century, but it probably was not a common plant in Shakespeare's time, for though it is mentioned by Gerarde as growing in his garden, it is not mentioned by Bacon in his list of sweet-smelling plants. The fine aromatic smell is found in all parts of the shrub, but the essential oil is only produced from the flowers. As a garden plant it is found in every garden, but its growth as an extensive field crop is chiefly confined to the neighbourhood of Mitcham and Carshalton in Surrey, and there at the time of the picking the flowers, and still more in the later autumn when the old woody plants are burned, the air for a long distance is strongly and most pleasantly impregnated with the delicate perfume.

Laurel.

- (1) *Clarence.* To whom the heavens in thy maturity
Adjudged an Olive branch and Laurel crown
As likely to be blest in peace and war.
3rd Henry VI., act iv., sc. 6.
- (2) *Titus.* Cometh Andronicus bound with Laurel boughs.
Titus Andronicus, act i., sc. 2.
- (3) *Cleopatra.* Upon your sword
Sit Laurelled victory.
Antony and Cleopatra, act i., sc. 3.
- (4) *Ulysses.* Prerogative of age, crowns, sceptres, Laurels.
Troilus and Cressida, act i., sc. 3.

This is one of the plants which Shakespeare borrowed from the classical writers; it is not the Laurel of our day, which was not introduced till after his death, but the *Laurea Apollinis*, the *Laurea delphica*,

The Laurel meed of mightie conquerors
And poets sage.—*Spenser*.

that is the Bay. There can be little doubt that the Laurel of Chaucer was the Bay, the

Fresh grene Laurer tree
That gave so passing a delicious smelle
According to the *Eglantere ful wellle*.

though the Laurel in Lyte's Herbal (the *Laurel* or *Lourye*) seems to be the *Daphne Laureola*. But unconsciously Chaucer and Shakespeare spoke with more botanical accuracy than we do, the Bay being a true Laurel, while the Laurel is a Cherry (see Bay).

Leathercoat (see Apple).

Leek.

- (1) *Thisbe.* His eyes were green as Leeks.
Midsommer Night's Dream, act v., sc. 1.
- (2) *Pistol.* Tell him I'll knock his Leek about his pate upon Saint Davy's Day.
Henry V., act iv., sc. 1.
- (3) *Fluellen.* If your majesties is remembered of it, the Welshman did goot service in a garden where Leeks did grow, wearing Leeks in their Monmouth caps, which your majesty knows to this hour is an honourable padge of the service; and I do believe takes no scorn to wear the Leek upon Saint Tavy's Day.
Ibid., act iv., sc. 7.
- (4) In act v., sc. 1, is the encounter between *Fluellen* and *Pistol*, when he makes the bully eat the Leek; this causes such frequent mention of the Leek that it would be necessary to extract the whole scene, which, therefore, I will simply refer to in this way.

We can scarcely understand the very high value that was placed on Leeks in olden times. By the Egyptians the plant was almost considered sacred, "Porum et capre nefas violare et frangere morsu"—(Juvenal); we know how Leeks were relished in Egypt by the Israelites; and among the Greeks they "appear to have constituted so important a part in ancient gardens, that the term *πρασά*, or a bed, derived its name from *πρασον*, the Greek word for Onion," or Leek—(Danbenny); while among the Anglo-Saxons it was very much the same. The name is pure Anglo-Saxon, and originally meant any vegetable; then it was restricted to any bulbous vegetable, before it was finally further restricted to our Leek; and "its importance was considered so much above that of any other vegetable, that *leac-tun*, the Leek-garden, became the common name of the kitchen garden, and *leac-ward*, the Leek-keeper, was used to designate the gardener."—(Wright). The plant in those days gave its name to the Broad Leek which is our present Leek, the Yne Leek, or Onion, the Garleek (Garlic), and others of the same tribe, while it was applied to other plants of very different families, as the Hollow Leek (*Corydalis cava*), and the House Leek (*Sempervivum tectorum*). Its popularity still continues among the Welsh, by whom it is still, I believe very largely cultivated; but it does not seem to have been much valued in England in Shakespeare's time, for Gerarde has but little to say of its virtues, but much of its "hurts." "It heateth the body, ingendreth naughty blood, causeth troublesome and terrible dreames, offendeth the eyes, dulleth the sight, &c." Nor does Parkinson give a much more favourable account. "Our dainty eye now refuseth them wholly, in all sorts except the poorest; they are used with us sometimes in Lent to make pottage, and is a great and generall feeding in Wales with the vulgar gentlemen."

Lemon.

Biron. A Lemon.
Longville. Stuck with Cloves.
Love's Labour's Lost, act v., sc. 2. (See Orange).

Lettuce.

Iago. If we will plant Nettles or sow Lettuce.
Othello, act i., sc. 3. (See Hyssop).

This excellent vegetable with its Latin name, probably came to us from the Romans. It was cultivated by the Anglo-Saxons, and in Shakespeare's time the sorts cultivated were very similar to, and probably as good as, ours.

H. N. ELLACOMBE.

(To be continued).

Insect Friends.—I find the insect herewith sent to be very troublesome. What is its name?—J. J. [The name is *Omasus melanarius*, but it is a friend, not an enemy. It is carnivorous, and feeds on other insects.—A. M.]

Variiegated New Zealand Flax in Flower.—We have a fine specimen of the *Phormium tenax variegatum* now in flower; the flower-stalk measures about 9 ft. Is it not an uncommon thing for this Flax to flower in this country?—J. C. BARBOE & SON, *Borrowash, Derby*.

IVY SCREENS.

WE have spoken at various times in THE GARDEN of the charming and varied uses to which the common Irish Ivy is put in gardens in the neighbourhood of Paris. This spring we had a photograph taken of an Ivy-covered railing on the Boulevard de la Seine, near Conrbevoie, from which the accompanying illustration has been drawn and engraved. It is simply one of many which may be seen in and around Paris; there, where the winter is very severe, as many know to their cost, and where as many evergreens do not grow as with us, it is refreshing to see the many Ivy-clad surfaces in winter and spring, when most of the trees and shrubs are bare. On the railings the Ivy, while furnishing a pleasing effect to the eye (far more so than bare railings), is also often useful as a screen. Young and vigorous plants, uniform in size, set in rich, light earth, soon cover these railings, as shown in our illustration. The Ivy is so trained that the beautiful shield-like leaves form a uniform imbricated wall of verdure.

PLANTING VASES AND FLOWER BOXES.

IN many villa gardens, vases, where tastefully planted, form quite an attractive feature. The most suitable positions for them are the sides of flights of steps, at each side of a doorway, on terrace walks, or along a balustrade; they should not be placed too near windows, nor should they be anywhere crowded. Various materials are employed in the manufacture of vases, such as stone, iron, and plaster, but the best are made of terra-cotta. Vases are of various sizes and shapes, some being broad and shallow, others deep and narrow. The shape of the vase will invariably determine the style of planting. A flat vase should be planted with rather dwarf plants, with trailers hanging over the rim. Deep and narrow vases, on the contrary, should be furnished with tall plants. It would be

out of character to plant a Tulip-shaped or Oriental vase with very dwarf plants; they require to be furnished with something tall and having drooping branches, as, for instance, a Fuchsia, or *Humea elegans*. As a rule, vases do not receive that attention which they deserve. They are frequently left until the last, and filled with odds and ends after the beds in the flower garden have been planted. Vases, before being planted, should be well drained, and the best soil for them is fresh turfy loam and rotten manure, to which should be added a little leaf-mould. For furnishing large vases, where tall plants are required, I take up a quantity of Pelargoniums in autumn, and keep them in small pots or boxes through the winter, for I find that those struck from cuttings in autumn are not so good for the purpose. For deep vases, rising about 3 ft. from the ground, and standing at the end of a terrace walk, nothing is more suitable than the *Humea elegans*, surrounded by trailing plants hanging over the sides. Most of the plants used for flower-garden decoration will be found suitable for vases. Pelargoniums will invariably form the staple, but to these may be added *Calceolarias*, *Lobelias*, Dwarf Fuchsias, *Centaurea gymnocarpa*, *Mesembryanthe-*

mums, Ivy-leaved Pelargoniums, various *Tropæolums*, *Humea elegans*, and *Heliotropes*; other plants might be used, but these, well arranged, will produce a good effect. In planting a broad flat vase begin at the rim with plants that will hang over the edge, such as *Lobelias*, Ivy-leaved Pelargoniums, and *Tropæolums*; let the next circle consist of somewhat taller plants, such as variegated Pelargoniums, and finish off with the tallest in the centre. When *Tropæolums* or Ivy-leaved Pelargoniums are used for draping the sides, it is a good plan to run one or two pieces of copper-wire round the outside of the vase, to which to tie the plants, in order that they may not be chafed by the wind. The *Petunia* is a useful plant for vases, inasmuch as it flowers more profusely when pinched for root-room than when unrestricted in that respect; but it requires plenty of water—watering, indeed, will demand careful attention throughout the summer, and when the plants have made good root-growth, liquid manure may be given twice a week. When the beauty of the summer-flowering plants is over, hardy plants and bulbs that will bloom and look gay in spring should occupy their places. Among the former may be mentioned Wallflowers, *Saxifraga cordifolia*, and *S. crassifolia*, and others, which, if margined with *Aubrietia deltoidea*,

will produce a charming effect that will be greatly enhanced by the addition of a few Tulips and Hyacinths. Besides hardy perennials, we have quite a wealth of dwarf shrubs at our command, such as *Rhododendrons*, Heaths, *Aucubas*, and Box, with Ivies for trailing round the sides. As regards boxes, in western London it has become fashionable for every window to be a miniature flower garden, on which considerable sums are annually spent, and notwithstanding the smoke and dust in summer, they look remarkably gay. For window boxes like vases we have a large variety of suitable plants, among which may be named Stocks, Asters, Pelargoniums, both plain-leaved and variegated, Fuchsias, *Mignonette*,

and Musk, and to these may be added *Lobelia*, Ivy-leaved Pelargoniums, and *Mesembryanthemum cordifolium variegatum*, to hang over the sides. A few *Tropæolums* of the *Lobbianum* section, Canary Creepers, and *Convolvulus major*, might likewise be trained up the sides and over the top of the window, so as to form an arch.

K. R.

Railing Screen of Irish Ivy.

Wistarias as Wall-top Climbers.—Few prettier objects can be found than a Wall well furnished with fruit trees, and overhung with the lovely pendulous blooms of the *Wistaria*. We have a plant of it here that in a few years has run along the coping 50 yards each way, and it still continues to extend its growth many feet annually. As a rule I dislike combining fruit and flower culture, but this light feathery-leaved climber repays so well the slight amount of attention which it requires, and is moreover rather beneficial than otherwise in the way of protecting the fruit crops, that an exception is made in its favour. It is of course spurred in so that the side branches just hang over the edge of the wall coping, the leading shoots being left to extend themselves at will. It apparently enjoys an immunity from insect plagues, a great advantage when grown in connection with fruit trees.—JAMES GROOM, *Henham*.

OPEN-AIR VEGETATION IN APRIL.*

THE weather during April upon the whole has been cold, and much against open-air vegetation, perhaps more so than has been observed on the 30th of April for many years, the wind nearly the whole month having an easterly tendency, except on the 20th, when it got round to the south-west, which brought forward the flowers of the Norway Maple and certain Elms, also the young leaves of some of the Hawthorns, besides greatly increasing the size of the leaf-buds of certain Planes and Horse Chestnuts, but without expanding them. After that day the wind veered round to the east again, and vegetation has progressed very slowly, so much so that forest vegetation, with the exception of the few examples quoted, has quite a wintery appearance. Herbaceous vegetation is also very far behind, the diminutive condition of many plants being very marked. Some of the ordinary early-blooming plants have been also late in flowering. The Crown Imperial (*Fritillaria imperialis*), which is often past by this time, is scarcely yet in perfection. Many Scillas and other spring bulbs, which usually flower in March, are now in good bloom, and even the common Crocus can still be found in flower; Snowdrops were also procurable about eight days ago. Standard plants of the *Ribes sanguineum* have not been particularly good this season, their flowers being still much behind. Many other examples might be quoted, the foregoing, however, is sufficient to show the backwardness of vegetation. In my report for March, I stated that certain species of *Cypripedium* had suffered severely; the browning complained of is still going on, and many of the plants then noticed are permanently disfigured. During the month of April the thermometer has been ten times at or below the freezing point, indicating collectively 50°, the six lowest temperatures were on the 2nd, 11th, 12th, 14th, 20th, and 25th, when 26°, 26°, 23°, 24th, 23°, and 27° were respectively registered, while the six highest night temperatures were on the 8th, 9th, 15th, 16th, 21st, and 22nd, indicating respectively 39°, 40°, 40°, 30°, 42°, and 38°. The prevalence of low night temperatures of late has been remarkable, nor can it be otherwise while so much snow lies in various parts of the country. Throughout April the six highest night temperatures, as already noted, only amounted to 23°, being lower than had been noticed during the corresponding month last year, when the six highest indicated collectively 290°, all counted above zero, or 47° above the freezing point for April, 1877, and 101° for April, 1876. On April 30, ninety-seven species and varieties of plants were counted in flower on the rock garden, while the corresponding day last year 122 were noticed, the most conspicuous at the present time being—

<i>Adonis vernalis</i>	<i>Primula ciliata purpurata</i>
<i>Anemone nemorosa bracteata alba</i>	<i>Primula denticulata</i>
<i>Anemone Robinsoniana</i>	<i>Primula helvetica</i>
<i>Aubrietia grandiflora</i>	<i>Primula integrifolia</i>
<i>Colechicum sibiricum</i>	<i>Primula nivalis</i>
<i>Dondia Epipactis</i>	<i>Primula purpurea</i>
<i>Draba aizoides</i>	<i>Primula vulgaris</i>
<i>Erica hybernica alba</i>	<i>Pulsatilla bracteata</i>
<i>Erica hybernica intermedia</i>	<i>Puschkima scilloides</i>
<i>Erica hybernica nana</i>	<i>Saxifraga cordifolia</i>
<i>Erythronium grandiflorum</i>	<i>Saxifraga retusa bryoides</i>
<i>Erythronium giganteum</i>	<i>Scilla sibirica</i>
<i>Erythronium giganteum roseum</i>	<i>Scilla praecox</i>
<i>Fritillaria aurea</i>	<i>Soldanella montana</i>
<i>Orobanchia elegans</i>	<i>Trillium grandiflorum</i>
<i>Polygala Chamæbuxus</i>	<i>Tulipa pulchella</i>

The following spring plants complete the list annually recorded to show their period of flowering:—

	1877.	1876.
<i>Symphytum caucasicum</i>	April 5	March 15
<i>Narcissus Pseudo-Narcissus</i>	" 8	April 3
<i>Adonis vernalis</i>	" 12	" 5
<i>Fritillaria imperialis</i>	" 14	" 6
<i>Hyoseycaus physaloides</i>	" 16	" 2

In my monthly returns on open-air vegetation it is not usual to give any remarks on the vegetation of the current month, but as this May, so far as it has gone, has been rather an exceptional one, I cannot refrain making a few observations in order to show the amount of cold we have had up to this time. Frost has been seen more or less every morning, with two exceptions, varying from 1° to 8°, making collectively (up to this date, May 10) 30°, the exceptions being on the 9th, when the thermometer stood at 33°, and on the 10th at 37°. The frosts experienced during May for the last twenty-three years are given in a Table on page 523 of Vol. xii. of the "Botanical Society's Transactions" for 1876-77. In May, 1855, 29° were registered; in 1861, 21°; in 1869, 13°; in 1874, 16°; and in 1876, 26°. From this Table it will be seen that during four years no May frosts were noticed, during five years 1° only each year was

* Read by Mr. J. MacNab before the Botanical Society of Edinburgh, May 10, 1877.

recorded, and for twelve years from 2° to 6° were registered. It is difficult at the present time to say with exact certainty the period vegetation is behind former years, probably not less than three weeks. For twenty-eight consecutive seasons we have had the young branches of the Beech each 5 in. long to hand to the students attending the botanical class either on the 8th, 9th, or 10th of May, to show an example of an alternate leaf. This year no shoot is yet out of its winter scales. Many other examples of open-air trees (to show venation and prefoliation) daily occur; all are, however, behind, while other plants are now in good condition, such as the *Fritillaria imperialis*, which is generally past at this period of the year. In consequence of the length of time leaf-buds have been pent up caused by the long, ungenial spring, it is but reasonable to expect that as soon as a favourable change takes place, and with the present moisture in the ground, we shall observe a rapidity in the development of foliage such as is seldom seen.

Malope grandiflora.—This, one of the most showy of hardy annuals, well deserves a place in every garden where a bold, showy crimson flower is desired. It to from a height of from 18 in. to 20 in., and the better the plants are treated in regard to soil the finer will they bloom. If I wanted some extra good examples of it I should sow half-a-dozen seeds in a 3-in. pot in some thoroughly good soil, raise them in a greenhouse, and, when large enough and sufficiently hardened off, place the contents of the pot in the border without breaking the ball of soil. Treated generously in this way the plants become strong, and the flowers large and brilliant in colour. As a rule annuals are regarded as scarcely deserving much trouble; they are sown in haphazard ways, and are often left to take care of themselves in uncongenial soils. If the *Malope* be sown in the open ground, it is only fair that it be prepared by digging and manuring it, and then the seeds should be sown in some light, rich soil $\frac{1}{2}$ in. below the surface, and gently pressed down. The soil that is added soon starts the young plants into good growth, when they strike their roots down into the material prepared for their reception. Too often annuals only root superficially, and then when hot, dry weather sets in they soon go out of bloom. There is a white variety named *M. g. alba*, which is the counterpart of *M. grandiflora*, with the exception of the colour. The new variety called *M. g. rosea*, white flushed with rose, is also very pretty, and quite distinct; at Chiswick last summer this new variety was remarkably effective. When I was in the neighbourhood of Dublin in 1869, I saw in a private garden a striped sport from *Malope grandiflora*, the ground colour of which was white streaked with rosy crimson. It was very beautiful, but it went the way of many other sports; it reverted to the parental form, from which it never again varied. I am informed that it sometimes takes from eight to ten years to get a sport to become fixed; it has to be rigidly selected year by year before its character is established.—D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Greig's Tulip.—I was pleased to see a figure of this in THE GARDEN, though it is difficult to give an idea of its bold beauty and splendid colour. I have long grown Tulips, and never expected to see among new species anything that for brilliancy equalled the old and popular varieties, but this surpasses them, and is, I think, the finest of all early Tulips when well established in good soil.—H. J.

Squills in Bloom at Fulham.—In our collection of Squills the following are coming beautifully into flower, viz.:—*Scilla campanulata*, *S. c. alba*, *S. c. carnea*, *S. patula*, *S. nutans alba*, and *S. n. carnea*. *Muscari comosum*, *M. monstrosum*, and *M. racemosum* are also coming finely into bloom.—R. O.

Osborn's Golden Feverfew (*Pyrethrum aureum laciniatum*).—This is an elegantly-cut-leaved form of the well-known Golden Feather *Pyrethrum*, and is so compact and distinct in habit, forming masses of soft, golden leafage, that it well merits culture for edgings, or as a carpeting plant. Like its ally, it comes true from seed.—B.

—This is acknowledged by every one to be a decided improvement on the common Golden Feather, the leaves being beautifully fringed or serrated, and it is even dwarfer and more spreading in habit than the old variety. It is very hardy, and is one of those plants that, let the season be what it may, is always in good condition. It should be raised from seed sown in March in boxes of light soil in gentle heat, and pricked out into frames, so as to form good plants by the middle of May.—J. Groom, *Hendon*.

Aubrietia grandiflora on Rockwork.—While passing along Kilgraston Road on the south side of Edinburgh a few days ago, I was quite charmed to see the garden ground in front of Mr. Moxon's residence arranged as an irregular rockery, and completely covered with the rich mauve-coloured flowers of this *Aubrietia*. These flowery banks vary from 10 ft. to 12 ft. long, and about 5 ft. or 6 ft. broad, and the irregularities are of various heights from 2 ft. to 4 ft., all covered, as it were, with light-blue cloth. The garden has a westerly aspect, and, notwithstanding the present ungenial weather, such a show of bloom produced at this season is well worthy of imitation.—JAMES MACNAB, *Royal Botanic Garden, Edinburgh*.

THE KITCHEN GARDEN.

TYING EARLY CABBAGES.

DURING the past few weeks we have noted growers for market very busily engaged in tying up their early Cabbages in the market gardens at Fulham and elsewhere. The operation is simple, just, in fact, that adopted in the case of Cos Lettuces. The succulent outer leaves are folded carefully around the heart or centre of the plant, and the whole is bound firmly with a withe or piece of bast, as shown in the annexed sketch. There are several good reasons for this practice. The centre being protected from the weather, the Cabbages heart sooner

Early Cabbages tied and untied.

by two or three weeks than they otherwise would do, and they are more easily handled in gathering and packing for market. This plan is seldom adopted in private gardens, but there can be no doubt that it is one that can be recommended, inasmuch as there is a gain of a week or two as regards cutting, and compact little Cabbages are always preferable to loose ones, which moreover are apt to get broken and otherwise injured in gathering. B.

A MIXED FRUIT AND VEGETABLE GARDEN.

IN the neighbourhood of Fulham where land is chiefly devoted to market garden crops the most has to be made of it, owing to the high rental which it realises. For a plot of several acres

Plan of Undercropping Orchards.—*a*, Victoria Plum Trees. *b*, Marie Louise Pear Trees. *c*, Gorseberries and Black Currants. *d*, Rhubarb. *e*, Daffodils and Poet's Narcissus. *f*, Wallflower. *g*, Asparagus and Seakale Beds.

just behind the Peterborough Arms, Walham Green, £12 per acre is paid, and there are fruit gardens in sheltered localities of which the rental is even greater. The annexed sketch represents the cropping of the £12 per acre plot, which consists of fruit trees undercropped with vegetables and flowers, a plan which is said to be highly remunerative. The produce of fruit alone one year with another realises £25 per acre. As shown in the woodcut the Plum and Pear trees are planted alternately in the rows, a plan by which the taller-growing

Pears throw very little, if any, shade on the Plums. Gooseberries and Currants do well under standard fruit trees, if the latter be not planted too thickly. Not a little of the success which attends the undercropping of vegetables, hush fruits, and flowers, however, is due to the large quantities of rich, well-rotted manure and manure-water that is obtained from a clean and well-managed piggery, the occupants of which consume the superfluous vegetables and fruit. B.

POTATO PLANTING.

It is said (see p. 360) that "the old practice of spreading the manure in the row and planting the sets upon it is still commonly practised. In planting field crops hardly any other plan can be conveniently adopted." With this practice I disagree. I grow Potatoes in a field, of about 3½ acres as follows:—The land intended for them is selected early in winter, and before Christmas it is roughly and deeply tilled. About the end of January manure is spread over it at the rate of about 25 tons to the acre, and then buried. A week or ten days before planting the ground is well worked with the cultivator, which not only loosens it, but thoroughly mixes the manure through it. Before planting the drills are drawn about 30 in. apart, and all is ready for the sets. Under all circumstances, when the ground is not occupied with other crops, it should be turned up before Christmas; and when the soil is of a retentive character, the manure should be added at the same time. If the soil be open and porous, then the manure may be worked in equally all through it six or seven weeks before planting. It is a mistake to place the sets on raw stable manure in the trenches; indeed, it must have been observed that when the Potatoes are dug up the manure is reproduced in a state of dry flakes that would require a large quantity of water to moisten them; it cannot therefore be said to have helped to produce the Potatoes which it was designed to do. I know that many cottagers who have a poor soil often put little manure into the trenches, with the view of making the most of it, but as the plants advance in growth, and the roots keep spreading and striking out in search of fresh food, they escape into a barren soil, and just when the crop requires extra support the roots are unable to furnish it. Ten tons of manure to an acre, well worked through the soil, 18 in. or 20 in. deep, if the subsoil be pretty good, would be likely to produce one-fourth larger crop of good Potatoes than 20 tons put into the trenches immediately under the sets. The start which the plants would receive at first when the sets were placed on the manure would merely produce foliage, to be starved afterwards from want of food. I dig the ground for our garden crops two spits deep, applying the manure about six or eight weeks before the ground is required for planting. In all cases the time of planting must be regulated by locality, position, and season. In warm, sheltered situations, planting may be done early in March, but in low-lying, confined valleys, it is better deferred until towards the end of April. I plant early crops 3 ft. apart, but I intercrop with Brussels Sprouts. Much of the success of the Potato crop depends on the choice of sets. I have a great aversion to cutting Potatoes into many sets, and it is a mistake to select either very large or very small sets. In all cases moderate-sized and the best-shaped Potatoes should be chosen for the purposes of planting. I have tried the experiment of removing every eye except the one nearest the crown of the tuber; this I found prevented the production of useless haulm. These sets, with only one shoot left, produced a fine, healthy crop of even-sized tubers, while those not disbudded and planted with all the sprouts undisturbed, produced the largest quantity of very small Potatoes. Of early Potatoes for garden purposes, we have nothing better than Mona's Pride. The old Ashleaf is, however, still good, and Rivers' Royal Ashleaf is also a general favourite. To succeed the above, Lapstone Kidney stands unrivalled where the land suits it. For field cultivation we find none better in quality than the true York Regent, Paterson's Victoria, and Skerry Blue. The York Regent must not be confounded with the Scotch Regent. For the last ten years Flnkes with me have degenerated, and the crop, notwithstanding that we have sent to Scotland for the seed, has been less and less every year. P. V.

Lettuces Under Glass.—There is such a marked superiority in produce of all kinds grown quickly under glass compared with that out-of-doors, especially if aided by the least bit of bottom-heat, that one wonders how any one with the means to make or buy a few movable frames or lights can wait quietly for their early crops to come in naturally during such a wretched spring as this has been up to the present time. I have been led to make these remarks from looking at a frame full of early Paris market Lettuces that were sown in a box in January in heat close to the glass. About the end

of February an old-fashioned deep frame was filled within 6 in. of the top with hot manure, and made firm by treading, 4 in. or 5 in. in depth of light, rich soil were placed all over the surface, and the Lettuces pricked out 6 in. apart. On cold nights a straw mat was thrown over them, but otherwise the labour and trouble expended in the matter have been almost nothing. It has often been stated that the French cultivator excels his English *confrère* in the production of early Lettuces; and the produce imported into Covent Garden doubtless bears this out, but this superiority is mainly due to the use which the Frenchman makes of his cloches, and there is no question that if the means placed at our disposal were increased, the cost would soon be repaid in the improvement that would take place in the quantity and quality of the produce. I do not care much what shape such protectors assume, whether cloche or frame, the main requirements are shelter and light, and if these be secured the lightest and cheapest covers are the best.—E. HOBDAV.

When to Plant Early Potatoes.—It is sheer waste of time to plant early Potatoes before the 25th of April; even then, when

endorse all that "A. D." says (see p. 386), for having always planted early, I have five seasons out of six had to smart for my folly. Here (North Hants) on the morning of the 5th inst., the thermometer registered 23°, or 9° of frost, which not only destroyed the Potato haulm in its entirety, but Peas that were in flower had their blossoms destroyed; Asparagus was blackened and worthless; Apples, Pears, Plums, and Cherry blossoms were so injured that instead of there being a heavy crop of fruit, as indicated a few weeks ago, it will be the most meagre that we have had for many years past.—W. W. H.

Early Potatoes in Pots.—Being short of frame room in which to force early Potatoes, I have this season grown a quantity in 10-in. pots, and placed them in Vineries and Peach-houses, moving them from place to place as occasion demanded. The pots were half-filled with light loam, with which was incorporated a tenth part of fresh horse manure. Three sets were placed in each pot, and when growth had fairly begun, they were earthed up with similar soil to within 1 in. of the rim of the pot. The first batch was planted the first week in January, and the first Potatoes lifted on April 4, each pot

The old idea: Geometry—stonework—formality.

peeping above ground, they should, in order to make them safe, be earthed over. Previous to planting, my early Potatoes are all laid thinly on shelves in cool sheds, where the sprouts become thick and sturdy, and from 2 in. to 3 in. in length; the land being all dug and manured in autumn and laid up roughly, it is broken up in spring with a three-tined draw hoe-fork. The drills are made 3-in. deep, and the soil is drawn over them so as to form miniature ridges. There is no occasion for early Potatoes being cut down by frost if at once be paid to earthing them up. I may add, however, that I lose half my crop under field culture yearly, by disease but this season I hope to have all lifted by the end of August at the latest—the early ones by the first week in August. Mr. E. Luckhurst, of Oldlands, has, during six years running, saved his crop by doing this, and I see no reason why anybody else cannot do the same.—R. GILBERT, *Burghley*.

— Hereafter I do not intend to plant any Potatoes till well into the month of April, and after the experience of the present season, may, I imagine, will be inclined to follow my example. I can quite

producing from eighteen to twenty-four good tubers, thus giving us a fine dish of Potatoes with but little labour or inconvenience. The kinds grown were Veitch's Ashleaf Kidney, and Fenn's Early Market, a round variety; the haulm of the latter is so short, and the sort is so wonderfully prolific, and of such good quality, that it must eventually become our best early Potato.—W. H.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Paraffin-oiled Seeds v. Vermin.—"A Northern Gardener's" experience of this remedy (see p. 34) is exactly similar to my own. I steeped a quantity of Peas in this oil and sowed a portion of them, leaving the remainder in a shed thinking that they would be safe, but the rats ate them all but the husks; and, as they were under cover, they could not have lost the nauseous effects of the oil, as the tin which contained them was saturated with it. There is one benefit that I believe seeds do derive from such dressing, viz., that when sown, rats or mice do not find them so readily as they otherwise would do, as the powerful smell of the paraffin counteracts that of the seeds.—J. GROOM, *Henham*.

TWO VIEWS IN GARDENS.

HERE we have a beautiful free view in a park, with a breezy open foreground, a bit of well-formed artificial water, and a peep at a distant wood and village, with naturally-developed trees, and perfectly free from any of the puerilities with which large gardens are so often disfigured. On the preceding page is a view in one of these wonderful places, frequently called monuments to the genius of somebody, whose often enormously expensive work only resulted in making the earth much less beautiful than it was before he touched it. It is one of the costly follies at Caserta. It was a favourite doctrine with the creators of these gardens that nothing near the house was to assume a natural form. The noble and long-endured doctrine was that everything near the house was to be trimmed into uniformity to associate with architecture and stone work. Even to the present day this harmful stuff is printed in books on landscape gardening, and unfortunately

THE FRUIT GARDEN.

STRAWBERRY CULTURE IN POTS AND BEDS.

THE time of year having again come round in which to start with the formation of new beds of the above, and the preparation of plants for forcing, a few remarks relating thereto may not be without some use or interest to a portion of the readers of THE GARDEN, although I shall not be able to announce any new discovery or point out a road to success without a considerable amount of attention and time being spent to secure that much-desired result. As regards the pot-culture of this highly esteemed fruit, the first and most important thing is to obtain strong early runners, for without these it is impossible to grow plants with large, fully-developed crowns, without which the crop they yield will be anything but satisfactory. Where Strawberries are forced early, and are therefore

Park Scene, showing Village and Wood in the distance.

often illustrated in earth, and stones, and trees. The formal walls of trees in the distance in the Caserta view show how very far into the grounds this tree shaving was carried. We ought, perhaps to be grateful that the Le Notre of the scene did not square the head of the hills which have so long smiled down on all this costly confectionery. In those days money seems never to have been wanting for the formation of colossal absurdities.

Clay Soil for Pears.—I have found that the stiffest, hardest yellow clay is the best soil in which to plant a Pear tree, and a sandy soil the poorest; and the same recommendation is applicable to the Plum. I can show trees growing in a hard, stiff clay that would be very hard to beat for thrift and vigour of roots, wood, leaves, bark, fruit—in fact, for anything pertaining to a Pear tree. Of course I do not assert that good trees cannot be grown on a sandy soil, but I must believe such growth and adaptation very exceptional indeed, and should always select a strong yellow clay for Pears and Plums, where possible. Nor would I seek to fertilize such soil too strongly; most of clay meadow land, properly drained and well tilled, will grow Pears to perfection.—H. HENBRICKS, in "Cultivator" and "Country Gentleman."

available for planting out, it is a very easy matter to obtain these early runners, as when once they begin to make fresh roots in the open ground, they emit them in the greatest profusion, and having no crop to carry, as other established plants usually have, the runners they form are invariably much more robust than any that are produced in the ordinary way. This being the case, those who would be well prepared for next year should commence turning out any from which the fruit has been gathered, as every day lost now is so much less time for them to grow and mature their crowns. In doing this, choice should be made of a convenient situation for the pots, and one that is readily accessible for giving them water, of which there must be no stint, or their progress will be at once checked, and the leaves subject to the attacks of red spider, a pest that assails them both indoors and out if they be neglected in any way. The practice with us is to open a trench about half a spade deep, near the margin of any of the walks bounding or intersecting the kitchen garden, and in the bottom of this to work in a good coat of decomposed manure much after the

manner adopted in preparing for Celery, and in the trench so formed the plants are placed at about 12 in. or 15 in. apart, and the soil filled in firmly around them, which keeps the crowns below the general level, and obviates the difficulty of giving them the requisite supplies of water to induce a free formation of runners, and to support them till they become well established in the pots in which they are layered. The advantage of having them planted near the margins of walks is twofold; for, independent of the facility with which they may be watered, a firm, hard bottom is secured to the pots, which is a very important matter, taking into consideration the trouble and annoyance worms cause by blocking the drainage, and the injurious results that follow therefrom. Soot acts as a great deterrent to their ingress, and, as it is likewise an excellent fertiliser, a small handful should be scattered over the crocks before filling the pots with soil, the latter of which ought to be in a moderately dry state so as to admit of being rammed or pressed in firmly, a condition that checks that undue tendency of leaf growth to which all Strawberries are more or less liable when their roots can rumble at will. Turfy loam that has been laid up for a year for the herbage and fibre to become decomposed is the best soil in which to grow them, but if this be naturally of a light character it may be greatly improved by the addition of clay or marl, either one or the other of which may be obtained in most places. In order to get it to mix regularly with the loam the clods should be exposed to the sun and air or laid in sheds to dry, when it will be found to crack and fall to pieces, and may then be beaten up by a light rammer or the back of a spade almost as fine as dust, in which state there will be no difficulty in getting it incorporated with the loam to give the requisite consistency. The quantity used must depend on the nature of the soil to be treated, but in no case should it exceed one-sixth, otherwise the tendency is, from the repeated waterings it has to undergo while the plants are growing and fruiting, to become close and sour, or when a little dry to bind so closely together as to crack and shrink from the sides of the pots. Although no advocate for mixing manure with soils for potting in a general way, the limited amount of root-room Strawberries have when so confined renders such a course in their case necessary, but what is applied should be of a mild form, and that has been laid by for a long time in some dry place to sweeten. Such as is obtained from cows, deer, or sheep, is by far the best for the purpose, a store of either one or the other of which should be kept ready to hand in all gardens for uses of this kind, and for top-dressing Pelargoniums and other soft-wooded plants.

Size of Pots and Layering.

Much diversity of opinion exists as to the size of pots most suitable for the growth of Strawberries and the number of plants each should contain; but from long experience, and having tried both small and large, I am decidedly in favour of the size known as thirty-twos or 6-in., as I have always found them thrive better in those than in any others, especially for late work; for very early forcing, however, and for such moderate-growing kinds as Black Prince, Keen's Seedling, and Vicomtesse Héricart de Thury, 4½-in. pots may be used, and if these be plunged in leaf-soil in others a size larger to screen them from the sun and prevent too rapid drying of the roots, very fine fruit may be obtained, and of a superior flavour to that from plants requiring a more frequent use of the watering-pot. In layering the best plan is to put the runners at once into the pots it is intended for them to remain in, as that saves further time and labour in shifting them on, besides which, their growth is much faster on account of the assistance they derive from the old plants, as these continue to feed them as long as they are attached. On several occasions I have tried them in both ways—that of layering them as above, and in the ordinary manner in 3-in. pots, and the result has been in each case considerably in favour of the former, which is not to be wondered at, seeing that they receive no check from first to last, but go on steadily growing till they ripen in the autumn. For securing them firmly to their proper position in the pots at the time of layering, there is nothing more suitable than small-sized pebbles laid close to the base of the runners, as they shade the soil in that particular part, and from the way they intercept and attract moisture beneath them, main-

tain a more uniform state, highly congenial to the formation of roots. Where these cannot be readily obtained, short, stiff pegs made from old Birch brooms may be substituted; and in placing the layer a slight indentation should be made in the soil to admit of the runner being covered slightly before or after pegging it down. This done, they must be well attended to with water, but care must be exercised that this is never used in excess, particularly for the first month or so after layering, as it should be borne in mind that the plants during that time have but few roots to absorb it, and what is therefore needed is a uniform degree of moisture to encourage their formation as quickly as possible. As growth proceeds and they begin to fill their pots, weak liquid manure given two or three times a week will be of the greatest assistance; and this aid should be afforded them till the end of September, after which all they will require is sufficient water to keep them from flagging till stored away for the winter. Where cold frames and any old lights to ward off wet and frost can be spared, choice should be made of them for shelter, in preference to packing the pots in leaves or ashes on their sides, as in the latter position the dry, searching winds have such an effect on the crowns of the plants as to cause them to shrivel, and it often occurs that the roots are not in a much better condition. In pits or frames plunged near the glass in a bed of half-decomposed leaves, they are as snug as it is possible to have them, and from their being so circumstanced they respond readily when heat is applied after the turn of the year. To obtain ripe fruit in March, which is as early as is practicable in most places, the plants should be started the first week in January, and the best situation for them for the first month or so is a pit having a hot-water pipe along the front and a bed of gently fermenting leaves in which to plunge the pots, so as to induce an active state of the roots and assist them in pushing up strong heads of bloom. Any light, airy shelf in a Peach-house or Vinery at work will do almost equally well, but wherever placed, the forcing during the early stages must be slow, as Strawberries are impatient of much heat, an excess of which before they are fairly set is sure to cause failure. Want of air will likewise produce the same results, indeed it is even more fatal than a high temperature, especially while the plants are in bloom, as there is no chance of the pollen ripening and becoming distributed in a close, moist atmosphere; and unless this takes place, it is impossible for the flowers to become properly fertilised or for the fruit to swell, except in the most irregular manner. Light, air, and sun are the three essentials in early Strawberry forcing from the beginning to the end of the crop, and therefore the plants should be ranged as close to the glass as can be done without their foliage actually touching it, and in such a position as to be near the ventilators where the atmosphere is kept in continual motion. So situated, and with plenty of water, the fruits will finish off with that rich, glossy, varnished appearance, that is a sure index of good flavour. In order to get them of large size they should be thinned out as soon as set, in doing which those only on the main stems should be left, as they always swell off the best, and are the handsomest when ripe. During the time they are swelling, clear liquid manure should be freely given till they begin to colour, but not after, as it imparts an unpleasant taste to the fruit. To support the weight of fruit while hanging on the plants, a piece of small twine strained tightly along the front of the row is a much quicker and more satisfactory way than applying a stick or bushy twig to each pot, and it will last during the whole of the season. To prevent it drooping in the middle when it becomes a little slack, a tack driven in the rafter or sash bar every 3 ft. or 4 ft., with a piece of twine run from each and attached to that strained as a rest for the fruit, will keep it in its proper position.

Culture in Beds.

In forming fresh beds, the most important thing is to trench the ground thoroughly, and next to this to manure heavily with short, cool manure, such as that from the cow or pig yard, and this done, it must be poor soil indeed that will not produce good Strawberries. Trenching, however, as generally carried on by bringing the subsoil to the surface, is a great mistake, as it takes years to get it in a fit state for the roots of plants to feed on, and from its inert condition, through the

absence of vegetable matter, it binds so closely as to be almost impervious to atmospheric influences. It follows, therefore, that in breaking up the land, much of the bottom should not be brought to the surface at any one time, but the manure should be kept well down, for the double purpose of gradually enriching it, and as a storage of food for the roots during a long continuance of dry weather. Although Strawberries require a deep, rich soil, it should by no means be loose and hollow, but made as firm and compact after the trenching as possible, or the produce will be little else than leaves. In gardens, where there are forced plants now turned out, or such can be had, they are much preferable for making fresh beds to runners, as being already well established with large balls, the plants go to work at once, and bear enormous crops the season after planting. So satisfied am I with these that I never use any other, except it may be the runners of a new variety or any kind I do not force, and I always find the pot plants make the best beds, and are more satisfactory in every way. The practice here is to make a fresh plantation every season, and to destroy one of like extent, so that none stand longer than two years, as after that they do not produce fruit of sufficient size to make it worth while keeping them. The system with many is to take runners at random any time in August or September, and to dibble them into any spare ground from which a crop has been cleared, with little or no preparation beyond raking it over or just digging it up, but under such unfavourable conditions the yield is never satisfactory. In planting out the forced plants, the ball should not be disturbed, but dropped whole in the ground, and the soil made firm, leaving it in a basin-like form to hold water to be given occasionally till the plants can take care of themselves. So treated, they will bear a fair crop in the autumn after others are done, a time when they are sure to be doubly appreciated. The best to grow for outdoor work are Vicomtesse Héricart de Thury, President, Sir Charles Napier, Sir J. Paxton, British Queen, and Elton Pines, all of which ripen in the order they are placed. As most of these are strong growers, they should not be planted nearer than $2\frac{1}{2}$ ft. row from row, and 18 in. or 20 in. from plant to plant, that sun and air may be freely admitted amongst them to colour and finish off the fruit. Directly this is gathered, all runners and shabby, superfluous foliage should be cleared away, and the beds hoed over to free them from weeds and loosen the surface, that any rain that falls may be able to penetrate freely. As a winter protection, a mulching of rotten manure is the most effectual, but under no consideration should the ground be dug over or disturbed in any way beyond a slight hoeing, as in so doing the surface and most important roots would be destroyed.

Protecting the Fruit.

To protect the fruit from being splashed by rain, nothing answers the purpose better than short stable litter taken just as it comes, but when so used it must be put on early in the spring, so that the rain may wash any manurial matter away, and allow time for it to become sweet and free from objectionable smells. In heavy lands or where slugs are troublesome, as they always are in Strawberry plantations where they abound, I have found the Bracken that has been used during the winter for covering up frames and other purposes to be the best protectors against these depredaters. After being knocked about and so thoroughly broken up as it is when done with in the spring, the splintered stems and numerous points that stick out in all directions are almost as sharp as needles, and form insurmountable obstacles to the slugs, so that any one pestered with them may, by using old Fern instead of straw, put such pests at defiance.

S. D.

THE GREAT FLOWER-PAINTERS.

JEAN BAPTISTE MONNOYER—BORN 1635, DIED 1699.

THE works of the celebrated French flower painter Monnoyer, known simply by the name of Baptiste among his contemporaries, are in every way a contrast to those of his great Dutch rival, Van Huysum. The works of Baptiste are almost always of a conventionally decorative character, and yet wrought with so much taste and skill, that in a distinct line of art they may rank as artistically equal to the truer, and in every way more natural works of the Dutch school. The best of his showy and yet graceful compositions are to be found enriching the white and gold panellings of the Trianon, at Versailles, at Marli, and in some of the apartments of the older portions of the Louvre. In these compositions he displayed an elegant and original method of grouping and balancing his designs that is truly admirable, and the flowers themselves, though compelled to play a specific part in the combination of those colour-harmonies in which he excelled, were at the same time painted with such an accurate perception of their forms, characters, and tone of colour, that the portraiture is always unmistakable. His Roses are touched off with a facile mastery that at once places them far above the rank of ordinary decorations; and though disposed of in arbitrary fashion to suit the general purpose and position of his compositions, they never lose the character of true Roses; and the same may be said of all the other flowers, the beauties of which he subdued, as it were, to his special purpose. The flowers he considered most amenable to his method of treating decorative art were Roses, Poppies, Anemones, Larkspurs, and Jasmine, most of which, under different and skilfully contrived aspects, are introduced in nearly all his compositions. He, however, managed to heighten and vary their general effects by means of rich adjuncts of various kinds; among which were superbly brocaded draperies, often enriched with heavy and glittering bullion fringes, gracefully falling over polished marble or porphyry slabs, in which both flowers and drapery were partially reflected with excellent artistic effect. He also introduced, still more frequently, richly-chased vases of gold or silver, painted with surprising realism, which imparted a majestic character and gave great solidity and importance to his decorative compositions. Occasionally, glistening helmets or even embossed cuirasses were made to take part in the arrangement of that elegant system of ornamentation which he may be said to have created, and which he carried to its highest pitch. He soon became celebrated all over Europe for his skill in interior ornamentation, and was invited to London by Lord Montague, along with his well-known countrymen, La Fosse, the facile painter of historical and mythological subjects, and Rousseau, celebrated for his architectural perspectives, which were often painted with such skill as for a moment to deceive the eye. The three French artists were employed upon the decoration of Montague House, especially on the staircase walls, and the panellings and ceilings of the more important apartments, upon which Baptiste lavished some of his rarest work. The artistic labours of these three French artists were not destined to a very long existence; they were swept away with the noble residence, of which they were the chief ornament, in order to obtain a site for the present British Museum. Jean Baptiste Monnoyer did not confine himself exclusively to decorative compositions, but occasionally condescended to be a simple painter of flowers, for themselves. Some of his pictures of this class have a charm entirely their own, arising from the free, and ever graceful and facile touch of the painter; but they all have, notwithstanding the easy freedom with which the grouping is managed, a certain character of ornamentalism rather than of natural treatment. Nevertheless, the beauty and ease of his characteristic delineations of each spray and flower will always be at once admitted as the meed due to the painter, as is well shown in the annexed specimen of one of the most successful of his simpler compositions, of which we are enabled to give a well-executed wood engraving. The seemingly careless play of the Poppies, and the high finish of the magnificent leaves, the glaucous green of which is so well rendered, are indisputable evidences of a master-hand, while the Jasmine sprays and the spike of Larkspur arc, with the other features of the composi-

Best Kinds of Strawberries for Forcing.—Generally, Strawberry forcing has not been a success this season, a circumstance which I attribute partly to the immature state of the crowns, occasioned by the wet, sunless autumn which we had, and partly to the absence of sunshine ever since the beginning of the present year. I may remark, however, that some kinds have done tolerably well, whilst others have failed. Vicomtesse Héricart de Thury has been extra fine for the season; President, moderately good; Sir Charles Napier, poor; and Keen's Seedling, bad. Has this variety, which used to stand at the head of the list, been crippled by over-production, both as to plants and fruiting?—H. W. W.

tions, equally successful in their dashing style, and serve to prove that in his special walk of art Monnoyer was an accomplished master.

PLATE LXXIV.

THE CLERODENDRONS.

(WITH A COLOURED FIGURE OF *C. SPECIOSUM*).

By THOMAS BAINES.

THERE are three very distinct sections of Clerodendrons that are extensively grown in stoves: one consists of deciduous twiners, of which *C. Balfouri* may be taken as a representative; a second is *C. splendens*, a variety of which is represented by the annexed plate; this is also a twiner, but differs from the last-named section in being evergreen and requiring different treatment; then comes the third division, which consists of evergreen shrubs very distinct, and which need treatment different from the others. A selection from these sections may with advantage find a place amongst the best collections of plants; they have much to recommend them, inasmuch as they grow freely and succeed with less attention than most subjects, not being impatient of either drought or moisture to such an extent as the generality of cultivated plants. The Chinese *C. fragrans* is one of the sweetest-scented flowers grown. Another advantage which Clerodendrons possess is—they can be flowered in either a large or small state, several of them being alike suitable for twining round a pillar or for draping a rafter; where room is a consideration, there is another property possessed by the shrubby species that is deserving of attention—it is the way in which they may be cut in every autumn, so as to occupy little room during the winter; not only will they bear this treatment without injury, but to keep them in their wanted shape it is necessary to so reduce their size as to literally head them down. As regards cultural requirements, let us commence with the shrubby kinds, of which we may take *C. fallax* as a good representative. This

is a vigorous-growing shrub, with ample, lively green leaves supported on stout petioles 8 in. or 10 in. in length; above these, from the points of the current season's shoots, spring the flowers, which are bright scarlet in colour and borne on very large stately erect panicles 10 in. in diameter and 1 ft. high. This kind strikes readily from cuttings, which can generally be obtained about the end of June. When they can be got 6 in. long, they should be taken off with a heel. They should then be inserted singly in 3-in. pots in half sand and finely sifted loam; the soil should be kept moist and the propagating-glasses sufficiently close to prevent the leaves from

flagging; these, from their size and somewhat soft texture, will not bear so much air as some kinds of foliage until roots are formed. They should be placed in a temperature of 70° at night and allowed 10° more in the daytime during bright weather. They will root in a few weeks, when the glasses may be removed and the plants placed for a week or two in a light situation; they should then be moved into 6-in. or 7-in. pots, according to the quantity of roots which they are found to have made when turned out of the cutting-pots. They should be potted in good fibrous loam, not broken too fine; to this should be added one-fifth rotten manure and an equal quantity of sand; make the soil quite firm in the pots, and place them on a shelf as near the glass as they can be got; this is important, in order to keep them dwarf and short-jointed, upon which, in a great measure, depends their good appearance afterwards more than in the case of most

Works of the great Flower-painters:—Vase of flowers by Monnoyer.

plants, for if allowed to become at all drawn, no subsequent treatment can furnish them with stout, healthy leaves down to the pot until they have been headed down, which would entail the loss of a season. They must never be allowed to suffer from want of water, or the leaves will be injured. Syringe freely every afternoon both the upper and under surfaces of the foliage; they will require slightly shading in very bright weather until the middle of September, when it should be discontinued; give more air, then cease syringing, and reduce the temperature to 65° at night and proportionately lower during the day, lowering it 5° more as the days get shorter.

During winter little growth will be made, and correspondingly less water must be given; but as these *Clerodendrons* do not require the wood to be ripened so much as that of most hard-wooded plants, they must never be allowed to get too dry at the roots so as to cause the leaves to flag, or they will be injured. Keep them where they will have plenty of light, and continue this treatment until the middle of February, when the temperature should be raised 5° day and night and the plants moved into 10-in. pots, now using the soil in larger pieces than before, but with a similar quantity of manure and sand added. After this be careful not to give too much water until the roots have got well hold of the soil; towards the end of March raise the temperature 5° more, and begin to syringe overhead in the afternoon; they will now grow fast, and should have a little air in the daytime; as the sun gets powerful, a slight shade will be necessary in the middle of the day. They make roots very freely, and by the end of April they should be moved into 13-in. blooming pots, which size will be large enough for the present season, using soil such as that recommended for the previous shift. The temperature may now be kept at 75° at night if the plants be required to flower early in the season, but with this heat they must be placed near the glass, and be allowed a moderate amount of air every day. About the beginning of June they should show bloom, when they may have manure-water given twice a week; in a few weeks the flowers will begin to open, when the plants can be moved to the coolest end of the stove, or if a house be at hand where an intermediate temperature is kept up, they may be removed to it, which will prolong their time of blooming. When the flowers are over, if the spike be cut out at the bottom, just above where it springs from the upper leaves, and the plants be again subjected to a brisk heat, they will push up one or more shoots from the point where the flower-stem was removed, and will bloom again towards the end of August or beginning of September; after this they may be cut down to within 8 in. or 10 in. of the bottom, and should be kept about 65° at night and a little higher in the daytime, syringing daily, but not giving much water to the soil until they have again begun to grow; the temperature may be lowered as in the preceding autumn, wintering them as before. As the days lengthen give more warmth in March, take them out of their pots, and remove one-third of the old soil, putting them in pots 2 in. or 3 in. larger; press the soil moderately firm, and treat them in every way as during the previous summer, except that they will not require potting a second time; they will flower again twice, but this time they must not be cut back after the first flowering, further than just removing the flower-stems. Plants thus treated will last for years, and may if desired be grown in 18-in. or 20-in. pots, in which way they will attain a large size, bearing eight or ten spikes of bloom at a time.

Clerodendron Kæmpferi.—This handsome South American species also bears scarlet flowers, and like *C. fallax*, it can be raised from seeds sown as soon as ripe in autumn, but in order to obtain them the first flower-stems must not be removed, but allowed to remain on the plant until the seed is matured. Sow the seeds singly in small pots, covering them with $\frac{1}{4}$ in. of soil, they will soon vegetate, and will require treating in every way similar to young plants raised from cuttings.

C. fragrans fl.-pl.—This is a weaker-growing plant than the preceding, producing close compact heads of pinkish-white double flowers, so highly yet agreeably scented as to be preferred by many to those of *Daphne indica*, *Tuberose*, or the old *Clove Carnation*. It requires similar treatment to the two first-named kinds, but does not need so much root-room. It is a native of China. All the above are sufficiently stout in their habit of growth as not to need much support, except a single stick to each flower-spike.

C. splendens.—This is an evergreen twiner of moderate, but not very quick growth; the flowers, which are deep scarlet, are produced in slightly drooping panicles from the young wood, and are very handsome. This species is well adapted for clothing a pillar or rafter, and looks well trained on a moderate-sized wire trellis. It is from *Sierra Leone*, and can be propagated by means of cuttings, but these require to be selected with judgment, as, if made from hard wiry shoots they do not either root or grow freely, and, on the other hand, if too soft they generally damp off. The best cuttings are those obtained from a strong mature branch that has been cut back; the young shoots that afterwards break from it should be taken off with

a heel when about 8 in. long; these can be got in the summer, and will root in sand; they should be placed singly in small pots under a propagating glass in a temperature of 75°, and when well rooted they should be moved into 6-in. pots in fibrous peat, to which has been added one-sixth of sand. When they begin to grow place a stick in each pot for support, giving them a light situation, with air every day, and shade when the weather is such as to require it, syringing overhead when the house is closed until autumn; reduce the heat 5° day and night as the sun gets less powerful, and in winter a night of temperature of 65° will be sufficient. About the middle of February give them 5° more warmth, which will set the roots moving, and a month afterwards move them into 10-in. pots, again using good peat and enough sand to keep it open; pinch out the points of the shoots in order to induce them to break back. During the spring and summer they will bear a temperature of 75° at night, giving air when the thermometer rises to 80°, shading in sunny weather during the middle of the day, syringing freely overhead when the house is closed, which should be done early in the afternoon. As the growth requires support, put in each pot four or five sticks, round which train the shoots, but do not allow them to become entangled one with another, which often happens if not attended to. Keep them in these pots during the season, again lowering the temperature in autumn, and discontinuing the use of shading and syringing; winter them as last year, gradually raising the temperature when the days lengthen sufficiently to require it. About the same time in the spring shift them into their flowering pots, which for this first season should be about 13-in. ones, put in soil similar to that previously recommended, and place a wire trellis to each plant, over which train the shoots evenly. Give heat, shade, and air as during the previous summer, and also water to the roots and overhead. By midsummer they may be expected to show flowers, which will continue to open and remain in good condition for several weeks, during which time the plants may be placed where they can be kept a little cooler, but they must not be set where they will be subjected to draughts or to too low a temperature, or the flowers will fall off before they open. Keep the shoots regularly trained as hitherto; after the blooming is over, they may, if too full of growth, be slightly cut in and kept through the autumn and winter as before. Again about the time that growth is commencing the plants should be turned out of their pots, removing any loose soil that may exist; but they must not be shaken out, as is often done in the case of deciduous subjects, or the leaves will suffer; move them into pots 3 in. larger, using soil the same as before, and treating them in every way similarly. They will last for many years by removing a little of the surface-soil each spring without disturbing the roots too much; they will also be benefited by having manure-water in the growing season. When this *Clerodendron* is used as a climber it is better to grow it in a pot, as from its moderate habit of growth the roots are not so well calculated for planting out. *C. speciosum*, which is a handsome variety of *C. splendens*, may be treated in every way like it.

C. Balfourii.—Among deciduous, twining *Clerodendrons* this is much the best. It is a vigorous, quick grower, and may be either planted out or grown in a pot, for which latter purpose it is well adapted either for flowering in a small state or for growing into large specimens. It strikes freely from cuttings, which should be taken off with a heel as soon as they are 8 in. long, and if the plants have been started about the beginning of February, the cuttings will be large enough to take off in April. Put them singly in 3-in. pots filled with two-thirds sand to one of loam sifted fine; being very soft, they require to be kept moist or they will flag if much air be given; keep them until rooted under a propagating glass in a night temperature of 70° with a little more heat during the day; give just as much air as will prevent damping; they will root in a very short time, after which place them where they will receive a fair amount of light for a few weeks; then move them into 6-in. or 7-in. pots. The soil should consist of four parts good, turfy loam to one of rotten manure and sand in equal quantities, press it firmly in the pots and pinch out the points of the shoots to induce their branching out; let them have plenty of light and water freely; when the roots have begun to move well they will bear a temperature of 75° at night and 10° higher with sun-heat, syringing overhead at the time when the house is closed. When the shoots have grown three or four joints past the point they were first stopped to, they should be again stopped. By the end of July they want moving into 10-in. or 12-in. pots, but this time do not break the soil fine; each pot should now have four or five sticks a yard high placed just inside the rim, round which to train the shoots; very little shade is required, full exposure to the light being necessary to induce their flowering profusely; give a moderate amount of air all through the summer and increase it in September, at the same time discontinue the use of the syringe. About the close of the month water should be withheld from the soil until the leaves flag considerably, after which give a little to

freshen them up, again allowing the soil to become dry so as to cause the foliage to droop before water is applied; keep on repeating this process, which will stop further extension of their shoots, harden up the wood, and ultimately cause the leaves to turn yellow and fall off; after that reduce the temperature to 55° during the winter, giving no more water than will just keep the soil slightly moist. When starting them into growth, which may be at any time from the end of February to May, they must have the ball of earth well moistened at the time when they are subjected to a higher temperature; this will be best managed by soaking them in a pail of tepid water, letting them stand pot and all in it for twelve hours; after this raise the heat 5°, at the same time training the shoots neatly round the sticks; when they have made a few inches of growth, the temperature may be raised to 65° at night, giving 8° or 10° more during the day. Syringe regularly overhead in the afternoon; in a few weeks they will show flower which will grow rapidly, and as a rule begin in 8 weeks from the time the plants were first started. If bloomed early it will be necessary to keep them in a temperature similar to that in which they have been brought on, but if not flowered until later they may be moved when in bloom to the conservatory, where they will last in good condition for several weeks. After this they may be at once shifted into 16-in. or 18-in. pots; the shoots should then be nipped from the sticks, cut back to 4 ft. or 5 ft. in length, and each plant trained near the roof in a house or pit where they will receive plenty of light, with a temperature during summer such as that of the preceding summer, treating them in other respects similarly, and drying them off in autumn as before. After this a strong wire trellis should be fixed on the pot, over which the shoots may be evenly tied. Winter them in a similar temperature, and again bring them into flower when required. After blooming this season they should be well cut back, turned out of their pots, and one-third of the ball of earth removed, replacing them in the same pots in new soil and growing them through the season as recommended for the last. They will now be benefited by manure-water when growing; managed in this way they will last for several years. If required for planting out, they should have a well-drained border in which there is not too much room for the roots, or over-luxuriant growth may be the result; the soil ought to be similar to that which has been recommended for pot culture, drying the plants off similarly in autumn. After the first season a little of the surface-soil should be removed each year, replacing it with fresh material, and giving manure-water liberally: cutting well in each season after flowering. C. Thompsoni and C. Rollisoni will succeed under the same treatment.

As regards insects deciduous Clerodendrons are not much subjected to them: red spider will sometimes make its appearance, and, if not removed soon, injures the leaves. For this the best preventive is a free use of the syringe. The shrubby species are often attacked by both brown scale and mealy bug; but diligent use of the syringe and sponging will keep them in check. When they are headed down affected plants should be well washed with Insecticide. The large-leaved kinds are sometimes infested with red spider, if the under sides of the leaves be not kept well syringed. C. splendens and C. speciosum should be treated similarly if troubled with insects.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Sweet-scented Amaryllis.—Is it customary for the blooms of Amaryllises to be sweetly perfumed? I was not aware of it until this spring, when for some days passing an example of a garden hybrid in my greenhouse, I was struck with a most exquisite perfume, which I found proceeded from this plant. —JOHN E. DANIEL, *Epom.*

Draining Cutting Pots (see p. 352).—Inverting a flower-pot within another for drainage is by no means new; on the contrary, it is generally done in the case of soft-wooded plants and also in that of other plants that require a good, brisk bottom-heat. Seeds such as those of Cyclamens, Cinerarias, Primulas, &c., may also be raised successfully in pots drained in this way.—G. A. D., *Windsor, Essex.*

Adiantum Farleyense as a Basket Plant.—In no way can this beautiful Fern be better grown than in wire baskets suspended from the roof of the house in which it is kept. Thus treated, the fronds hang down gracefully, and under favourable circumstances the crowns of the plants soon cover the soil both at top and bottom. This Fern looks well cultivated in this way.—S.

Narcissus Bulbocodium in Pots.—The Yellow Hoop-Petticoat Narcissus forms an attractive pot plant during March and April, if grown under advantageous circumstances. For this purpose bulbs of it require to be potted early in autumn, five or six being placed in a 6-in. pot, and set in a cool frame or pit, protected from frost and heavy rains. Thus treated, they will flower several weeks earlier than out-of-doors, and the blooms, which are of a more delicate texture, are drawn well up above the foliage. Such plants form effective objects for front rows on conservatory stages, or for placing in vases or on window-sills.—C.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vines.—Thin Grapes when the berries have attained the size of small Peas; any delay after that time is attended by two evils, viz., the work is much more difficult to perform, and the impossibility of using the scissors without rubbing the berries that are to remain. In Grape thinning amateurs are more frequently led to make mistakes than in almost any other operation in gardening. When Vines are strong and healthy, a great many more bunches are formed than they are able to sustain, and there is too often a great reluctance to reduce their number sufficiently; the result of this is overcropping, which, especially whilst the Vines are young, frequently injures them to such an extent that they never thoroughly recover. It is a common occurrence to see healthy, strong Vines allowed to carry as much fruit in the second or third year of their bearing as they ought to have borne in two years, during which season, if attentively noticed, they will be seen to have scarcely grown perceptibly thicker; whenever this occurs, the wood of which the young rods are composed becomes prematurely solidified, and will never afterwards acquire the same size and strength that it would have done had the Vines not been overburdened with fruit. The evil may be in some measure corrected by bringing up a young cane from near the bottom, or within 2 ft. or 3 ft. of the ground; but although this, if fairly treated, will often attain a thickness and strength of which the overcropped cane from which it proceeds is not capable, still the injury done in the first instance can never be fully repaired. Vines the second year after planting, however well they may have grown, should not be allowed to carry more than two or three moderate-sized bunches, the third year six or seven, the fourth about a dozen, and the fifth—at which time, if all have gone well, they will have furnished the full length of the rafter—they may be permitted to bear from eighteen to twenty, according to the size of the bunches, for it is not the number that tells upon the energies of the Vines, but the collective weight of the fruit. The fruit-bearing capabilities of Vines when in good condition are in a great measure regulated by the head-room they have, with length of rafter and number of canes allotted to each Vine; for instance, in a house that admits of their attaining a length of from 20 ft. to 24 ft., they will bear without injury a correspondingly greater weight of fruit than where they have only room to become 16 ft. or 18 ft. long; in like manner, when a Vine is furnished with from two to six rods, with sufficient room and good soil for proportionate root development, the bearing capabilities of each rod will be almost equal to the one cane of Vines confined to a single rod. In all cases it is much better to undercrop than overcrop. A healthy, fully-established Vine, with the ordinary length of from 18 ft. to 20 ft. of rafter, will bear every year from 18 lb. to 24 lb. of Grapes and mature them thoroughly, providing the foliage be kept clean and healthy through the season and free from its worst enemies, red spider and thrips. In all cases where the house is exclusively devoted to the Vines and no plants are grown underneath, retain as much foliage as admits of exposure to the full complement of light, for the more well-developed leaves they carry the more strength and vigour the Vines will attain, but on no account should the foliage be allowed to become crowded, for where one leaf grows over another, the under one, being deprived of sun and light, is so thin, soft, and weak in texture as to be unable to perform its allotted functions, and has a weakening rather than a strengthening influence upon the Vine. Where plants must be grown it is better to reduce the number of Vines by having them further apart, so as to allow as much light as possible in between them, instead of keeping the shoots of the greater number of them shortened in too closely. Keep all laterals stopped in close. With old Vines that have become somewhat exhausted through overbearing or the ravages of insects, I should recommend the young rods to be taken up from the bottom. A number of shoots are usually each spring emitted from the stem within 2 ft. or 3 ft. of the base; select that in the best position, the lower down the better; if this shoot be encouraged it will generally reach the top of the house the first season. At the time of pruning it will require shortening to about one-third its length, cutting the bottom spurs of the old cane completely away up to this point to make room for the bearing shoots of the young one; the third year it will occupy all the space, previous to which the old cane must be cut away. Stop and thin the shoots of late Vines.

Peaches in Houses and upon Open Walls.—In the house first started the fruit by this time will have stoned, and should receive the final thinning; here, again, it will be well not to allow the trees to carry too many fruit, for, although overcropping in the case of the Peach does not inflict permanent injury to so great an extent as it does with the Vine, it is nevertheless injurious, and its effects for the present year on the fruit will not only cause it to be

much smaller, but also deficient in quality. Remove all superfluous shoots that will in any way overcrowd each other, or shade the fruit; to prevent which, tie in the young wood remaining, and remove all leaves that overlap the fruit, as, where there is any interception of the sun's rays after this time it will not be well coloured, which so greatly improves its appearance and flavour when ripe. See that the soil in which the roots are placed is well supplied with moisture; a deficiency in this respect now would be more hurtful to the current crop than at any other time, as the demands upon the roots are at the utmost. Syringe freely and continuously, getting the water well to the under side of the leaves, where red spider first effects a lodgment; it generally makes its appearance about the base of the trees, and whenever the leaves assume a slightly yellow hue they should be examined, and if the insect be found before it has had time to spread, and the leaves be carefully sponged with weak Gishurst water, in the proportion of 2 oz. to the gallon, it may be stopped from extending farther; but, where the syringe is carefully used daily, so as to wet the leaves on both their upper and under surfaces effectually, it will not make much headway till the fruit begins to ripen. Thin the fruit and disbud in late Peach-house, tie in the shoots, and here also use the syringe freely. Peaches on open walls should be well syringed two or three times a week, the long, protracted, cold winds we have had having checked their growth to such an extent as to make them much more subject to the attacks of aphides.

Cucumbers.—Thin out the shoots of the earliest Cucumbers before they become too much crowded, thereby preventing a manifest waste of strength. They will be maintained in a healthy-bearing condition until the end of the season, if all unnecessary growth be removed as it makes its appearance; it is also essential that the plants be kept quite clean from aphides and red spider, which must never be allowed to obtain a footing. As soon as a fruit is perceptible, pinch the point off the shoot immediately beyond it; where the growth is permitted to run a joint or two farther, it always has a tendency to cause too much crowding, to the great injury of the plants.

Melons.—Regulate the growth of Melons as it proceeds, thinning the shoots moderately, but not to such an extent as with Cucumbers. Pot off the last-sown Melons to be transferred to frames set at liberty when cleared from bedding plants, putting them either in the early Melon frame or on a separate bed to themselves. Manure should now be got ready, well shaken up, and watered more or less according to its dry or wet condition, for beds for late Melons, which must be at once made up, or the summer will be too far advanced before the fruit gets ripe.

Vegetable Marrows.—Where these are required early a slight hotbed should be made for them, on which place a frame, turning the plants out in it; by the time they have filled it the weather will be sufficiently warm to admit of its being removed altogether. Sow more seeds in a hotbed, Vinery, or greenhouse, planting out next month.

Tomatoes should now be placed in a cold frame with plenty of air during the day, so as to have them well hardened before planting; where they are turned out whilst in a tender state, even if the ensuing weather be fine, they frequently remain dormant for two or three weeks, which seriously interferes with the quantity of produce, as if the growth be at all checked, most of the warm weather is over before the first fruits are ripe.

Roses will require special attention, as the maggot is making its appearance in large quantities, and unless promptly destroyed now whilst curled up in the leaves before the buds get to any size, the greater portion of the flowers will be rendered worthless. To destroy, and, what is still better, to prevent aphides, syringe freely with soapy water; this, if effectually applied two or three times, will kill those that are matured, and be so distasteful to them through the sediment which it leaves on the foliage, that the females do not deposit their eggs where it is present.

Kitchen Garden.—More Peas should be sown, and everything possible ought to be done to insure their bearing freely and to prolong the season of their produce, as the early sowings in many localities promise to be comparative failures, the cold weather and cold state of the earth having produced but a stunted, slow growth, and thereby exposed them for a longer time than usual to the ravages of birds and slugs, which have been more than ordinarily troublesome. In many places, particularly in the driest parts of the country, the greatest difficulty to contend with in these later sowings of Peas is mildew; the best preventives to which are an open situation fully exposed to the sun and air, thin sowing, with plenty of room between the rows, with a good quantity of manure dug in deeply so as to support the roots when they have descended a considerable depth. To effect this latter purpose open a narrow trench for each row 12 in.

or 15 in. wide and one spit deep, digging in 6 in. of good rotteu manure in a moist condition; then draw in the soil that has been taken out in sufficient quantity to leave the trench about 4 in. deep after it has been moderately trodden with the feet, in which sow the seeds, covering them with the remainder of the soil taken out; so treated, with copious waterings in dry weather from the time they bloom onwards, they will keep on bearing without mildew in situations in which it is possible to avoid that parasite.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

May 21.—Potting Vesuvius and Dr. Lindley Pelargoniums for autumn blooming; also young Cyclamen, afterwards placing them in heat and shading them during the day. Blocking Dendrobium Devonianum, and shifting Phaius albus from baskets into pots. Sowing Mignonette in 6-in. pots for house decoration, and another crop of Negro Long-pod Bean and Maclean's Wonderful Pea; also sowing a little Chervil in boxes and in the open border. Planting a border with April-sown Cauliflowers; also Celery and Lettuces, and making another plantation of Cabbages, Savoys, and Brussels Sprouts. Pricking out Lettuces under glass protectors on a bed of manure. Removing rank laterals from Vines, and thinning late Grapes. Placing Tomatoes out-of-doors to harden off ready for planting. Watering Potatoes in pits; also young Celery and Radishes. Topping the shoots of Broad Beans which are in flower. Preparing flower-beds for planting. Turning Mushroom manure in order to sweeten it and prevent it from getting too hot. Tying in shoots in Peach-house, and re-filling conservatory baskets with Tropaeolums.

May 22.—Potting-off Chrysanthemum cuttings and Gesneras. Shifting Chilies into 8-in. pots, and Salvia splendens into 10-in. ones. Blocking Dendrobium Falconeri and D. Bensoni, and re-potting Vanda insignis. Sowing Scarlet Invincible Sweet Peas for succession; Walcheren Cauliflower, Knight's Tall Marrow, and Champion of England Peas; also Syon House Cucumbers. Planting Iresine, Cerastium tomentosum, Vegetable Marrows, and Ridge Cucumbers. Putting in cuttings of several varieties of Cliveden Pansies. Watering second Vine and third Peach borders with sewage; also watering Yew trees that have been recently transplanted. Syringing Peach trees out-of-doors in order to keep off insects. Earthing-up Potatoes as fast as they appear above ground. Thinning Carrots, Turnips, and Beetroot. Clearing away Spinach that is of no more use, and manuring and digging ground for other crops. Hoeing and otherwise cleaning Onion beds. Turning manure ready for Melons. Digging land for planting Brussels Sprouts, Cabbages, and Savoys.

May 23.—Basking in Moss Dendrobium Lowi, and also Odontoglossum coronarium and O. Phalopsis. Sowing Sutton's London and Paris White Cos and Neapolitan Cabbage Lettuces, Spinach, Beet, and Radishes. Planting out Scarlet Sweet Peas that have been raised in pots and duly hardened off; also Tropaeolum canariense, Gnaphalium, Centaureas, and Zonal Pelargoniums. Thinning late Grapes; also Parsnips. Watering French Beans and Cauliflowers under glass cases and hand-lights; also Celery in trenches and newly-planted Cauliflower plants. Preparing pit for planting out Cucumbers. Staking Scarlet Runners and Peas as fast as they require support. Throwing out more Celery trenches, and making them ready for receiving the plants. Hoeing and raking shrubbery borders. Levelling land for late Peas. Tying Peach trees in late house.

May 24.—Potting double Wallflowers and Selaginellas; also Cattleya exoniensis, C. Warneri, and Dendrobium speciosum. Sowing another batch of Balsams, Iberises, Wallflowers, and Pentstemon; likewise Brompton Stocks, Alyssum, and Oxalis. Planting French Beans that have been raised in pots into cold pits and on south borders. Digging land for late Peas and putting in ridge of soil in Cucumber-house ready for planting. Manuring Celery trenches. Emptying and refilling Melon pit ready for planting, and making a ridge for Vegetable Marrows. Giving more air to Peaches and Nectarines that are ripening both night and day with a view to improve their flavour. Putting short Grass between Strawberry plants on which the fruit has set. Preparing land for sowing annuals, tying creepers in conservatory and on the verandah, and removing Balsams that are coming into bloom to conservatory.

May 25.—Shifting Celosias into 10-in. pots, and placing them in a warm pit. Potting Mimulus for the conservatory; also Ice-plants and Fuchsias, and repotting Lælia purpurea. Sowing Rudbeckias, Polyanthuses, and Myosotis; also French and Long-pod

Beans, Champion of England Peas, and another crop of summer Spinach. Planting a small bed of White Celery to come into use for kitchen purposes early, and pricking out young Celery plants in open border. Watering orchard-house. Removing Tomatoes to cold pit. Disbudding Peach trees out-of-doors, and thinning the fruit, so as to leave three to a shoot; also thinning Apricots for the first time, and nailing in all leading shoots. Examining Rose trees for maggot, and washing Orchids.

May 26.—Potting *Humeas* into large pots, and placing them out-of-doors; also *Calceolarias* and *Primulas*. Shifting young Vines into 10-in. pots, and placing them in Vinery. Sowing Invincible Scarlet Sweet Peas, Giant Emperor Stocks out-of-doors, and Intermediate Stocks in boxes placed in a warm frame; also sowing French Beans in pots for planting out, and placing them in heat. Planting a few Chilies out-of-doors in the warmest situation available for them. Transplanting Beetroot where seedlings have failed. Watering seed beds with guano water; also all kitchen garden crops that are likely to suffer from drought; likewise young Cherry trees, and afterwards mulching the roots with half-rotted manure. Tying in leading shoots of espalier fruit trees. Earthing-up Cucumbers that are growing freely.

Hardy Flowers.

ANNUALS.—These should all now be sown without delay. Many annuals are very pretty, but they often disappoint because a bad selection is sometimes made, and also because they are too frequently badly sown. In a deeply-stirred soil, enriched by some good compost, they cannot fail to do well, and be, on the whole, very satisfactory. *Acroclinium roseum*, Sweet Alyssum, *Calandrinia speciosa*, *Campanula Lorei*, blue and white; Candytufts, *Clarkia Tom Thumb*, *Collinsia bicolor*, *Dianthus chinensis*, *Gilia laciniata*, *Jacobaeas*, *Leptosiphons*, *Mignonette*, *Nemophilas*, *Portulacas*, *Sanvitalia procumbens* (double), and the dwarf *Silenes*, would make a good selection for small gardens. If growers of annuals would not only sow a little thinner, but also pull out the plants after they have grown to make room for the stronger, they would get much better plants and flowers than they now do.

ASTERS.—These should be got out into beds without delay, or, if in the mixed border, they should be put in groups of five or six plants. Those who grow Asters for exhibition not only plant them out in richly-manured beds, but put the plants in little trenches, which are mulched with manure during the summer, and by means of which liquid manure can be applied. The Aster is not a large-growing plant, and it is expected to supply good and fine blossoms, which it cannot be expected to do unless it be generously treated.

CROCUSES.—The leaves of these have grown this spring with unusual strength, but they ought not to be removed till they decay. The old-fashioned plan of tying together in a knot a few leaves is the one to be recommended on the score of tidiness. It is a mistake to allow Crocuses to dry up during the summer; they should be kept moist at the roots, and an occasional watering with manure-water is now to be recommended. Such species as *Imperati*, *speciosus*, &c., which have been flowering in pots, should now be potted off, placing five or six bulbs in a 4½-in. pot, in some good soil, and setting them out on an ash-bed in a shady place for the summer and autumn.

HOLLYHOCKS.—As the rainy weather is greatly assisting these plants to make growth, the flower-stems should be tied to strong stakes as they increase in height. The destructive disease which affects the under sides of the leaves with a kind of rust is manifesting itself in places, and, if hot, dry weather set in, will work sad havoc with them; a strong dose of Gishurst Compound has been recommended, washing the under sides of the leaves with it. Moisture at the roots inducing an exuberant growth, may assist the plants to overpower the disease to some extent.

INIAS AND SPARANIS.—These are now blooming freely in pots in a cold frame, and very beautiful they are. Quite a show of these beautiful flowers, together with others of a somewhat similar character, is presented to the London public, when Messrs. Hooper & Co., of Covent Garden Market, and others, make a point of exhibiting them at the meetings of the horticultural societies held during the time they are in flower. Well-drained pots, a light, peaty soil, and a fair amount of moisture are necessary to their success. They will grow and flower in the open air, but only under very favourable circumstances.

PANSIES.—The best-named kinds in beds will need fastening by pegging down the main branches, stirring the surface-soil, and occasionally top-dressing. The plants will need shading if flowers be required for show purposes. The bedding varieties are now getting effective; the richest blue is Blue Beard; the most effective blue *Viola*, Royal Blue.

PINKS.—As the Pink is always a free bloomer, a little disbudding later on is advisable, as the flowers will become fuller and finer. The main stems should be trained to neat sticks, and the bed stirred and top-dressed from time to time.

PRIMROSES.—It is a good plan to plant out choice Primroses both double and single during the summer. A bed should be prepared for them, having at the depth of 6 in. or 7 in. a layer of cow manure to make a cool bottom, and in 4 in. or 5 in. of a good, light soil. The plants should be turned out of pots and planted with unbroken balls, pressing the soil firmly about them, and planting somewhat deeply. They make strong plants during the summer, and can be divided when repotted in the autumn.—D.

VEGETATION OF THE PARAMOS OF NEW GRANADA.

WITH all the wealth of our gardens there are many curious types of vegetation still quite unrepresented, or only met with

Flower and Leaf of *Espeletia corymbosa*.

in botanical gardens. It is true that the majority of these forms of plant life are more curious than beautiful, but to the naturalist they often afford more pleasure and information than the more showy members of the vegetable kingdom. Usually they are characteristic of particular regions, and, in some instances, of very limited areas. Our indigenous flora even affords plenty of illustrations of the peculiarity of certain plants to certain soils and situations, though not one well-marked species is confined in its area of distribution to the British Islands; moreover, they stand out as distinctly in their several habitats as the characteristic types of the different regions of other countries. Take, for instance, *Glaucium luteum* on the sea-shore; *Narthecium ossifragum* in boggy ground; the several species of *Ophrys* in chalk or limestone; and the Alder and Willows of river banks and wet places, and the Birch of elevated, dry places. Turning to the New World, to the Andes of New Granada, we find at an elevation of 12,000 ft. to 14,000 ft., the strange type shown in the accompanying illustration associated with species of such British genera as *Cerastium*, *Erodium*, *Hypericum*, *Gentiana*, *Cardamine*, *Pinguicula*, *Poa*, *Festuca*, *Carex*, &c., besides a host of others peculiar to the region. It is in the open, almost treeless plains and hill-sides, called Paramos, that they abound. Paramo, it should be observed, is a Spanish word, signifying a cold, exposed country of a desert character, though probably not desert in the extreme sense of the word. The plant, which forms the most striking object in the scenery, is a member of the *Compositæ*, belonging to

the genus *Espeletia*, which is closely allied to the more familiar *Polymnia*. The entire genus comprises about a dozen known species, varying from dwarf tufted plants to tall, single-stemmed herbaceous plants like *E. corymbosa*, or shrubby or even arborescent in one species. *E. corymbosa* and some of the others have the epidermis of the leaves clothed with a dense, felt-like mass of soft hairs, similar to those of *Hermas gigantea*, an umbelliferous South African plant, and *Andromachia igniaria*, another member of the Compositæ, growing in Peru; specimens of both of which may be seen in the museum at

panicles from the centre of the tuft of leaves. A dwarfier species, *E. argentea*, is figured in the "Botanical Magazine," plate 4480. This was collected and introduced by the botanical collector Purdie, in the Paramo of Siejo, New Granada; and was in cultivation both at Kew and at Syon House in 1848. The woolly covering of the leaves of this is of a silvery-white, in others it is in various shades of yellow-brown, and the flower-heads yellow, with a purplish centre. In other respects it is a relatively miniature species. One remarkable property of the species of *Espeletia* is that they abound in an aromatic,

Espeletia corymbosa in New Granada.

Kew. In both countries this felt-like epidermis is used as tinder. *E. corymbosa* and *E. grandiflora* grow to a height of 8 ft. or 10 ft., with a trunk several inches in diameter. The lower part of the trunk as the plant grows becomes naked, as shown in the illustration, and bears at the top a dense tuft of leaves, often matted together with the hair of the epidermis. The thicker part of the trunk immediately below the leaves is clothed with the bases of fallen leaves. The yellow and purple flower-heads are small, in the largest less than 2 in. in diameter, and borne in the caulescent species in small, slightly-branched

fragrant resin, which is used as incense, and also by the printers of Santa Fe de Bogota in the composition of their ink. It is stated that the Spaniards call some of the species of *Espeletia* and *Calceitium*, Frailejon or Frailejon. What the meaning of the word is I cannot say, as I find nothing approaching it in my Spanish dictionary. W. B. H.

Aquatic Plants in Regent's Park.—The Blue Water Lily is now flowering freely in a tank in the Botanic Gardens, and associated with it are plants of *Limncharis Humboldtii*, bearing numbers of bright orange Poppy-like blossoms.—S.

THE HONEYSUCKLES OR LONICERAS.

By GEORGE GORDON, A.L.S., Author of "The Pinetum."

ALL the upright-growing hardy species of these are well adapted for shrubberies; they succeed in any common garden soil, and most of them also offer an easy opportunity of improvement by intermixing the fragrant and more vigorous growing kinds with the yellow and scarlet flowering Caprifoliiums. Of the latter a full account was given at p. 87 of the current volume.

Section I.—The Xylosteums, or Fly Honeysuckles.

Short axillary funnel or campanulate flowers—two-bracted at the apex, with the calyx generally deciduous; the fruit distinct, not crowned, in pairs, more or less three-celled in the young state, and when ripe either scarlet, bright red, or black. The leaves mostly hairy, thin in texture, and soft.

Common Honeysuckle (*Lonicera Xylosteum*).—This is a robust, deciduous shrub, 8 ft. or 10 ft. high, of little beauty, but well suited for forming thickets and screens in gardens. Its leaves, which are ovate, are set on longish foot-stalks, and are densely hairy. The flower-stalks, appear in July, are small, cream-colour, when young, but much deeper-coloured before they fall; they are produced in axillary pairs, with hairy bracts which are much shorter than the leaves, and quite downy; the berries are oval, distinct, scarlet in the common form, one-celled and six-seeded. This species is found throughout nearly the whole of Europe, in thickets, hedges, and rocky places. It is also said to be a native of Britain in similar situations. It is the *Xylosteum dumetorum* of ancient writers and the *X. vulgare* of Loddiges. There are three varieties of it, which differ from each other in the colour of the flowers and berries; one (*L. leucocarpa*) has whitish fruit, another (*L. xanthocarpa*) has yellow berries, and the other (*L. melanocarpa*) has black fruit; the wood is hard, and the young shoots have a greyish-white colour.

Various-leaved Honeysuckle (*L. diversifolia*).—This is a robust, deciduous shrub, 5 ft. or 6 ft. high, with villous branches. The leaves, which are ovate, are rounded or sub-cordate at the base, downy, and set on short, smooth footstalks, bracts ciliated with long hairs; the flowers, which appear in July, are axillary, shorter than the footstalks, in pairs, pale yellow, and resemble those of the common Fly Honeysuckle both in size and shape; berries rather large, globular and black. It is a native of Nepal and Kamaoa, where it is found in thickets. The *Lonicera Roylei* of the Nepal Mountains, is a variety of this, with oval leaves and longer footstalks.

Privet-leaved Honeysuckle (*L. ligustrina*).—This is a slender shrub, covered with ash-grey, shining, smooth bark, with the young shoots villous; the leaves are ovate-lanceolate, dark green above, pale beneath, shining and ciliated, they are obtuse at the base, acute at the apex, with villous footstalks; the flowers are axillary, on very short footstalks, they are yellowish-white and funnel-shaped, tube gibbose, pubescent at the base and villous within, bracts two at the apex of each footstalk; berries distinct, three-celled, with three seeds in each cell and covered by a common membrane. It is a native of Nepal in mountain woods; flowers in July.

[Synonyms—*Xylosteum Nintoo* and *Lonicera ligustrina* of Professor Don, in his "Flora of Nepal."]

Himalayan Honeysuckle (*L. acuminata*).—This kind has villous branches and leaves varying from ovate to oblong, cordate at the base, slightly hairy, membranous, and from 3 in. to 5 in. long; the flower-stalks are axillary, longer than the petioles, villous and two-flowered; the bracts are linear, acuminate, and ciliated; the corolla is funnel-shaped, yellow, tinged with pale purple, slightly hairy on the outside, and like those of the common Fly Honeysuckle; the berries are globose and black. It is a native of the Himalaya Mountains; flowers in July.

Georgian Honeysuckle (*L. Iberica*).—This forms a very neat, low-spreading shrub, and is well adapted for garden hedges; it grows 3 ft. or 4 ft. high, with cordate, roundish, tomentose leaves; the flowers are axillary, in pairs, and shorter than the leaves; the bracts are oblong and ciliated; the corolla is of a dull yellowish-green colour, and like those of the Alpine Honeysuckle in size and shape; the berries are joined together, globose, and blood-red in colour. It is a native of Georgia about Tiflis; flowers in April and May.

[Synonym—*Xylosteum Ibericum*.]

Downy-leaved Honeysuckle (*X. canescens*, Loddiges).—This neat but not showy kind has twining branches, and forms a deciduous shrub 4 ft. or 5 ft. high; the leaves and stems are canescent from down, ovate, cordate, bluish, and petiolate; the peduncles are two-flowered and longer than the flower-stalks; the bracts and lobes of

the calyx are oblong; the flowers are two-lipped, attenuated at the base, pale yellow, and velvety on the outside; the berries are nearly distinct, globular and black. It is a native of Mogador, Mauritania, Sicily, and Palermo, growing in hedges; flowers in June and July.

Ciliated-leaved Honeysuckle (*L. ciliata*).—This kind forms an erect, deciduous shrub, from 4 ft. to 6 ft. high, with ovate or oblong, cordate, thin ciliated leaves, villous beneath in the young state; the peduncles are elongated, axillary, with two flowers on each, which are very much shorter than the young fruit, and distinct; the flowers are bluntly spurred at the base, with short, acute, nearly equal segments; they are white with a tinge of red or yellow, and with the tube ventricose above; the berries are distinct and of a red colour. It is a native of North America on mountains and among rocks in rich soil, from Canada to Virginia; flowers in July.

[Synonyms—*Xylosteum canadense* (Loddiges); *Xylosteum ciliatum* (Pursh).]

Section II.—Chamaecerasi, or False Cherry-fruited Honeysuckles.

These form erect, bushy shrubs, with berries usually connate or joined at the base, and short, axillary, funnel-shaped flowers in twos, which are mostly equal at the base, on slightly gibbose on one side.

Tartarian Honeysuckle (*L. tatarica*).—This is a robust, deciduous, erect, quite smooth shrub from 6 ft. to 8 ft. high; the leaves are rather large, cordate, ovate, and hardly pointed; the peduncles are axillary and shorter than the leaves; the flowers are rose-coloured, short, in pairs, and somewhat gibbose at the base; bracts linear and bristly; the berries are distinct and nearly globose when young, but joined at the base when fully matured, and bright red in the common form when ripe. It is a native of Tartary and Siberia, and flowers in April and May; it is apt to get its young growth cut by the spring frosts, as the plant commences growing very early in the season. There are the following varieties of this species; one with white flowers (*albiflora*), another with beautiful crimson flowers (*rubriflora* or *panicea*), and a third with yellow berries (*lutea*). *L. panicea* is reproduced true from seed, and is considered by most writers as a distinct species.

Hispid Honeysuckle (*L. hispida*).—This is a small, upright, deciduous shrub, 2 ft. or 3 ft. high, with opposite, brownish, hispid branches; the leaves are ovate, ciliated, and from 1½ in. to 2 in. long, and 1 in. broad, very smooth on both sides and cordate at the base; peduncles two-flowered, with ovate-elliptic bracts; the flowers are greenish-white and pendulous; the berries are distinct and purple. It is a native of Siberia on the Altaian Mountains; flowers in May and June.

[Synonym—*Xylosteum altaicum* of Loddiges, and easily distinguished by its brownish bristly shoots and glabrous leaves.]

Blue-berried Honeysuckle (*L. coralea*).—This is an erect, low, deciduous shrub, 3 ft. or 4 ft. high, with the bark of the young shoots of a purple colour; the leaves are oval-oblong, ciliated, stiffish, and clothed with pubescence when young; the peduncles are short and two-flowered; the bracts are in twos and awl-shaped; the tube of the corolla is generally yellow, short, smooth on one side at the base, with the lobes short and nearly equal; the berries are elliptic or globose, dark blue and close joined in one. It is a native of the woods of British North America, in Labrador, Newfoundland, Hudson's Bay, and the State of New York, and flowers in March and April; it is also found in Siberia, France and Austria, and there is no perceptible difference between the American and European plants.

[Synonyms—*Xylosteum villosum* and *Lonicera villosa* (Michaux); *Lonicera velutina* (De Candolle); *Lonicera canadensis* and *altaica* (Pallas); *Lonicera Pallasii* (Professor Ledebour).]

Small-leaved Honeysuckle (*L. microphylla*).—This form resembles the *L. Alpigena*, and is sometimes called *L. montana*. It is a small, erect, deciduous shrub, 3 ft. or 4 ft. high; the leaves are small, elliptic, acute at both ends, rather villous on both surfaces, sometimes rounded at the base and glaucous beneath; the peduncles are two-flowered and shorter than the leaves; the flowers are greenish-yellow; the berries joined, and of a reddish orange colour. It is a native of Eastern Siberia; flowers in April and May.

Webb's Honeysuckle (*L. Webbiana*).—This forms a deciduous, erect shrub, 3 ft. or 4 ft. high, the leaves of which are ovate-oblong, acuminate, obtuse at the base, on very short footstalks, pilose along the nerves, and ciliated on the margins; the peduncles are two-flowered and three times shorter than the leaves; berries half united and black. This is a native of Sirinagur in the East Indies; flowers in April and May. It resembles the *Lonicera Alpigena*, but differs in the leaves being pilose and ciliated.

Dr. Govan's Honeysuckle (*L. Govaniana*).—This is a dwarf, erect shrub, from 3 ft. to 5 ft. high, the leaves of which are elliptic or lanceolate, acute at both ends, membranous, and glabrous; the stalks are two-flowered, three times longer than the footstalks of the leaves, but shorter than the leaves; bracts linear, with the flowers gibbous at the base, and smaller and shorter than those of the *Lonicera Alpigena*, which the plant greatly resembles; berries joined and black. This kind is a native of the East Indies at Sirmour; flowers in April and May.

Black-berried Honeysuckle (*L. nigra*).—This is an erect, dwarf, deciduous shrub, 3 ft. or 4 ft. high, with oval-oblong or elliptic leaves; peduncles two-flowered, elongated, and shorter than the leaves; the flowers are reddish and pubescent on the outside, but whitish on the inside; the outer bracts are lanceolate, the inner ones quadrifid; the berries are black, globose, and joined together at the base. It is a native of the middle of Europe in subalpine woods, particularly in France and Austria; flowers from March to May. The *Xylosteum campaniflorum* of Loddiges is only a variety of this, with bell-shaped flowers.

Alpine Honeysuckle (*Lonicera Alpigena*).—This kind forms a large, robust, deciduous shrub, from 5 ft. to 8 ft. high, with a whitish aspect, and sometimes called the Cherry Woodbine; the leaves are rather large, oval-lanceolate or elliptic, acute, glabrous or pubescent; on very short petioles, rather ciliated; peduncles two-flowered, and shorter than the leaves; the flowers are gibbous at the base; greenish-yellow, tinged with red or purple; the berries are red, of the appearance and size of unripe wild Cherries. It is a native of the middle and South of Europe in subalpine places; flowers in April and May.

[Synonym—*Xylosteum Alpigenum* (Loddiges), of which *Xylosteum sibiricum* is only a variety which comes into leaf and flowers a week earlier than the species.]

Two-coloured Honeysuckle (*L. discolor*).—A deciduous, free-growing shrub, from 4 ft. to 6 ft. high; the leaves are oblong, acute, smooth, from 2½ in. to 3 in. long and about 1 in. broad; they are rather distant, bright green above, glaucous-white beneath, tapering to the base, and on rather short stalks; the flowers are axillary and are produced in pairs at the joints of the shoots, on long footstalks, pale yellow, or nearly white, tinged at the base with pink; the berries are produced singly on long fruitstalks, quite smooth and black, and as large as those of the wild Cherry. This is a very distinct species, which is very attractive in October, when its large, black berries are ripe. It is native of the northern parts of India; flowers in June.

Oblong-leaved Honeysuckle (*L. oblongifolia*).—This is a low, deciduous, erect shrub, and shows well in the front of a flower border; it grows 3 or 4 ft. high, with oblong or oval leaves, clothed with a velvety pubescence beneath; the peduncles are elongated and erect; bracts hardly perceptible; the tubes of the flowers are hairy, gibbous at the base on one side, unequally and deeply lipped, the upper one four-toothed and the lower one nearly entire, and of a yellow colour; the berries are joined in one, bluish-black, and the size of a Pea. It is a native of North America, in the Island of Montreal, the St. Lawrence, Lake Winnipeg, and the western parts of New York; flowers in April and May.

Pyrenean Honeysuckle (*L. pyrenaica*).—An erect, deciduous shrub, 4 ft. or 5 ft. high, with obovate-lanceolate, acute leaves, glaucous beneath; the peduncles are two-flowered and shorter than the leaves; bracts oblong-linear and leafy; the flowers are nearly regular, funnel-shaped, with flat, fine cleft, equal obtuse segments nearly double the size of those of the Fly Honeysuckle, and of a white colour; the berries are globular, distinct, and white. It is a native of the Pyrenees on calcareous rocks in exposed situations; flowers in May.

Involucrated Honeysuckle (*L. involucrata*).—This is a low, erect, deciduous, shrub 2 ft. or 3 ft. high, with acutely, four-sided branchlets; the leaves are large, ovate or oval, petiolate, membranous, and beset with adpressed hairs beneath, and smooth and shining above; the peduncles are axillary and two or three-flowered, the two outer bracts ovate and the two inner ones broad, obovate and clothed with granular pubescence; the flowers are curved, pubescent, gibbous at the base on the outside, and yellow, tinged with red. It is a native of North-west America, and the Rocky Mountains; flowers in May.

[Synonyms—*Xylosteum involucratum* (Dr. Franklin's Journal); *X. Solouis* (Loddiges).]

Dr. Ledebour's Honeysuckle (*L. Ledebourii*).—Robust, spreading, low-branched, deciduous, 2 ft. or 3 ft. high, with

elongated, acutely, four-sided branchlets; the leaves are oval or oblong, somewhat pointed, stiff, pubescent, and tomentose beneath, smooth above, and produced early in the season; peduncles axillary and two or three-flowered, the two outer bracts ovate and the two inner broad, obovate, and pubescent; the flowers are gibbous at the base on the outside, pale yellow, tinged with red and curved; the berries are distinct and dark purple. It is a native of California; flowers in May and June. This kind very much resembles *L. involucrata*, but is a more spreading and freer-growing plant; it has also smaller and yellower flowers.

Oriental Honeysuckle (*L. orientalis*).—The Iberian Cherry-fruited Honeysuckle forms a deciduous, erect shrub, from 3 ft. to 5 ft. high, with ovate-lanceolate, acute, quite entire, and smoothish leaves; they are on very short stalks, stiffish, and larger than those of the blue-fruited one; the peduncles are two-flowered and shorter than the leaves; the two bracts bristly; the flowers greenish-yellow; the berries are joined in one, black or dark blue. It is a native of Iberia and Asia Minor; flowers in April and May.

[Synonym—*Lonicera caucasica* (Pallas in his "Flora Russica"), and frequently confounded with *Lonicera coerulea*, but the leaves are much larger, and the plant is more robust.]

Narrow-leaved Honeysuckle (*L. angustifolia*).—A deciduous, erect shrub, with numerous slender, smooth branchlets, and 3 ft. or 4 ft. high; the leaves are oblong-lanceolate, acuminate, pale and glaucous beneath; peduncles two-flowered, and a little shorter than the leaves; bracts linear, and twice the length of the ovary; berries joined together completely; corolla nearly equal, and pubescent on the outside. It is a native of Nepal and Kanton; flowers in June and July.

Lance-leaved Honeysuckle (*L. lanceolata*).—This desirable and hardy shrub for the flower garden is a spreading, deciduous bush, from 4 ft. to 5 ft. high, with slender pubescent shoots, and the stem furnished with fibrous epidermis. The leaves are lanceolate, hairy and acute at the base; they are pubescent above, shining, hairy and glaucous beneath; the peduncles are axillary, short, but longer than the footstalks of the leaves, and like them villous; it has two linear and four-ovate bracts, the latter rounded and shorter than the others; the berries are distinct, smooth, and the size and colour of Black Currants. Native of Nepal; flowers in June and July.

Standish's Honeysuckle (*L. Standishi*).—This is a deciduous, somewhat erect bush, from 4 ft. to 5 ft. high, with light brown warty branches; the leaves are oval, tapering to both ends, on very short footstalks, feathery nerved beneath, from 2 in. to 2½ in. long, and 1 in. broad, hairy when young, smooth on the upper surface when fully matured, and thinly furnished beneath and on mid-rib with longish hairs, coarsely ciliated on the margins, and of a dull green colour on both surfaces; the flowers are white, rather small, in axillary pairs, and produced in January and February, just before the young leaves begin to appear. The berries are nearly stalkless, in pairs, united at the base, bluish, and on hairy footstalks; they are about the size of a Pea, and enclosed by two long, narrow bracts. It is a native of the North of China, and as it has never been described in any botanical work, has been grown in gardens under the names of *Fortunei* and *præcox*, and sometimes as *longifolia*.

Section III.—*Caprifolium-like Honeysuckle.*

This kind has the robust climbing habit of the Woodbine, and the short, axillary flowers of the Honeysuckle.

Very Fragrant Honeysuckle (*Lonicera fragrantissima*).—This very distinct species forms a robust, sub-evergreen climbing plant, with long brownish leading shoots, and the aspect of a *Caprifolium* in growth. The leaves are broadly-oval, a little pointed, rounded at the base, of a deep shining green on the upper surface, pale or slightly glaucous beneath, quite smooth on both surfaces, with the old leaves retained more or less on the plant all the winter, and the young growth very early, from which the flowers arise; the flowers are white, slightly tinged with pink towards the base, remarkably fragrant, and produced in the axils of the leaves in pairs, on long footstalks, enclosed at the base by two long, narrow bracts; the berries are united at the base, quite smooth, and about the size of a Pea. This is a very desirable plant, on account of its delicious fragrance, which, like the Chinese Allspice (*Chimonanthus fragrans*), produces its flowers during the winter and spring months, when trained against a south wall. The *Lonicera fragrantissima* flowers more abundantly when the ends of the leading shoots are shortened during the summer, so as to cause the plant to make lateral shoots. It is a native of the north of China; flowers from January to March. Fortune found it scrambling among thickets like the common Woodbine.

CALIFORNIAN MANNA.

The "Druggists' Circular" has received from a Californian correspondent some cuttings of Cedar and Pine, covered with saccharine matter which old Californians call "honey-dew," and which is only found in quantities in extremely dry seasons, when the trees are said to be literally covered with it. The specimens were submitted to Prof. Thurber, who furnished the following notes respecting them: "They consist of terminal twigs of two Conifers: a Pine of the section with ternate leaves (three in a cluster or sheath), but which cannot be accurately identified without the cone; and the Californian White Cedar (*Libocedrus decurrens*). Specimens of both are freely incrustated in a stalactitic manner with a nearly pure white substance. A friend who stood by as I opened the box at once declared them to be fragments of a Christmas tree. The taste recalls that of Manna, and if a fragment he carefully separated that is not in direct contact with the stem or leaf, it is free from any terebinthinate flavour. It is one of the numerous saccharine exudations classed under the head of Manna, to indicate a common method of production, rather than identity of chemical characters. "While the Manna of commerce is furnished by a species of Ash (*Fraxinus Ornus*), similar exudations, more or less valued in the countries where they occur, are produced by trees of widely different families. The Leguminosæ and Rosacæ contain Manna-bearing plants; a Tamarisk, a Cistus, a Willow, and one or more Oaks, afford similar products; even the genus *Eucalyptus*, of which so much is now expected, has a Manna-yielding species; with all these very dissimilar plants producing sugary exudations, it is not surprising that we should find them in a family where they would be least expected, judging from its ordinary 'naval store' products—the Coniferae or Pine family. "Manna from Conifers is, however, no recent thing. The Briançon Manna, employed in France early in the last century, is from a Conifer, the European Larch (*Larix europæa*), and received its name from being collected in the mountains about Briançon, where it is still gathered by the peasants for their own use, though no longer in commerce. It is found in mid-summer adhering to the leaves of the Larch, and is collected early in the day, as it disappears with the heat of the sun. Old writers mention the Manna of Lebanon, which some say was afforded by the Cedar of Lebanon (*Cedrus Libani*), but others assert that it was only a synonym for gum mastic. "One of the finest Pines of that country of magnificent trees, our Pacific coast, is known to cultivators as Lambert's Pine (*Pinus Lambertiana*); this reaches the height of 200 ft. and even 300 ft., and is useful as well as grand, its wood serving there for all the purposes that the White Pine does with us. Ordinarily this tree exudes only turpentine, and but little of that; but when the tree is injured by being partially burned, it yields a saccharine substance, formerly used by the settlers for sweetening their food, on which account the tree is known all along the coast as the "Sugar Pine." The Pine, however, among the specimens in question, is not the Sugar Pine (*P. Lambertiana*), as that species belongs to the section having five leaves in a sheath, and shows that there are at least two species of our far Western Pines which produce a Manna. The observation as to its production by *Libocedrus* is, so far as I am aware, quite new, and adds one more to the Manna-yielding genera. As to the cause of this exudation, so long as the phenomenon in the Manna Ash, where there has been abundant opportunity for study and observation, remains unexplained, it is hardly worth while to conjecture in the present case, in which we have only the results. Manna is exuded from this Ash spontaneously, the tree being wounded merely to increase the product. It only occurs in warm and dry countries, and is greatly affected by the character of the season. We have in the specimens, and also in the sugar produced by the Sugar Pine, not only an exudation, but one very unlike that usually yielded by the tree. The ordinary exudation from these trees, in common with others of the Pine family, is turpentine, an oleo-resin. In these cases the character of the exudation is entirely changed, and we have a form of sugar, belonging to an entirely different class of principles. In the Sugar Pine this appears to be effected by destroying the vitality of the tree by partial burning; in the specimens before us it is ascribed to extreme drought."

Gardening as an Industry.—It is strange that fruit and vegetable gardening should not receive among us that attention as an industry which it deserves. We pay £6,000,000 sterling every year for imported fruits alone. France, Jersey, Holland, Spain, and Portugal send us Grapes, Melons, and Figs; we receive enormous quantities of Apples from France and America, and Pears from France and the Channel Islands. So satisfactory to fruit growers are the prices now realised in our markets, that news reaches us from the Continent of fruit culture being rapidly extended in many districts. For some kinds of fruit our growers have but a poor chance in com-

peting with their Continental rivals, but for others the British grower has many advantages, and might develop a very profitable industry. We import, for example, Apples and other hardy fruits at a yearly cost of nearly £2,000,000, and all the time we have thousands of acres of cultivated land devoted to a far less remunerative purpose—timber growing—besides thousands of acres lying waste. As it is, the demand for fruit and vegetables exceeds the supply, and this demand, it is worth observing, arises in a great measure from a growing taste for these articles of food among the more intelligent of our labouring population, who, after all, influence the sale of food commodities far more than the wealthier classes.—F. W. B.

BOMBYX PROCESSIONEA.

THE accompanying woodcut represents the larvæ of a species of *Bombyx* which is very common and does much mischief in woods and pleasure grounds on the Continent, but which happily has not yet found its way into Britain. Those of us, however, who take an occasional run to the Continent (and

Larvæ of *Bombyx processionea* and Beetle which feeds on them.

who now-a-days does not?) must have observed it if their occasions have at all carried them into the woods and plantations abroad. It is called *Bombyx processionea* from its caterpillars being found in flocks, and under certain circumstances walking, as it were, in procession. The eggs are laid at the end of August in little heaps on the bark of the Oak tree, and are not hatched until the following May. The larvæ on coming out form a family of 700 and 800, which keep all together until they become moths. They spin a net in which they live, but in their younger state the net is slight, and they often leave it and spin another elsewhere; at each change of skin, too, they desert their nest to make another. When they have changed for the last time they make a much larger dwelling-place, which is usually $1\frac{1}{2}$ ft. in length by $\frac{1}{2}$ ft. broad, of no particular form, but rounded at both ends, and attached vertically to the trunk of the tree, often quite close to the ground, at other times 6 ft. or 7 ft. up. These nests look like excrescences or nodosities on the part of the bark where they are formed, and at the top of this silken bag there is an opening by which the caterpillars pass out and in as they like. When these caterpillars quit their lodging to go and establish themselves elsewhere, their march is conducted in regular order. When they set out one caterpillar goes first and heads the column, the rest follow in files like a string. The first is always single, the

rest are sometimes two or three in a line, and they keep their line so exactly that the head of one never passes that of its neighbour. When the leader stops, the rest stop too, and wait until it resumes its march. This is the order in which they are most frequently seen in procession crossing the alleys of woods, or passing from one tree to another, which they do whenever they find the tree on which they are situated insufficient for their sustenance. It is towards sunset that the caterpillars usually perform their promenades, and it is only during the night that they devour the leaves. They may sometimes, however, be found in full day basking in detachments or little clusters on the bark of the trees not far from their habitations; they are, however, so like the bark in colour and appearance that they may be easily overlooked. When the time for passing into the chrysalis arrives, they each spin a separate cocoon inside the general nest, in which they may undergo their metamorphosis, and if, as sometimes happens, the general nest is insufficient to contain the whole of the cocoons, they spin an addition to the house, or make a new one, alongside the first. The nests, especially the old broken ones from which the moths have emerged, should not be touched with the naked hands, for the hairs and broken remains of the insects produce frightful itching, and sometimes severe inflammation of the hands and face, or any other part where the skin has been exposed to them. Baths and acidulated lotions, however, soon cause these unpleasant symptoms to disappear. As in other insects, the number of these processional caterpillars varies in different years. Sometimes they have occurred in great numbers, so much so that even in the Bois de Boulogne certain parts of the wood have had to be closed to the public on this account. The plan adopted for getting rid of this insect is to rake off the nests from the trees and burn them. It should be done in the month of July, and in wet weather, when the larvæ are all at home sheltering from the rain. The moth is small for a Bombyx, of a greyish-white colour, with dark brownish bands across the upper wings. The insect is found over almost the whole of Europe.

The beetle figured alongside the larvæ is the *Calosoma sycophanta*, which makes great havoc among them, and has a special liking for feeding on them. A. M.

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE FLOWER SHOW.

MAY 12.

This exhibition was on the whole a very successful one; the chief attraction was the Roses in pots, but Orchids were also fairly well represented. The practice, however, of making up specimens for purposes of exhibition by crowding numbers of small plants closely together in one large pot or pan is much to be deprecated; evidences of it were but too apparent on this occasion. New plants were sparingly exhibited, and in nearly every case those which received certificates had been similarly distinguished on previous occasions.

Stove and Greenhouse Plants—These were, taken altogether, well represented, but there is a sameness about such exhibitions nowadays that considerably diminishes their interest. Messrs. Jackson & Sons, Kingston, had the best group of twelve plants to which, however, a second prize only was awarded. In this group the most distinct plants were *Rhododendrons* Princess Alice, having large fragrant white blossoms; *Statiea profusa*, a mass of purplish-blue flowers; *Aphelaxis macrantha purpurea*; and *Hedaroma fuchsoides*, in excellent condition; as was also the orange-flowered Cape Lily, *Imantophyllum miniatum*, bearing eighteen trusses of rich orange-yellow flowers. *Baronia pinnata*, and one or two well-grown heaths were also included in this group. In the class of nine specimens Mr. Chapman sent a well-arranged group, consisting of *Anthurium Scherzerianum*, a white Cape Heath, *Chorozema Chandleri* (a mass of orange flowers), together with *Pimelea mirabilis*, *Dracophyllum gracile*, a good *Ixora*, and *Erica depressa*, the latter remarkably well bloomed. Mr. B. Peed, who was second, had *Franciscea calycina*, *Imantophyllum miniatum* (bearing from twenty to thirty trusses of bloom), *Clerodendron Balfourii*, *Epacris Eclipse*, the yellow-flowered *Erica Cavendishi*, and others equally good. Mr. Tudgey also showed a well-grown collection in this class, and the same exhibitor was likewise first in the class of six plants with *Ixora Williamsi*, *Erica ventricosa* magnifica studded with clusters of carmine-tipped flowers, and a well-bloomed *Hedaroma tulipiferum* 5 ft. through: Mr. Chapman was second. Mr. Bristow, who exhibited a group in the same class, had one of the best-flowered little plants of *Vanda suavis* we ever saw, a fresh and healthy single break, 2 ft. in height, bearing three stout spikes, two of which bore twelve or thirteen fully-expanded flowers respectively. Heaths

were represented by a well-grown group from Messrs. Jackson, in which *Erica Cavendishi*, *ampullacea*, *oblata*, *depressa*, &c., were conspicuous. Other sorts were *E. coccinea minor*, 2 ft. 6 in. in diameter, and nicely bloomed; *elegans*, 4 ft. through; and others of similar proportions. With the exception of the Roses, the most brilliant and attractive plants in the exhibition were the Azaleas, the principal exhibitors of which were Mr. A. Ratty and Mr. Charles Turner. Messrs. Rollisson & Sons also showed good plants. Mr. Ratty had well bloomed plants of *Model Rose*, *Georgiana*, *scarlet*; *Eulalie Van Geert*, white and rose; *Mrs. Fry*, *carmine*; and *Criterion*. Mr. James Child had *Iveryana*, white, 5 ft. in height; *Reine des Belges*, semi-double rose; *Barclayana*, white; *Rosea elegans*, *vermilion*; *arboorea purpurea*, purple; and *Duchess Adelaide de Nassau*, *vermilion* flushed with purple. In the class of twenty plants Mr. Turner was first with a remarkably even and well-flowered collection, consisting of plants about 2 ft. in height, which are far more useful and attractive than more unwieldy specimens. Among these we noted *Duc de Nassau*, *carmine*; *Mrs. Turner*, *salmon-rose*; *Verschaffelti*, *vermilion*; *Souvenir de Prince Albert*, semi-double rose edged with white; *Neptune*, *scarlet*; and others. Mr. A. Ratty, who was second with equally well-bloomed but more irregular plants, had good examples of *Flag of Truce*, double white; *La Superbe*, *scarlet*; *Bernhard André*, a semi-double rosy variety; and others. Mr. C. Turner was awarded an extra prize for nine well-grown specimens, among which we noted *Cedo Nulli*, purple; *Reine des Fleurs*, *salmon-rose* and white; *Comtesse de Flandres*, *crisped rosy-lilac*; and *Madame Verschaffelt*, *salmon* with white-edged *crisped petals*—one of the most distinct.

Fine-foliaged Plants—The best *Crotons* came from Mr. John Wills, who had pretty little specimens of *C. undulatum*, *C. multicolor*, *C. Youngi*, *C. ovalifolium*, and others. Mr. Ley, Croydon, had, however, better-coloured plants, but they were somewhat irregular in size and quality; among these the most distinct were *C. undulatum*, *C. trilobum*, and its small, golden-margined form named *hastilobum*, together with a small plant of the bright golden-netted *C. Wiesmanni*, and others. Amongst the Palms, which were well represented, Mr. Ley had the best group, in which there was a unique specimen of the graceful fan-leaved *Chamærops tomentosa*, the slender, radiating segments of the leaves being covered below with silvery tomentum. *Geonoma Schottiana*, an elegant pinnate-leaved species, was also in this collection, as were likewise *Euterpe edulis*, and a splendid young plant of the stately, fan-leaved *Pritchardia pacifica*. Mr. Legg's group, which was a good one, included the formidably-armed *Dæmonorops peracanthus* and the graceful *D. palmbanicus*, together with one of the best plants which we have yet seen of the fresh green, glossy-leaved *Martinezia granatensis*, in addition to *Cocos Weddelliana* and a plant of the broad, fan-like *Verschaffeltia splendida*. In a miscellaneous group contributed by Mr. Ley, we noted several plants of a most distinct Palm named *Chamedora elegantissima*, the slender, wand-like petioles of which attain a height of from 8 ft. to 10 ft., arching gracefully, the slender grassy pinnæ hanging from the upper side in the most pleasing manner; indeed, this Palm is so distinct in habit that it well deserves a place in the most select collection of fine-leaved plants. The best collection of Ferns was shown by Mr. B. S. Williams, who had several good plants of *Gleichenias*, including *G. dicarpa*, 3 ft. in diameter; *G. Spelunca*, rather larger; and *G. rupestris*, together with good examples of *Adiantum Farleyense*, *Asplenium Nidus Avis*, *Cibotium Scheidei*; and the stately black-striped *Cyathea medullaris*, with an ample coronal of feathery fronds. Mr. E. Tudgey sent a beautiful plant of *Onychium japonicum*, 4 ft. through, the fronds being of a rich, dark glossy green tint, like that of some *Trichomanes*. This is one of the most elegant and distinct of all decorative Ferns, and one but too rarely met with in gardens. Other plants in this group were *Adiantum Farleyense*; *Gleichenia Mendeli*, 3 ft. in diameter; *G. flabellata*, and an example of *Gymnogramma decomposita*. Mr. Peed and others had also good collections. Mr. T. N. Penfold, gardener to Rev. Canon Bridges, Beddington House, Beddington, furnished twelve well-grown Ferns in this class, including a pretty little plant of *Dicksonia squarrosa*, *Platynerium grande*, *Todea superba*, and *Trichomanes radicans concinna*. In the class of twelve fine-leaved plants, Mr. Legg had an excellent selection, consisting of remarkable examples of *Dasyliroton acrotichum*, *Croton Johannis*; *Davallia Mooreana*, a fresh, feathery mass of light green fronds, 7 ft. in diameter; *Alcacia Lewi*, with great bronzy shield-shaped leaves; a superb plant of the gold-veined *Croton Wiesmanni*, 7 ft. in height; and good examples of *C. angustifolium*, still, when well grown, one of the finest of all *Crotons*. Mr. Tudgey had also a good group, in which *Pritchardia pacifica*, *Dasyliroton acrotichum*, and a splendid plant of *Cordylone indivisa* were the most noteworthy. Mr. Ley's group was a good one, but owing to its distance from others, it appeared to have escaped the attention which it deserved. Among other plants in it we noted *Yucca filamentosa variegata*, *Cocos Weddelliana*, *Phœnicophorium Seychellarum*, *Cycas revoluta*, *Yucca aloifolia variegata*, *Pandanus Veitchi*, *Marantas*, &c. Mr. Legg was first in a class of eight fine-leaved plants, Mr. Ford being second with a prettily-arranged collection, in which the plicate-leaved *Pennisetum fimbriatum*, a tall ornate Grass, and a gigantic Aroid (*Caladium nymphaefolium*), were the most noticeable, the great shield-shaped leaves of the latter being of a dark velvety green colour, and their dimensions about 4 ft. long and 3 ft. broad, each being elevated on smooth, cylindrical petioles, 4 ft. or 5 ft. in height. A plant of the velvety-leaved *Cissus discolor* was also very finely coloured. Mr. J. Wills showed an attractive group in Class I, including *Yucca filamentosa variegata*, 4 ft. in diameter; *Pritchardia Martynia*, a distinct fan-leaved Palm; the purple-leaved Bread-fruit (*Artocarpus Cannoni*); and the silvery-veined *Anthurium crystallinum*, all in excellent condition. Mr. Wills also contributed a large group of his new seedling *Dracænas*

tastefully arranged, and small Palms, margined with a line of fresh green Maiden-hair Fern. Among the kinds shown the most noticeable were D. Willsi, a dwarf, robust habitated plant, with broad, recurved, bronzy-purple leaves, margined very regularly with carmine; D. terminalis alba, one of the best white-striped sorts; D. Mrs. Wills and D. Mrs. Bausé, all exceedingly effective kinds. Mr. J. H. Ley showed a miscellaneous group of Palms, new Ferns, and other fine foliated plants in excellent condition. Messrs. F. & A. Smith, Dulwich, had also a large and well-arranged group of Palms, Ferns, stove and greenhouse plants, and florists' flowers. Messrs. J. Laing & Co., Forest Hill, sent a large and varied group of Crotons, Palms, Ferns, and Cycads, together with Caladiums, Dracenas, Marantas, and other stove plants, all effectively and tastefully arranged. Messrs. Rollisson & Sons, Tooting, showed a very interesting miscellaneous collection of Palms, Ferns, succulents, and other decorative plants, including good specimens of Echeveria azaroides, E. Peacockii, E. pulverulenta, a mealy Californian species, and one of the most distinct in the whole group. In this group we also noted a distinct and fresh green pinnate-leaved Palm, named Calamus schizospathus, having spinose petioles, and four or five broad leaflets, arranged in a sub-peltate manner at their apices. Mr. James Ford, gardener to J. G. Megaw, Esq., Windermere House, Norwood, showed a large and well-arranged group of Ferns, Orchids, Begonias, and other decorative plants in good condition. Fine-leaved plants in small pots, intended for room or dinner-table ornament, were represented by several good collections, the best being sent by Mr. Lambert, who had pretty little plants of Croton angustifolium, Pandanus Veitchii, Demonorops pulembanici, the slender-leaved Dracena gracilis, Cocos Weddelliana, and the still more elegant Geonoma gracilis. Mr. Wills, who was second, had Staudmannia scorbifolia, with bright green pinnate foliage; Croton Disraeli, well coloured; Aralia elegantissima; Dracena Percy, crimson-striped; D. Victoria, white-striped; and the graceful Chameleroia formosa. Mr. Bristow, Dulwich, had Adiantum gracillimum; Pandanus Veitchii; Croton Wismannii; Aralia quinquefolia, very distinct and excellent for table; Cocos Weddelliana; Cassurina Sumatrana, a perfect plant, but too large and dense for table work. Messrs. Rollisson & Sons had Reidia glaucescens, Dracena Guilfoylei, D. gracilis, Geonoma gracilis, Aralia Guilfoylei, and Dracena terminalis.

Orchids.—In the class of ten exotic Orchids, Mr. B. S. Williams was first with well-grown and floriferous plants, among which we noted the snowy-white *Cypripedium novium*, bearing twenty-five flowers; *Oncidium sacodes*, with three or four good spikes; a splendid variety of the *Pescotara Odontoglossum*, the most elaste species in the whole genus, bearing two branched spikes, on which there were about fifty large flowers. Associated with these were *Sobralia macrantha* named *Woolleyi*, bearing seven flowers; *Cypripedium villosum*, with sixteen or more of its brownish glossy flowers; *Cattleya Mossie*, named *grandiflora*, bearing five delicately-tinted blossoms; a good plant of *Cypripedium barbatum* bearing twenty-six flowers, the upper part of the dorsal sepal being pure white veined with purple. A floriferous plant of the golden *Oncidium Marshallianum*, bearing five spikes, brightened up this collection, which contained moreover two plants of *Vanda tricolor*. Messrs. Jackson & Son were second with smaller plants, among which was a superb example of the true old *Odontoglossum citrosum* roseum, bearing four strong spikes, the waxy flowers being of a delicate flesh colour, and having a clear, bright, rosy lip, fully as bright in colour as the oft-mentioned figure of this variety in Warner's "Orchidaceous Plants." It also contained good plants of the *Odontoglossum Alexandræ*; a mixed pair of the Bearded *Cypripedium*, bearing the name of *C. barbatum superbum*, one or two of the varieties, however, being about the worst we ever saw exhibited; a plant of *Vanda tricolor formosa*, with four or five good spikes of richly-tinted flowers; *Saccolabium retusum*, with three well-developed spikes; a floriferous plant of *Masdevallia Lindenii*, and *Cypripedium hirsutissimum*, and *Cattleya Mossie superba*, the last a richly-tinted form, bearing twelve flowers. In the amateurs' class of eight Orchids Mr. James Child was first with excellent specimens, among which we noted the following:—*Dendrobium Farmeri*, a delicate variety, bearing three gracefully-drooping thyrse-like clusters of rosy flowers; also a good plant of *D. crystallinum* bearing four or five good spikes. Associated with these was also a good *bona fide* specimen of the true *Dendrobium barbatum superbum*, bearing twelve very large and highly-coloured flowers, and, perhaps, one of the finest examples of *Oncidium ampliatum majus* ever exhibited, a mass of enormous plump pseudo-bulbs and fresh green leathery leaves fully a yard in diameter, bearing thirteen branched spikes, each from 3 ft. to 4 ft. in height. As shown by Mr. Child this is certainly an attractive and desirable species for exhibition, and all the more creditable since even respectable examples of it are but rarely met with in even the best collections. Another good and well-grown old plant in this group was *Camarotis purpurea*, bearing twenty or thirty spikes of rosy-purple flowers. Mr. B. Peed had a well-grown group, also including a small but healthy plant of *Oncidium ampliatum majus*, bearing three good spikes; *Phalænopsis amabilis*, with twelve flowers. Here, again, we noticed a made-up pair of mixed varieties of *Cypripedium barbatum*.

Roses in Pots.—These were well represented, although perhaps not in the full glow of floral beauty as seen at the corresponding exhibition last season. Mr. Charles Turner had, however, well-bloomed specimens, varying from 5 ft. to 6 ft. in diameter, and of about the same height; Messrs. Paul & Sons showed still larger specimens, and in admirable condition, but not so perfect as regards floral beauty as usual, indeed, a sunny day or two would have improved them immensely; as it was, however, Mr. Turner obtained first prizes with examples of *Madame T. Levet*, a rosy variety; *Duke of Edinburgh*, crimson; *Charles Lawson*, rose; *La France*, one of the most beautiful and popular of all modern varieties,

having revolute petals of a soft, satin-like, rosy tint; *Maréchal Vaillant*, a crimson variety, was also in good condition, and contrasted well with the rosy-tinted *Juno*, another old favourite, and in this case superbly flowered; *Victor Verdier* is a variety one looks for as a matter of course, and in this case its bright rosy-crimson bloom is told with good effect, being contrasted with a plant of the soft rosy *Anna Alexieff* in splendid condition, the whole group being brightened up by a specimen of *Celine Forrester*, 5 ft. or more in diameter, and a mass of waxy foliage and bright sulphur-yellow flowers. Messrs. Paul & Son, Cheshunt, who were second, had large, well-furnished plants, but these, too, were a day or two behind as regards floral development. Among them we remarked a superb example of *Celine Forrester*, perhaps 6 ft. or more in diameter, but scarcely in bloom; *Dr. Andry*, a glowing crimson variety, with bold, dark foliage; and *Victor Verdier*, in excellent condition; as were also *Anna Alexieff* and the soft rosy *Princess Mary of Cambridge*, one of the best of all light roses for culture in pots; *Horace Vernet* and *Madame V. Verdier* were well furnished with bloom, as were also *John Hopper* and a specimen of *Madame de St. Joseph*—the latter was simply superb; it is, as most people know, a Tea-scented variety, which bears globular, smooth petalled, salmon-tinted flowers, and, like *Souvenir d'un Ami*, is always welcome as a distinct and effective plant in a collection. In the class of twenty Roses in pots, Mr. Charles Turner, who was the only exhibitor, had a beautiful group. Here we noted the new *H. P. Annie Laxton*, evidently a first-rate variety, having large, full, rosy flowers; and *La France*, bearing splendid blossoms; *Rev. J. B. M. Cunn*, bright crimson; *Marie Van Houtte*, with glossy foliage and delicate sulphur-tinted flowers; *Miss Hussard*, another variety, evidently most noticeable as a pot-plant, bearing large full flowers of a silvery-rose colour, a shade or two darker than that of *La France*. The rich, rosy-crimson *Marie Bannmann*, and the salmon-tinted *Souvenir d'un Ami* were also well represented. In the amateurs' class, Mr. J. W. Moorman carried off the premier award with six well-grown plants, among which we noted *Annie Laxton Rose*, *Victor Verdier*, the creamy flesh-tinted *Madame Villermoz*, and one or two others. Mr. W. Phillips, Youngsbury, had a group consisting mostly of Tea-scented varieties. In the miscellaneous class Mr. W. Paul had an effective and well-grown group of Roses in pots, including some of the best varieties, and also six large stands of cut blooms in splendid condition. Mr. Copp, Oxford, sent several superb stands of the soft, golden-coloured *Maréchal Niel*. Messrs. Paul & Son, Cheshunt, showed six stands of cut Roses, among which we noted very fine flowers of *La France*, *Maréchal Niel*, *Niphetos* (one of the sweetest of all Tea-scented varieties), *Gloire de Dijon*, and others.

Florists' Flowers.—Show and French *Pelargoniums* were furnished by Mr. Charles Turner and Mr. James, of Isleworth, both of whom had excellent collections. Among the show kinds sent by Mr. Turner we noticed good plants of *Scottish Chieftain*, crimson and black; *Duchess de Morny*, pink or flesh and white with a dark spot; *Mail of Honour*, a large, smooth, flesh-coloured flower, having a dark blotch on the upper petals; *Claribel*, white with rosy spot; and *Digby Grand*, an elegantly crisp kind of the *Dr. Andry* type. In the fancy class Mr. Turner had *Princess of Teck*, white, rosy blotch; *East Lynne*; *Excelsior*, bright carmine, white eye; *Jubot*, maroon-crimson, and white, rosy spot; *Henry Baily*, carmine-maroon, white eye; and *Helen Beck*, all in excellent condition, considering the earliness of the season. Mr. James had among large-flowered kinds, *Sultan*, rose and black; *Princess of Denmark*, white and crimson; *Pompey*, scarlet and black; *Pericles*, flesh, upper petals maroon; *Statesman* and *Snowflake*, the latter white with a purple spot. Among fancy varieties Mr. James had *East Lynne*, dark carmine and white; *Roi des Fantaisies*, carmine and white, with rosy-spotted lower petals; *Princess of Teck*, white and rose; *Ellen Beck*, lilac edged with white, and having a clear white eye. Messrs. F. & A. Smith sent several seedling *Pelargoniums* for certification, including *Perle Blanche*, white, rosy-purple spot; *grandiflorum*, flesh with maroon spot—a large-flowered kind; *Improvement*, a very vivid rosy-scarlet variety of good habit. A plant of a spreading and elegant-habited dark-leaved *Zinnia* came from the same exhibitor. Mr. James furnished the best *Cinerarias*; they were dwarf yet robust in habit, and the flowers, which were of good form, were arranged in dense masses, vivid and distinct in colour. Mr. J. T. Salter, of Laurie Park, had a good group of herbaceous *Calecolarias*, to which a first prize was awarded; Mr. James had also a collection of compact, well-bloomed specimens. Mr. Edward Shenton, 17, Mansfield Road, sent a group of Alpine and self-coloured *Auriculas* swathed in cotton wool, which entirely destroyed their beauty. Two stands of fresh and beautiful Alpine *Auriculas* came from Mr. Charles Turner, and the same exhibitor had new *Azileas* and other plants.

Miscellaneous Plants.—Mr. R. Parker, Tooting, showed a large group of hardy flowers in pots, the most effective among them being *Palox Nelsonii*, studded with snow-white flowers; *Cheiranthus Dilleni*, with yellow, pink, and purple-tinted blossoms; *Centaurea montana alba*; and several large pots of pink, lilac, blue, and white *Scillas* of the *S. nutans* and *S. campanulata* types. Mr. H. Hooper, Bath, had a small collection of seedling *Violas* or *Pansies*, and *Daisies* in good condition. Messrs. Rollisson and Mr. Ley furnished good groups of the parti-coloured *Dracenas* now so popular, and in Mr. Ley's collection we especially noted the elegantly recurved, bright green *Dracena lutescens* as being one of the most distinct and effective, the zebra-striped *D. Goldiana* excepted. Mr. Coppin, Shirley, sent a group of *Tricolor Pelargoniums*, a class of plants which may be said to have had their day, inasmuch as they do not seem now to meet with a welcome anywhere. Mr. S. Moyse, 22, Stockbridge Road, Bournemouth, sent two well-arranged bouquets, viz., a bridal one formed of *Bouvardia*, *Eucharis*, *Phalenopsis*, *Tea Roses*, *Orange blossom*, and other white flowers, tastefully garnished with Maiden-hair

Fern; and a ball-room one which was composed of rosy and yellow Roses, Orchids, Bouvardias, Eucharis, and Lily of the Valley, with here and there a sprig of Hoya flowers and spray-like Maiden-hair Fern. Several well-filled Fern cases and glass shades were exhibited by Messrs. Dick Radclyffe & Co., High Holborn, who also had some window-boxes of novel design. Mr. M. Hodgkins, 35, Hyde Grove, Manchester, had a large collection of skeletonized and bleached Fern fronds, and leaves of various kinds including some large Bauhinia, Ficus, and Maple leaves, Poppy-heads, and fruits of *Datura Stramonium*. This collection was one of the most perfect, as regards execution and arrangement, that we have yet seen. Mr. Colbourn, gardener to Burn Blythe, Esq., Woolhampton, Bucks, sent an excellent sample of the fruit of the Japanese Medlar (*Mespilus japonica*); and Mrs. Halstead, Palace Square, Upper Norwood, had a pretty Fern-box formed of virgin Cork, Fir cones, and Oak galls.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

MAY 15.

THIS meeting, though comparatively a small one, was nevertheless one of considerable interest to horticulturists. The Roses in pots sent by Messrs. Veitch were remarkably fresh and perfect, both as regards leafage and bloom, as were also some choice Orchids from Sir T. Lawrence's collection. Mr. Charles Turner showed a fine group of Azaleas, and cut Roses in excellent condition came from Messrs. W. Paul & Son.

First-class Certificates.—These were awarded to the following new and rare plants:—

Dracæna Robinsoniana (Veitch).—A robust-habited variety, from the South Sea Islands, the young leaves of which were of a creamy-white colour suffused and striped with rose.

Azalea mollis Couleur de Paille (Veitch).—A dwarf and floriferous seedling variety, of a soft and pleasing yellow colour, admirably adapted for pot culture and early spring flowering as a greenhouse plant.

Oncidium crispum marginatum (Sir T. Lawrence).—A large-flowered form of *O. crispum* with the colouring of *O. Forbesi*, but with much larger flowers. The largest bloom on this plant was fully 3 in. in diameter, the glossy brown petals and reniform lip being margined with a broad, brown-spotted, yellow band.

Cypripedium occidentale (H. J. Elwes).—A graceful little two-flowered plant, having the habit and flowers of *C. Calceolus*, except that in this case the slipper-shaped lip is pure white instead of yellow. It is a pretty little plant, superior in beauty to *C. candidum*, of which it may possibly prove to be a variety. Lindley describes a similar plant under the name of *C. cordigerum* as being found in Europe, Dahuria, and, according to Thunberg, in Japan, adding, that its characters are those of *C. Calceolus*, with the exception of the white lip.

Miscellaneous Plants.—A remarkably well-grown group of pot Roses, fine-foliaged plants and Ferns came from Messrs. James Veitch & Sons, Chelsea, who also sent three or four new varieties of the Chinese *Azalea mollis*, to one of which allusion has just been made. The new white-flowered *Hydrangea*, Thomas Hogg, was again shown in admirable condition, the colour being whiter, if possible, than before. A new *Dracæna*, named *D. Robinsoniana*, more fully described elsewhere, was very attractive in this group, as was also *D. speciosa*, another distinctly-marked form; also, from the South Sea Islands, *Adiantum æmulum*, a distinct species, even more graceful than *A. cucullatum*, was much admired. Messrs. Veitch & Sons also furnished *Cinnam Makoyanum*, a kind which closely resembles *C. amabile*, having strap-shaped, dark green, glossy leaves, and a tall scape of drooping, Lily-like flowers, of a delicate flesh colour, the buds being bright rose. The group of pot Roses sent by this firm consisted of some thirty or forty plants, amongst which we especially noted a fresh little specimen of *Celine Forrestier*, a delicate sulphur-tinted variety, bearing five or six perfect blooms, reminding one of those of *Niphetos* as regards perfect form and substance of petal; the new white *Madame Laclarme* was also in excellent condition, a small but well-bloomed plant bearing eight finely-shaped flowers; a seven-flowered plant of Captain Christy was as nearly perfect as Roses in pots can be, and there were excellent plants of *La France*, the vivid rosy-crimson Beauty of Waltham, and a plant of *Alba Rosea* bearing six superb flowers, one of which would have graced the most select stand of exhibition blooms; Duke of Edinburgh was set off to advantage among the paler kinds, its flowers being of a vivid crimson-scarlet colour; and a plant of *Paul Neron* was remarkable for its pale, rose-tinted, large flowers. Messrs. Mayo & Co., Corn Market, Oxford, sent a choice group of *Maréchal Niel* Rose-blooms tastefully arranged on beds of green Moss. Mr. Turner, Royal Nurseries, Slough, contributed a large group of half-specimen Azaleas, amongst which were finely-bloomed plants of *Monseigneur Cuvellier*, a variety with rich crimson purple-shaded flowers of good form; *Charles de Back*, with large stiff-petaled blossoms of a bright purple colour; *Mrs. Turner*, a free-growing variety, with flowers possessing a pink ground edged with white, the upper petals being spotted with purplish-crimson. Flag of Truce was the best pure white double-flowered kind. Flambeau is a very effective kind with deep crimson blossoms. Amongst the newer kinds were small plants of *Jean Vervaene*, with flowers of a rich salmon colour, distinctly edged and, in some cases, striped with white. Messrs. Cutbush & Sons, Highgate, exhibited a group of miscellaneous plants consisting of Palms, *Dracænas*, and hard-wooded greenhouse plants, among which we noted *Boronia serrulata*, well covered with lively rosy-purple blossoms, good pans full of the scarlet-flowered *Correa cardinalis*, well-bloomed *Ericas*, and *Genetylis tulipifera*. Sir Trevor Lawrence, of Burford Lodge, Dorking, sent six choice Orchids in the best health and floriferous vigour. These

consisted of a plant of *Odontoglossum citrosimum* roseum, bearing three graceful-drooping spikes of rosy-lipped flowers. A plant of *O. Andersonianum* also bore a branched spike of richly-spotted blossoms, and *O. triumphans* bore a long, twelve-flowered spike of rather pale but shapely flowers; *Oncidium metallicum*, a near relative to *O. diadema*, also bore a long, flexuose spike, of rich brown flowers, the peculiarity of which consists in their fringed points being interlocked so as to form an arch over the column in front of the flower. A strong plant of *Cattleya Schilleriana* bore seven large and richly-coloured blossoms, the olive-green sepals of which are spotted with purple, the broad, fringed, white lip being richly veined with bright carmine. A large-flowered form of what is called *Oncidium Forbesi* in gardens was also included in this group under the rather formidable name of *O. crispum marginatum grandiflorum*. *Houlletia Lowi*, to which a botanical commendation was given, is a large-flowered, sulphur-coloured Orchid, the point of interest about which is its large, three lobed lip having an orange, glossy, horseshoe-shaped disc. Mr. J. Wills, Sussex Place, Old Brompton, sent an attractive group of *Odontoglossums*, *Cypripediums*, and Maiden-hair Fern in admirable condition; *O. Alexandrae*, *O. Pescatorei*, and the rare and beautiful *O. Andersonianum* were included in this group; these kinds being largely grown by M. Wills for decorative purposes. A very pleasing group of new seedling *Clematises* came from Mr. Charles Noble, Bagshot, among which we noted *President*, a large, violet-purple, eight-sepalled flower, 7 in. in diameter; *Undine*, a double-flowered lilac; *Margaret Dunbar*, a shapely, broad-sepalled, lilac form of great beauty; and *Mademoiselle Torraui*, also a very distinct and pleasing form, having pale lilac, eight-sepalled flowers shot with a rosy metallic tint. Messrs. W. Paul & Son, of Waltham Cross, showed six excellent stands of cut Roses, among which we noted *Star of Waltham*, one of the most robust and desirable of all English-raised varieties, also *St. George*, a shapely flower of a rich purplish-crimson colour; *Peach Blossom*, also conspicuous, its globular flowers being of a delicate rosy-carmine tint; *La France*, *Maréchal Niel*, *Devoniensis*, *Paul Neron*, and *Souvenir d'un Ami*. Mr. Ollerhead sent a large flowering branch of *Aristolochia brasiliensis*, bearing three or four great purple-speckled and veined pitcher-like flowers. A stand of cut flowers of *Pelargonium "New Life"* came from Mr. H. Cannell, Swanley, Kent, but the blossoms were less distinctly marked than we have hitherto seen them, having, in fact, a speckled appearance, instead of the clear white stripe which sometimes shows itself. Mr. F. Bell, Lakenham, furnished three examples of *Adiantum Capillus-Veneris corymbiferum*, a crested Maiden-hair, very similar to the *A. Luddeemannianum* exhibited last season by Messrs. Veitch & Sons. Mr. R. Dean, Ealing, showed a group of large-flowered *Mimuli*, the colours of which were very varied and distinct; also a basket of blue bedding Pansies, namely, *Blue King*, a light blue with dark spot; and *Blue Beard*, a darker and richer-tinted variety. With these came *Viola pedata*, having lobed leaves and lilac-blue flowers; *Sempervivum Boissieri*, a compact, reddish-tinted form, with a metallic hue on the green tip of the lance-shaped, ciliated leaves; a pot of the dwarf blue and white-flowered *Veronica repens* was much admired, as were also some velvety *Polyanthuses* and a large mass of *Saxifraga granulata fl.-pl.*, bearing greenish-white flowers. Mr. Elwes, Preston, Gloucester, sent *Tulipa undulatifolia*, a crimson-flowered plant in the way of *T. Eichleri*, but having smaller crimson flowers and narrow, undulated, margined leaves; the margin of yellow around the black spot at the base of each petal is also nearly entirely absent in this plant, which well deserves culture as a distinct and beautiful hardy Tulip; also *Calcocaria crenatifolia*, a clear yellow-flowered plant of slender habit; likewise *Elisena longipetala*, a curious, white *Amarylloid*, having *Paneratium*-like, white flowers, with a deflected, flattened corona.

Fruit and Vegetables.—Mr. Jenks, gardener to D. Larnack, Esq., East Grinstead, Sussex, showed a dish of excellent *Grosse Mignonne* Peaches, stated to have been gathered from a tree bearing 243 fruits. The fruits exhibited were very large and beautifully ripened for this comparatively early time of the year. Mr. Booth, gardener to J. Wright, Esq., showed a collection of seedling Cucumbers, amongst which were fruits of good size and quality, and also an example of the *White American Cucumber*. Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, showed seedling *Melons* of the green and scarlet-fleshed varieties; in both cases the fruit was of good flavour, considering the dull season in which they have been ripened. Mr. Douglas, Loxford Hall, showed a good fruit of *Tender* and *True Cucumber*.

ROYAL BOTANIC SOCIETY'S SHOW.

MAY 16.

THIS exhibition was a large and attractive one, Orchids and fine-foliaged and flowering plants being well represented. Among the exhibits which call for especial notice may be mentioned the bright and attractive group of *Rhododendrons* and yellow Chinese *Azaleas*, fringed with cut-leaved Japanese Maples, and other fine-foliaged plants, shown by Messrs. Veitch & Sons, and the large and well-bloomed specimen Roses furnished by Mr. Charles Turner and Messrs. Paul & Son. Mr. Chapman sent a beautiful sample of the lilac *Bongainvillea glabra*; and in Messrs. Jackson's collection we remarked a large and well-bloomed *Imantophyllum miniatum*, one of the most distinct and effective of flowering plants for purposes of exhibition. Mr. Denning showed a well-grown plant of *Odontoglossum citrosimum*. Mr. Williams had a fresh and floriferous *Vanda snavis*; a well-bloomed *Dendrobium Falcoueri* was sent by Mr. Michaels; and Mr. Child showed a plant of *Aerides Fieldingi* in admirable condition, being four large branched spikes; and also a noble

specimen of *Oncidium ampliatum majus*, elsewhere alluded to. Mr. Legg's fine-foliaged plants were remarkable for their freshness and vigour, his *Cycas revoluta* bearing fifty-four new leaves, being unique, and his plants of *Croton Wismanni* and an eight-leaved Palm (*Stevensonia grandifolia*) were as near perfect as could be desired.

Certificates.—These were awarded to the following new and rare plants:—

Anthurium Browni (Veitch).—An enormous glossy-leaved Aroid already described.

Adiantum Capillus-Veneris corymbiferum (Bell).—A variety of the common British Maiden-hair Fern, very similar to *A. Ludemannianum*.

Clematis Lady Egmont (Jackman).—A large and sepalled variety, having delicate bluish-lilac flowers of good form and substance, admirably suited for pot culture.

Clematis Florence (Jackman).—A delicate lilac-tinted and sepalled variety, the margins of the sepals being of a deeper tint. It is a distinct and floriferous variety well worth culture.

Blandfordia flammæ elegans (E. G. Henderson).—A stately grassy-leaved plant, bearing a cluster of rich orange-yellow, bell-shaped flowers on the apex of a slender stem 2 ft. in height. It is a distinct and showy cool-greenhouse plant well worth attention.

Clematises.—Margaret Danbar, Xerxes, and Mademoiselle Torriani were shown by Mr. C. Noble, and received floral certificates. A description of them will be found in the report of the Royal Horticultural Society.

Mimulus pardinus fl.-pl. (E. G. Henderson).—An effective semi-double variety of a purplish-crimson colour spotted with black maroon.

Croton Andreanum (Williams).—A robust and showy variety of Continental origin.

Dracæna terminalis alba (Williams).—An effective, free-growing plant having distinct white markings on the younger foliage; admirably suited for decorative and market purposes.

Aralia filicifolia (Williams).—A graceful, cut-leaved species, the foliage of which is of a bright apple-green tint.

Adiantum Williamsi (Williams).—A graceful Fern, already certificated and described.

Microlepia anthesisifolia (Williams).—A slender, finely-divided species, well worth a place in collections.

Dendrobium suavissimum (Low & Co.).—A showy and distinct plant, in habit resembling a strong-growing form of *D. chrysotoxum*; the flowers are borne eight or ten together on a slender, drooping spike, two or more of them being borne at the apex of the spindle-shaped last year's bulbs. The individual flowers measure 2 in. or more in diameter, the petals being broad and having a glossy, wax-like appearance. The whole flower is of a vivid golden tint, the lip being crispulate and fringed, and having a bold, crimson-black blotch in the centre. As regards size and colour the flowers come nearest to those of *D. Cambridgeanum*, and they possess, moreover, a delicate fragrance. Amongst Orchids introduced of late years this is one of the most distinct and effective.

Hardy Japanese Azalea indica Rollissoni (Rollisson & Sons).—A very dwarf and floriferous plant scarcely 6 in. in height, the little tufts of bright green leaves being nearly entirely hidden by double rosy flowers, which remind one of those of rosy-coloured Balsams; it is said to be hardy, and is a distinct and attractive little plant.

Lomaria discolor bipinnatifida (Williams).—A free-growing, bright green-crested Fern, admirably adapted for decorative purposes.

Stove and Greenhouse Plants.—Collections of these came from Messrs. Jackson & Sons, Kingston, Mr. B. S. Williams, Holloway, and Mr. J. Peed, Roupell Park, Norwood. The most conspicuous plants in these collections were Azaleas, *Genetyllis tulipifera*, *Apelexis macrantha purpurea*, *Rhododendron Princess Alice*, *Anthurium Scherzerianum*, *Ixora Williamsi*, *Clerodendron Balfouri*, and one or two Cape Heaths. A magnificent collection of 10 stove and greenhouse plants was staged by Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley; it contained profusely-flowered specimens of *Dracophyllum gracile*, *Anthurium Scherzerianum*, *Bougainvillea glabra*, *Chorozema varium nanum*, *Pimelea mirabilis*. Mr. Wheeler also showed a good collection, in which were Heaths, Azaleas, and *Genetyllis*. Mr. B. Peed, St. John's Lodge, Norwood, had good examples of Azaleas, *Ixora amboynensis*, *Epacris Eclipse*, and *Imantophyllum miniatum*. Six large and well-bloomed Azaleas came from Mr. Ratty, gardener to R. Thornton, Esq. Azaleas in good condition also came from Mr. Turner; conspicuous among them were *gracilis*, *Apollo*, *Charmer*, and *Due de Nassau*. Messrs. Ivory & Sons, Dorking, showed a miscellaneous collection of Azaleas, consisting of small but compact, well-flowered plants. In the amateur class for 12 Cape Heaths, there were three competitors, all of whom staged neatly-grown and well-flowered plants. Mr. Legg, gardener to S. A. Ralli, Esq., Cleveland House, Clapham, had *Erica aristata superba*, *E. eximia superba*, and *E. Cavendishi* in excellent condition. Mr. Peed contributed good plants of *Erica magnifica*, *E. ventricosa coccinea minor*, and *E. depressa multiflora*. Mr. Wheeler, gardener to Sir F. H. Goldsmid, Bart., had good examples of *E. persoluta alba*, *E. depressa*, and *E. coccinea minor*. In the nurserymen's class for 12 Cape Heaths Messrs. Jackson staged well-bloomed specimens of *Erica perspicua nana*, *E. ampullacea obtata*, and *E. florida*; smaller collections of Heaths also came from other growers. Six fine-foliaged plants were exhibited by Mr. G. Legg; amongst these we remarked fine specimens of *Cycas revoluta*, *Stevensonia grandiflora*, and *Croton Wismanni*. Mr. Ley, Croydon, also exhibited a group containing good plants of *Cocos Weddelliana*, *Pandanus Veitchi*, and *Croton angustifolium*. Mr. F. Hill, gardener to H. Taylor, Esq., Avenue Road, Regent's Park, had also a good collection. Six fine-

foliaged plants, consisting of Yuccas, Agaves, and Cycads, also came from Mr. B. S. Williams, of Holloway. Mr. E. Tudgey showed *Pandanads*, Cycads, and *Crotoms*, and a group of exotic Ferns, in which was a very fine specimen of *Alsophila australis*. Mr. Wheeler also had a collection, in which were good plants of *Adiantum Farleyense* and *Lomaria gibba*. Of show *Pelargoniums* there was only one exhibitor in each class. Mr. Turner, Slough, showed six magnificent plants, amongst which were *Claribel*, a variety with white flowers, the upper petals of which were slightly spotted with rosy-purple; *Scottish Chieftain*, a very dark crimson-flowered kind, of neat habit; and *Maid of Honour*, with rich rosy flowers, dark crimson-spotted upper petals, and clear white centre. Mr. James, gardener to W. F. Watson, Esq., Redles, Isleworth, exhibited two collections of well-grown plants, but the flowers were scarcely open; amongst them we noted *Snowflake*, *Pompey* and *Zephyr*, *Sultan*, *Rob Roy*, and *Prince Leopold*. The same exhibitor also showed twelve herbaceous *Calceolarias* in excellent condition. The best collection of *Roses* was shown by Mr. Turner, Slough, who had well-flowered plants of *Madame Lacharue*, *Perfection de Monplaisir*, *Madame Victor Verdier*, and *Souvenir de C. Montaut*. In the same class Messrs. Paul & Sons, The Old Nurseries, Cheshunt, showed good plants of *Madame Lacharme*, *alba rosea*, *Souvenir d'un Ami*, and *Annie Laxton*. Of new *Roses* Mr. Turner had good examples of *Triomphe de France*, a kind with well formed rosy-pink blossoms; *President Leon de St. Jean*, a dark, velvety-crimson flowered kind, very robust in habit, and a black flowered variety named *Miss Hassard*. Messrs. W. Paul & Sons, Waltham Cross, exhibited a miscellaneous collection of pot *Roses*, amongst which were well flowered examples of *Captain Christy*, *Etienne Levet*, *Paul Neron*, *Princess Beatrice*, and *Madame Margottin*. From the same firm also came six boxes of cut *Roses*, amongst which were large and well coloured blooms of *Princess Christian*, *Louise Van Houtte*, *Narcisse*, *Maréchal Niel*, and *Rubens*. Mr. Turner showed two good boxes of *Tulips* in good condition, and a miscellaneous collection of *Auriculas*, among which were some very distinct and good varieties. A collection of *Rhododendrons*, Chinese *Azaleas*, *Spiræa palmata*, and bronze and green-leaved *Acers*, contributed by Messrs. Veitch & Sons, formed one of the most attractive features of the show, and facing this group was another miscellaneous collection of plants sent by Mr. B. S. Williams, of Holloway. Mr. Laing, Forest Hill, contributed a well-grown collection of *Palms*, *Pandanads*, *Caladiums*, *Aralias*, &c.; and opposite these was a group of pot *Roses* from Messrs. Veitch & Sons edged with *Acers*. Mr. Ley showed a collection of Ferns, amongst which we noted fine plants of the Australian Bird's-nest Fern (*Neottopteris australasia*) and *Davillia Mooreana*. Messrs. Cutbush & Sons contributed *Palms*, *Heaths*, and *New Holland plants*; and Mr. Wheeler also staged a group of Ferns, *Palms*, *Azaleas*, and other ornamental plants. Messrs. Harrison & Sons sent well-flowered examples of their new Musk (*Mimulus moschatus Harrisonii*). Mr. J. Mayo, Oxford, showed two boxes of cut blooms of *Maréchal Niel* *Roses*. Mr. Noble, Bagnott, staged a well-flowered group of *Clematises*. Mr. H. Coppin, The Rose Nursery, Croydon, showed herbaceous *Calceolarias* and a collection of tricolor *Pelargoniums*; amongst the latter were well-coloured plants of *Proteus*, *Lady Dorothy Neville*, and *Countess Tasker*. A box of cut *Roses* and *Verbenas* was also shown by the same exhibitor. Mr. Robert Parker showed a collection of old-fashioned border plants, amongst which were good examples of *Narcissus poeticus*, *Scilla campanulata alba* and *rubra*, *Aubrietias*, *Pæonia officinalis rubra*, various *Saxifrages*, *Irises*, and good specimens of *Solomon's Seal*.

Orchids.—Amongst these we noted the following, viz., *Cattleya Mendelli*, with fine white frilled petals, and a carmine blotched lip, several good pans of the Suovy Lady's-slipper (*Cypripedium niveum*), and the speckled *Odontoglossum* (*O. ævium majus*) was represented by several well bloomed specimens. Mr. B. S. Williams had a well grown plant of the last named, bearing six spikes, and also a fine example of *O. Pescatorei*; a large plant of the golden blossomed *Oncidium Marshallianum*, *Dendrobium densiflorum*, with about twenty clusters of golden flowers, and a remarkably handsome plant of the white purple-spotted *Vanda suavis*, bearing four spikes. Messrs. T. Jackson & Son had a still more floriferous example of the last named, bearing seven spikes; *Odontoglossum citrosum roseum*, bearing seven spikes; *Saccolabium retusum*, having six graceful rosy-white speckled flowers; and a plant of *Cattleya Mossie superba*, having twelve clear rosy-carmine flowers. Mr. Denning sent a splendid group of Orchids from Lord Londesborough's collection, including a remarkably vigorous plant of *Odontoglossum citrosum*, bearing three large spikes, one of which was branched at the base, and bore twenty-five flowers; a plant of the star-like white-purple blotched *O. Roezli* was furnished with fourteen large flowers; and a well grown pan of *O. Pescatorei* bore five or six spikes; on the vivid carmine petalled, crimson-purple-lipped *Cattleya superba* there were four perfect flowers; and the bright rosy-carmine *Dendrobium Parishii* bore five or six well-bloomed pseudo-bulbs. Mr. Child sent his large specimens of *Oncidium amplicatum* and *Cypripedium barbatum*, to which we have elsewhere alluded, and a handsome plant of the graceful *Aerides Fieldingi* bearing four good spikes. Mr. Philbrick showed a well-bloomed plant of *Epidendrum vitellinum majus* bearing nine or ten spikes of orange-scarlet flowers, and a large plant of *Dendrobium densiflorum* fully 4 ft. in diameter, a mass of fresh foliage, and large drooping trusses of flowers. Mr. Newman contributed six well-grown plants, among which we remarked *Phalenopsis Ludemanniana*, bearing forty or fifty flowers; a well-grown pan of *Cypripedium barbatum*; *Dendrobium Wardianum*, a vigorous mass bearing twenty-six flowers; and a healthy example of *Cypripedium Stonei* bearing four large, richly-coloured blooms on a stout scape 2 ft. in height. Perhaps the most noticeable plant in this group was a graceful example of the handsome *Dendrobium Falconeri*.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CUT FLOWERS:*

CLASSIFIED ACCORDING TO COLOURS AND SEASON WHEN OBTAINABLE.

DURING last year readers of THE GARDEN were furnished every month with a list of flowers which were then in season, and which could be either found in Covent Garden market or could be procured by being ordered of the florists there a couple of days beforehand. From these monthly lists Orchids and rare stove plants were excluded. It has occurred to me that it might be interesting to some, and useful to others, if I were to tabulate the information contained in those lists in a manner which would show at a glance, not only what colours are obtainable during each month, but also for how long such colours may be calculated upon as being available, and at what seasons they are to be had in the greatest variety. The tabular form in which they are now arranged will, I apprehend, be interesting to those who care to examine such questions as the proportions in which different colours enliven our fields and gardens, and the extent to which the preponderance of certain colours is influenced by the season of the year. To professional florists, these tables are not likely to be of use, unless they may suggest to them the introduction into their trade of some flowers not at present grown by those on whom they depend for their supplies, and who are always ready to grow any new plant for which there is likely to be a demand. In illustration of this I need only refer to the comparatively recent introduction to Covent Garden of forced Spiræas, Lilacs, Solomon's Seal, Orchids, &c. But to the amateur bouquet-maker and floral decorator, and also to many a gardener who is not in constant practice in this branch of art, I believe that these tables are likely to prove useful, and one illustration will suffice to explain in what manner:—It is a common occurrence in the trade to receive an order (and it therefore cannot be unusual for a gardener to be requested) to make up a bouquet or a head-dress that will "go" with a dress of a certain colour, a piece of which is forwarded. Now every gardener knows the colour of all the flowers which he grows, but every gardener does not, by a very long way, grow all flowers, or even all colours. When therefore he cannot find, under his own charge, flowers of the precise colour which he wants, a glance at these tables will most probably remind him of some other flower which will answer the required purpose, and which he can procure from some neighbouring gardener or nurseryman.

Blue Flowers.	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Campanula ..												
Cineraria ..												
Cornflower ..												
Eranthemum ..												
Gentianella ..												
Hepatica ..												
Hyacinth ..												
Italian Alkanet ..												
Iris ..												
Larkspur ..												
Lobelia ..												
Myosotis ..												
Nemophila ..												
Omphalodes verna.												
Pansy ..												
Salvia patens ..												
Siberian Squill ..												
Witsenia ..												

In the above list of blue flowers there is not one that I can recommend as a good colour by candlelight. All the darker shades then appear nearly black, while the lighter shades assume a grey tint. Perhaps *Nemophila* comes out better than the rest from the ordeal of artificial light. The stems of this

The months in which the flowers of the various colours bloom are indicated by a dash, thus (—).

flower, and also of *Hepatica* and *Lobelia*, are so slender that they need the support of a wire to keep them up. *Gentianella*, *Eranthemum*, and *Larkspur* are useful for pinushion arrangements; but if used in other ways they generally require an artificial stem. *Salvia*, *Omphalodes*, and *Alkanet* should be gummed round the outsides of the corollas to prevent their falling out of the calices. *Iris* blooms look better by themselves, set off with broad-leaved Grasses, than when mixed with other flowers. *Witsenia* is one of the least common and best blues we have, and should be found in every greenhouse.

Purple Flowers.

	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Anemone ..												
Aster ..												
Cineraria ..												
Crocus ..												
Heliotrope ..												
Hollyhock ..												
Hyacinth ..												
Iris ..												
Larkspur ..												
Lilac ..												
Lupine ..												
Michaelmas Daisy ..												
Pansy ..												
Phlox ..												
Ranunculus ..												
Scilla bifolia ..												
Sweet Pea ..												
Syrian Hibiscus ..												
Tulip ..												
Verbena ..												
Violet ..												

The foregoing list of purple flowers, like the preceding one, is more suitable for daylight decorations than for those required in the evening. The judicious use of wires of different thicknesses will be found of great advantage for many of these flowers. Violets require support unless they are massed in bunches, an arrangement which must be condemned as heavy and unnatural. If *Cinerarias* or *Michaelmas Daisies* are to form portions of a mixed bouquet, wire stems prevent a great waste of floral material. The blooms of annual *Asters*, *Anemones*, and *Ranunculuses* are so heavy that the assistance of stout wire keeps them in form for a much longer period than they would be without it. *Lilac* and *Heliotrope* are both the better for a piece of thin wire twisted round the flower-stem.

Lavender or Mauve

	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Agapanthus ..												
Aster ..												
Chinese Primrose ..												
Chrysanthemum ..												
Cineraria ..												
Cyclamen ..												
Dahlia ..												
Fuchsia ..												
Heath ..												
Hollyhock ..												
Hyacinth ..												
Iris ..												
Pansy ..												
Primrose ..												
Ranunculus ..												
Stokesia ..												
Tulip ..												
Violet ..												
Wistaria ..												

The lavender and mauve flowers have been included in one list, because it is difficult to draw the line between the two colours. They range from the bluish-lavender of *Agapanthus* and *Stokesia* to the crimson shades of mauve which we find in certain *Primroses*, *Dahlias*, *Chrysanthemums*, and *Tulips*. It is usual to arrange *Hollyhocks*, *Dahlias*, and *Chrysanthemums* in low flat dishes; but much more effective displays may be made of these large flowers if they be placed in more natural positions, provided that the necessary wire supports are concealed from view. *Wistaria* makes a most useful droop or fringe for a tall dish or vase; but if it be required to keep it in a horizontal position, a fine wire twisted round the flower-stalk up nearly to the point is a great assistance.

Pink Flowers.	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Almond												
Antirrhinum												
Aster												
Azalea												
Begonia

Zinnia												
Zonal Pelargonium												

This list of Pink flowers is nearly twice the length of either of those preceding it, and there are but few in it which do not look as well by lamplight as by daylight. Camellias and Roses generally require to have three wires passed through them horizontally near the base of the flower, and the six projecting ends turned down and fastened to the stem, or (where the stem has been removed) to a substituted stem. Epiphyllums always require a wire stem, and care should be taken to curve the flower so that it may hang in a natural way. The same remark applies to Fuchsias, where single blooms have to be made use of. Pelargoniums and Azaleas require to be gummed, the former inside the corolla, the latter outside. Gladioli look best alone, and so do Pyrethrums; their foliage in each case being the best companion, failing which, use Grasses with the Gladiolus, and Ferns with the Pyrethrum. Dielytra never looks better than when grouped with Solomon's Seal.

Orange Flowers.	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Abutilon												
Calceolaria												
Carnation												
Chrysanthemum												
Cowslip												
Crocus												
Dahlia												
Erysimum												
Eschscholtzia												
Hollyhock												
Lily												
Marigold												
Narcissus												
Polyanthus												
Potentilla												
Rose												
Tulip												
Zinnia												

Amongst orange flowers, Abutilon will always hold a high place in the estimation of decorators for fringing large bouquets or vases, and there is scarcely any period of the year when a least one or two blossoms may not be found upon a strong

plant of it, for it is one of our most continuous-blooming greenhouse shrubs, and there are several varieties of it. Some of the new Lilies are well worth cultivating for decorative purposes, as also the older species. The Tea Roses give us some soft shades of orange, and they can be had all the year round. Some of the double Zinnias are very handsome.

Yellow Flowers.	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Allamanda												
Alyssum												
Antirrhinum												
Azalea												
Broom												
Buttercup												
Calceolaria												
Carnation												
Chrysanthemum												
Coronilla												
Cytisus												
Dahlia												
Eschscholtzia												
Genista												
Globe-flower												
Gorse												
Hollyhock												
Iris												
Jasmine												
Lachenalia												
Marigold												
Narcissus												
Polyanthus												
Potentilla												
Primrose												
Rose												
Sternbergia												
Tulip												
Wallflower												
Water Lily												
Zinnia												

Yellow flowers generally do not look so well by candlelight as by daylight, all but those of a very rich tone appearing nearly or quite white under any illumination excepting that afforded by the sun's rays. Sternbergia is a fine, old-fashioned, hardy Amaryllis, which one rarely sees out of nursery gardens; were it only a spring-flowering bulb, it would be more highly esteemed. Allamanda is one of the most free and continuous flowering of our stove plants, and I prefer before all the species the small-blossomed one which, curiously enough, is called *A. grandiflora*. Coronilla glauca is a valuable plant, since it flowers so late in the autumn, and in mild seasons and favoured localities furnishes us with blossoms out-of-doors all through the winter. Both the winter and the summer Jasmines are too apt to shed their flowers; but this can easily be prevented by placing a little gum around the corolla.

Scarlet Flowers.	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Anemone												
Begonia												
Bouvardia												
Carnation												
Dahlia												
Epiphyllum												
Euphorbia												
Fuchsia												
Gladiolus												
Kalosanthes												
Lily												
Poppy												
Potentilla												
Ranunculus												
Salvia												
Sweet Pea												
Tropeolum												
Tulip												
Verbena												
Zinnia												
Zonal Pelargonium												

Scarlet flowers are not so numerous as crimson; nevertheless they make up for this shortcoming by the intensity and brilliance of their colour. The tuberous-rooted Begonias are a valuable addition to the list, being available in many shades

of scarlet. *Euphorbia jacquiniæflora* is one of the florist's most useful plants, being convertible to so many uses, its flowers (though not its leaves) lasting well without water. *Salvia*, too, is an important genus amongst scarlet flowers, the winter-flowering species lasting for a long period, but all the varieties require the corollas to be ginned outside. *Bevardia* is also valuable for small decorations, but every blossom needs to be wired. There are few flowers of more noble appearance than the Lilies, and the double variety of the Tiger Lily is a grand addition to our gardens.

In the list of white flowers just given there is a much larger variety to choose from than in any previous list. This is partly owing to the tendency which many plants with coloured flowers have to produce white-flowering variations, which are always acceptable, white being the orthodox colour for all natural, hymeneal, funereal, and ecclesiastical decorations. *Arum* does not group well with other flowers, and nothing but its own leaves really show it off to advantage. *Tuberose* and *Eucharis* require artificial stems. *Staphylea*, *Crassula*, and *Lily of the Valley* keep their forms better, if they have the support of a wire twisted round their stems. The massive bloom of the *Water Lily* requires the aid of a stout wire passed up its stem into the base of the flower, if required to remain upright. *Abutilon* and *Lapageria* are invaluable for drooping effects. *Solomon's Seal* is a most graceful plant, and is a beautiful addition to almost any bouquet of mixed flowers.

White Flowers.	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Abutilon												
Alyssum												
Andromeda												
Anemone

Ranunculus												
Rhododendron												
Ribes												
Rose												
Spiræa palmata												
Stock												
Sweet Pea												
Sweet William												
Tulip												
Vallota												
Verbena												
Zinnia												

More than half of the crimson flowers here enumerated have been mentioned previously, because pink varieties of them are to be had. The remainder are, however, sufficiently distinct both in form and colour to justify a separate list. *Poinsettia*, *Lapageria*, *Kalosanthes*, and *Vallota*, for example, have each a character peculiar to itself, and require to be treated accordingly. *Polyanthus*, particularly the laced varieties, are deserving of more attention than they often receive, and they look well with *Primrose* leaves when their own cannot be spared. *Foxgloves* look best in tall vases; *Rhododendrons* require to be grouped by themselves. *Bells of Lapageria*, wired to a spray of climbing *Fig*, show to advantage when arranged spirally around the stem of any tall vase.

I cannot presume to believe that the foregoing tables are absolutely free from error, though I have taken considerable pains to make them as complete and accurate as I could. In addition to this, Mr. T. A. Dickson, of Covent Garden Market, has been good enough to carefully revise each list after it had been printed. Your readers may therefore regard this communication as the result of some years' obser-

vation by an amateur, checked by the professional knowledge of one of the most experienced dealers in the largest of British flower markets. W. T. T.

NOTES OF THE WEEK.

CANON HOLE ON THE SUNDAY OPENING OF PUBLIC GARDENS.—At the Manchester Show the other day Canon Hole spoke strongly in favour of the opening of gardens on Sundays. If he were told, "Would not you rather the people went to a place of worship?" his answer would be, "Why shouldn't a garden be a place of worship?" At all events, it is a better place of worship than a public-house.

RHODODENDRON CINNABARINUM.—This handsome Rhododendron is now in full bloom here in the open air, where the plant has stood uninjured without protection for many years past. It occupies an elevated situation, very dry, and open to the south, but it is well sheltered otherwise by evergreen trees and shrubs. The flowers, which are delicately scented and of a rich, orange-scarlet colour, are very useful in a cut state. Altogether it is one of the prettiest flowering evergreens which we possess.—JOHN GARLAND, Killerton, Eeeter. [It is a species to which, as grown at Killerton, the hack-nied term "splendid" may be justly applied.]

THE WHITE HYDRANGEA.—This plant has at last justified all the praises its introducer, Mr. Thomas Hogg, gave it on passing through London last year. Messrs. Veitch's specimens show that it is not only a good white, as Mr. Hogg informed us, but forms a fine free head of bloom. It is really what is sometimes called an "every-body's plant," and will no doubt soon find its way into every garden. It will form a fitting companion for the fine masses of blue and pink Hydrangeas which now adorn so many gardens in autumn.

AZALEA MOLLI8.—This new Azalea, of which we figure two varieties this week, has recently been abundantly introduced to our principal nurseries, where it may be readily obtained. It is extremely hardy, and also seems to bear forcing well.

ANEMONE PALMATA.—A single specimen of this somewhat rare and beautiful herbaceous plant is now flowering in Messrs. Backhouse's nursery, York. The flowers, which are large in proportion to the size of the plant, measure about 2 in. in diameter, and are of a soft orange-yellow colour. The plant grows from 4 in. to 6 in. high.—R. P.

DENDROBIUM BRYMERIANUM.—This, one of the most distinct of all the Dendrobiums, is just now blooming in Messrs. Veitch's nursery at Chelsea. It is slender in habit, and appears to be a free grower. Its flowers are nearly 2 in. in breadth, and of a uniform golden-yellow. The most characteristic portion of the flower is the rounded, deeply cleft, and elegantly-fringed margin of the lip, which is cut into ciliated lobes nearly 1 in. in length. This is one of the most beautiful of all the fringe-lipped Dendrobiums.—B.

GOOD DOUBLE CINERARIAS.—Double Cinerarias have not, as a rule, hitherto recommended themselves much, and indeed, have often been so ugly that one could hardly fail to regret their discovery. Messrs. Dickson & Co., of Waterloo Place, Edinburgh, however, have some varieties which are really double and richly-coloured; these are named Pink Perfection, Prince, and Queen of Violets. This last is the prettiest double blue or purple flower which we remember to have seen; the other two are also richly coloured. They are said to bloom profusely, and to make good pot plants.

GROUPS OF HARDY FLOWERS, &c.—Narcissus moschatus is a charming Daffodil, too rarely seen in cultivation. It resembles most nearly in shape the common N. Pseudo-Narcissus, but is of a pale sulphur, almost white, colour throughout. It flowers fully a month later than the common Daffodil. A brilliant contrast is obtained by planting it alongside of Anemone fulgens, lately figured in THE GARDEN. Another good arrangement of colours in a mixed border results from placing the dwarf Iris pumila in front of a clump of Jonquils; the delicate Aquilegia canadensis should grow near the St. Bruno's Lily (Antherium hiastrum), and Myosotis Imperatrice Elizabeth makes a more enduring group with Geranium macrorrhizum. Of bedding Violas there is no yellow which pleases me so much as the delicate lemon-coloured V. Grievi; if left in position for two years with Viola Bluebell the result at this season is truly beautiful. I have a diamond-shaped bed planted very satisfactorily just now. In the centre is a plant of the evergreen Cistus ladaniferus, and at each angle a tuft of Carex japonica variegata; the rest of the bed is planted with red Anemones coming through a ground of Viola Bluebell and Grievi; the former Viola (being rather taller) occupies the centre, and Grievi surrounds it. Mixed with the Anemones at the time of planting were many bulbs of Iris hispanica, whose strange flowers come as th

Anemones go. The plants of Viola are two years old, as such bloom much earlier and more profusely than young plants. A very sweet bed of Crucifers may be made as follows:—Centre, purple Honesty surrounded by blood-red Wallflower, next to which comes Belvoir Yellow Wallflower surrounded by Arabis albidia variegata, the outer line (which may be omitted in small beds, or the central clump of Honesty may be dispensed with) being Aubrietia grandiflora. This is a striking bed, in great favour with the bees; the Aubrietia should not be disturbed.—SALMONICERS.

VERONICA HULKEI.—Though seldom seen, this is one of the most useful plants which we possess for the spring decoration of the conservatory. Under liberal culture, it produces long, wreath-like branches that flower freely in May and June, and when associated with other flowering and ornamental-leaved plants, it is very effective. Its flowers are bright lavender in colour. Plants of it may now be seen in good condition in the greenhouse at Kew, but their branches are trained in such a way as to give them much too formal an appearance.—S.

GENISTA PRECOX SULPHUREA.—Large plants of this Genista growing on mounds and rockwork in Mr. Ware's nursery at Tottenham, now rank amongst the most attractive, hardy, flowering shrubs to be found near London. They are allowed plenty of room, and growing, as they do, equally on all sides, and being loaded with bloom, they are exceedingly effective.—C. S.

CRINUM AUGUSTUM.—A plant of this in the Pine-apple Nursery is now furnished with a remarkably strong flower-spike from 3 ft. to 4 ft. in length, which is surmounted by sixteen large Amaryllis-like flowers of a bright purple colour and powerfully scented.—S.

ANDRÉ'S ANTHURIUM.—M. E. André's fine discovery (Anthurium Andreeanum) is well figured in the last number of the "Illustration Horticole." M. André describes it as superior to the well-known Anthurium Scherzerianum, and the plate shows it to be a very distinct and beautiful plant.

A VERY MILD WINTER AND A VERY LATE SPRING.—It was reported at a recent meeting of the Edinburgh Botanical Society by Mr. McNab that vegetation in the Botanical Gardens was about three weeks behind, and that this had been the most backward spring recorded for twenty-eight years past.

POISONING BY MUSHROOMS IN FRANCE.—The neighbourhood of Agen has been placed in a state of consternation by the death of eight members of the same family through eating Mushrooms. This fatal example is a warning for those who persist in the use of Mushrooms of doubtful quality.—L. M.

BATH AND WEST OF ENGLAND ROSE SHOW.—We understand that in the horticultural department of the forthcoming Show of this Society, to be held at Bath, from the 4th to the 8th of June, two tea-guinea cups, one for amateurs and one for nurserymen respectively, will be awarded for cut blooms of Tea Roses. A jury consisting of three nurserymen will judge the amateurs' collections, and a similar number of amateurs will award the prizes as regards the nurserymen's productions.

FRUIT PROSPECTS IN SUFFOLK.—These are worse than I had anticipated. The Peach, Nectarine, and Apricot crops are quite a wreck, and early Plums and Pears are also destroyed; even Pear blossoms that seemed to have escaped are now falling in handfuls, and fruits that appeared set have turned yellow and are dropping off till hardly one remains. The Apple blossom is abnormally late, and looks paler and weaker than usual, still there is sufficient bloom for a full crop if it set well; but the wind has again shifted to the north-east, and to-day (May 23) is much colder than the weather was in April. All vegetation is wonderfully late, and the fruit prospects are as gloomy as can well be. In addition to this there threatens to be the loss of many of the trees. Owing to the mildness and wetness of the season some of the trees, notably Apricots, never seemed to go to rest properly, and several attempted to put out green leaves in winter. All such trees are now dying or dead—even those protected by glass copings and an extra supply of boughs. Most of the leaves on the Apricot trees are partially curled, and have a pale whitish appearance as if infested with mildew, and thousands of these leaves drop when touched; the leaves and young wood have, in fact, the appearance as if they had been dipped in scalding water, and it will be a difficult matter to save the trees.—D. T. F.

Ancient Names for the Holly.—I see it stated by Mr. Ellacombe, in his interesting articles on the "Plant-Lore of Shakespeare" (see p. 371), that "Hulver," the old term for Holly, is gone out of use. That is not quite the case, as the poorer classes in this neighbourhood, and I believe in the greater part of Norfolk, still use it, and there are some few who recognise it by no other name.—E. F.

CONIFER SCREENS AND THEIR USES.

AMONGST the many ways in which Conifers may be utilised, not the least useful is that of employing them for screens. Whether the object be to shelter a comparatively large area from tempestuous and cutting winds, or whether a somewhat close, impenetrable protection be required for small subjects, there is, owing to the vast variety of growth exhibited by the Coniferous tribes, no lack of fitting subjects for such purposes. It has been recently shown in THE GARDEN how successfully evergreens may be used in the way of creating shelter, and there is no doubt that many districts, which as regards situation and soil are well adapted for fruit culture on a large scale, would be extremely valuable for that purpose, could strong gales and keen winds be warded off, or at any rate broken in force. By the selection of proper kinds of Conifers, and judiciously planting them, this result might in many cases be obtained. Thick, closely-trimmed evergreen hedges are invaluable to those who have pot plants to place out-of-doors during summer; they are in every way preferable to walls for that purpose, inasmuch as there is a constant filtration of air through them, and the surrounding atmosphere cools down quickly after the heat of the day is passed. Taking into consideration what demand there always is for protection, both in the spring, when sheltered, sunny spots are so valuable for the forwarding of many plants, and in summer, when cool, shady places are always at a premium, it is somewhat surprising that these evergreen walls are not more extensively employed than they are. One of the most efficient forms of shelter which I ever saw was a series of Thuja hedges in the form of a half circle. They were 9 ft. apart, which allowed of a 3 ft. path and 6 ft. border, and were about 7 ft. in height. They were planted to run from east to west, whilst three broad roads cut through the whole from north to south; the space thus occupied would be about a quarter of an acre. Such plants as Camellias, Azaleas, Oranges, New Holland plants, &c., here received ample protection from wind and sun, while at the same time they obtained a proper amount of light, as, owing to the disposition of the hedges, the sun shone fully at some time of the morning or afternoon on the plants set between them; it was only during the middle part of the day that sunshine was entirely shut off. A constant circulation of air, too, was maintained amongst them. Screens of this description, about 9 ft. high, running north and south, are extremely serviceable for growing such soft-wooded plants as require a maximum of light and air, but at the same time they must be protected from a scorching sun. If frames were placed on the east side, the great heat of the day would be over, as far as they were concerned, about one or two o'clock; they might then be unshaded and damped down, and thereby get the advantage of unfiltered light for some hours longer than those placed in a southern aspect could have. This is a grand advantage, especially for such plants as Primulas, Pelargoniums, &c., which have to make their growth in the latter part of the summer, and which it is absolutely necessary

to endow with a sturdy habit and robust constitution. At Mr. Anthony Waterer's, at Woking, may be seen many examples of these evergreen screens, which are extensively employed to shelter the choicer kinds of Rhododendrons and Azaleas against driving rains and tempestuous winds. These screens possess the merit of never being unsightly; in summer they are easily kept in order, and in winter they have a warm, comfortable appearance. The Thujas are probably the best adapted for this purpose, as they are robust growers and bear clipping. One of the best is *T. plicata*; it is extremely hardy, and has a somewhat peculiar overlapping habit, which gives it a neat appearance. *T. occidentalis* I have seen much used; also *T. Lobbi*, which is a quick grower, but I do not know if it is in other respects well adapted for a screen. It is essential that the kinds used for such a purpose should be very hardy, robust growers, and not liable to get naked at the bottom.

Bylect.

JOHN CORNHILL.

Our Woodland Flowers.—May is perhaps the richest month of the year as regards woodland or wild flowers, and, let the season be what it may, they never fail. Suffolk is especially well favoured in this respect by Nature, for every coppice or dell has some peculiar feature of native wealth peculiar to itself, the most abundant displays being in districts in which the forest consists of deciduous trees, such as Oak and Ash, at sufficient intervals apart to allow the underwood to freely develop its growth. In such positions both shelter and shade are afforded, and consequently a protracted and effective floral display is the result. The Primroses are not yet faded, but are almost overgrown by Oxlips, Cowslips, wood Violets and wild Strawberries, Orchises, white and red Dead Nettles, Catchflies, and a host of other subjects; while the foliage of Arums, Burdocks, and huge Thistles suggests a sub-tropical accompaniment. If any low-lying marshy portions of the

Artificial Lake and Islands.

woodlands be visited, beds of wild Hyaciaths, mingled with gorgeous clumps of *Caltha palustris*, or Marsh Marigold, intermingled with Reeds, Rushes, and wild Grasses, form such a display that quite upsets our orthodox notions of spring gardening. No violent or sudden transitions are observable in Nature's gardens. Where, however, the fashionable style of decoration is carried out, there is no help for it but to remove Pansies and other lovely spring flowers just as they are approaching their best to make room for the next course, while they are, in gardening phrase, laid in by the heels, and wasting both beauty and fragrance on the desert air of shrubby recesses or back borders, until again required for spring work.—J. GROOM, Henham.

Needless Structures in Picturesque Garden Scenery.

—The accompanying scene represents one which has considerable beauty, but which is partially marred by a miserable kiosk impudently placed on the brow of the prettily-planted island. This is essentially an engineering and architect's notion. Given a lovely scene, and there is no good excuse for making an important building on an unfrequented islet. But something can be done—a kiosk! Accordingly the very central object in this beautiful garden scene, made with painful care and not without happy results, is a structure midway between a pigeon-box and a small pagoda. There are, how-

ever, so many trumpery buildings in the world, that it is hardly worth while adding to them in scenes formed for beauty and for rest. We have taken the liberty of omitting the kiosk from our sketch.

OUTDOOR CHRYSANTHEMUMS.

MANY who have been in the habit of blooming Chrysanthemums under glass entertain doubts as to the practicability of obtaining fair-sized blooms for exhibition purposes out-of-doors, but I hope to be able to set all doubts as respects this matter at rest. At the Woolwich Chrysanthemum Show classes are set apart for outdoor culture (*i.e.*, for members who have no glass structures), and there are also classes for those who possess glass structures. Mr. Marshall, a painstaking outdoor Chrysanthemum grower, has, however, for these last two or three years competed with those who have glass, and at the exhibition of 1876 (notwithstanding the disadvantages under which he laboured) he secured two first prizes in the classes in which he showed, and that notwithstanding there was a severe competition. This I merely quote to show that the obtaining of exhibition blooms out-of-doors is perfectly practicable, and, furthermore, that it does not entail so much labour in potting, watering, &c., as in the case of indoor plants; I am, nevertheless, fully alive to the disadvantages that attend outdoor Chrysanthemum culture: the blooms should not be allowed to get wet, or drip to fall upon them, as their appearance is materially depreciated thereby. I do not recommend dwarf specimens to be flowered out-of-doors, as some kind of glass structure is necessary to bring out the large numbers of blooms that are produced by this particular class of plants, although it is possible to flower standards perfectly by means of the aid of a canvas covering only. The best standard Pompones, indeed, which I ever grew were bloomed under the conditions just named, and notwithstanding the occurrence of a very severe frost that year, I obtained a first prize for six, a fact which alone suffices to dispose of the impracticability, often urged, of getting good blooms out-of-doors.

Preparation of the Ground and Planting.

Having selected the spot upon which it is intended to grow the plants, the ground should be well dug over to the depth of at least 16 in., in order to enable the roots to get well down, and thereby avoid drought. Give a good dressing of manure, not too rotten, working it well in when digging, and then tread the whole firmly to avoid sinking after the plants are put out. Mark out the ground in double rows, leaving between the rows a space of at least 2 ft., to afford a free passage between them. This will facilitate the operations of tying and disbudbing, &c., and will enable the grower the more readily to secure earwigs and slugs, both of which are very fond of Chrysanthemums, and must be kept in check by constant watching and trapping. Draw out the soil in the double rows to about 6 in. in depth, and after a good watering and the settling down, proceed to plant about 12 in. or 18 in. apart, the latter being preferable, taking care to have the dwarfest in front and the tallest at the back. Where the plants have to be purchased, the relative heights of the different varieties may be obtained from the dealer. A good stout stake should be attached to each plant, which must be allowed to grow without check, with the exception of Pompones, which may be stopped once or twice during the summer. Water them frequently both night and morning with a watering-pot, fairly washing them from head to foot, and after August frequent doses of liquid manure may be given with advantage; they should be disbudded in the usual manner, and after that has been done the use of clear water must be discontinued, and liquid manure given at every watering; in fact, at this stage little water need be given, the rains that usually fall in autumn affording sufficient moisture, and as the roots will be rising to the surface of the ground, a top-dressing consisting of equal parts loam and manure should be given to the depth of 6 in. thus bringing the beds level with the path. About the first week in October a few small sticks may be placed between the supports, to which the blooms may be tied down to a level, or rather sloping from the back to the front, covering the whole with calico or canvas, and allowing it to drop 1 ft. or 2 ft. below the blooms at front and back, in order to keep them in

good condition. If these instructions be carried out, a fine display will be the result.

Varieties.

LARGE-FLOWERED.—The following are a few of the very best for outdoor planting, viz.:—Aimée Ferrière, Antonelli, Auguste Mic, aureum multiflorum, Belladonna, Beverley, Cherub, Christine, Countess of Granville, Dr. Sharp, Duchess of Roxburgh, Eve, Faust, Fingal, General Slade, Golden Beverley, Golden Christine, Guernsey Nugget, Hermione, Julie Lagravere, Lady Slade, Mr. Evans or Oliver Cromwell, Mr. George Glenny, Mrs. George Rundle, Mrs. Sharpe, Orange Annie Salter, Pink Christine, Prince of Wales, Progne, Prometheus, Sparkler, Venus, and White Venus.

ANEMONE-FLOWERED.—Fleur de Marie, Gluck, King of Anemones, Mr. Cole, Prince of Anemones, Princess Louise, Antonius, Astarte, Madame Montels, Miss Nightingale, Mr. Astie, Perle, Regulus, and Stella.

POMPONE.—Annie Forsyth, Bob, Cedo Nulli (lilac, golden and white), Dipellon, Fanny, Flambeau, Hélène, La Vogue, Lilliputienne, Louisa, Madlle. Marthe, Mrs. Dix, St. Michael, and Souvenir de Jersey.

I have omitted all mention of the Japanese varieties, as they are unsuited for outdoor purposes. The names, too, of many of the finest and largest exhibition sorts are absent from the list because they do not grow well when treated in the manner described; planting them would therefore be simply a waste of time and expense, and end in disappointment.

Plumstead Common.

F. T. DAVIS.

Hardy Clematises and their Uses.—Few plants are capable of being used in so many ways as Clematises. They may either be employed for furnishing walls and pillars out-of-doors or in cool conservatories; for overrunning tree stumps and shrubs; for bedding purposes, they are admirably adapted, and when well grown they furnish a mass of gay flowers for months during summer. In order to induce Clematises to produce a long succession of bloom, liberal culture is necessary—indeed indispensable; for, unless a vigorous growth in the plants is secured, they will flower but sparingly. A deep, well-drained soil consisting of good, friable loam, rotten manure, and leaf-mould, is the best compost in which to plant them, and during very dry weather liberal supplies of weak manure-water may be given them with advantage. Although the choicer kinds are usually increased by grafting, if cuttings of the young shoots be taken off in spring and inserted in a gentle bottom-heat under a hand-glass, they will form good flowering plants under favourable circumstances the following season.—S.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Orchis pallens.—This pretty pale yellow Orchid has been in beautiful bloom for the last three weeks planted out in a cold pit; *O. insectiflora*, *Serapias Linza*, and *Freesia Leichtliniana* are also in bloom under similar conditions.—H. HARPER CREWE.

Birds'-claw Violet (*Viola pedata*).—This pretty Violet begins to bloom now, and continues to do so for a long period. For several years I vainly endeavoured to flower a coarse-growing spurious variety of it that had been received as the true kind. *V. pedata* proper is small, the leafstalks short, and the leaves finely cut, hence the designation Bird's-claw. The flowers are of a bluish mauve colour, and in form intermediate between the Violet and Pansy. They are borne in great profusion, and no Alpine garden should be without this mountain gem.—A. D.

Effect of the Winter on White Lilies.—It is discouraging to find that, owing to the unusually wet winter which we have had, large beds filled with plants of the common White Lily, which looked healthy at Christmas, have been so much injured by wet since that few of them will flower this season. This is at least the case near London; a large grower of this old-fashioned Lily showed me the other day beds, which he had expected would yield £10 worth of cut bloom, completely rotten and worthless.—S.

Cobæa scandens a good Balcony Climber.—This is one of the best plants that can be used during summer and autumn for the decoration of balconies; or for training round window-sills or on porches. It grows rapidly and flowers freely in warm weather, and a little cold does not injure it. Cuttings of it put in now and kept in gentle heat for a few weeks will strike root readily and make good plants for turning out-of-doors early in June. They should, of course, be well hardened off previously to being exposed, and if planted in well-drained, rich, sandy soil, they succeed well even in London.—S.

Andromeda Leucothoe fl.-pl. for Vases.—This beautiful spring-flowering North American shrub does not appear to be nearly so commonly in use about London as its beauty and adaptability for furnishing vases, balconies, window sills, &c., would lead one to expect. Neat little plants, 1 ft. high and as much through, are easily obtained, and when laden with their creamy-white, bell-like blooms, would be far more appreciated than the many wretched specimens of Aucubas and other shrubs commonly seen in and around London.—W. S.

CHINESE MODE OF PROPAGATING ARALIAS.

The mode of propagation, of which the annexed cut is an illustration, is one of great antiquity, it having been employed by both Chinese and Indian cultivators from time immemorial, a joint of a Bamboo stem or a bag of wet earth and Moss being substituted for the flower-pot. This plan of propagation is peculiarly well adapted for tall-growing Aralias or Dracenas, which, having lost their lower leaves, have become unsightly. The process consists in fitting the two halves of a flower-pot around the base of the young stem just below the leaves, at which point the bark may be slit with a knife or otherwise abraded so as to induce a "callus," which precedes the protrusion of young roots. The pot is then filled with moist soil or soil and wet Moss, and in some cases the old stem is partially

Old-fashioned plan of propagating Aralias.

severed just below the pot, as shown in the engraving, which represents the digitate-leaved *Aralia pulchra*, one of the most distinct and effective of all half-hardy, evergreen, fine-leaved plants. B.

Hybrid Narcissi.—The late Dean Herbert clearly showed that many of the so-called species of Narcissus were in reality cultural hybrids, and Dr. Henon, who especially studied the French species of Narcissi, pointed out as long ago as 1840, that in a meadow at Lattes, near Montpellier, might be seen natural hybrids between *N. poeticus* and *N. tazetta* passing through *N. biflorus* without any appreciable line of demarcation. By crossing *N. poeticus* and *N. pseudo-Narcissus* Dean Herbert produced a plant nearly identical with *N. incomparabilis*, and experiments conducted by himself and Mr. Trevor Alcock proved *N. adonis* to be a hybrid between *N. pseudo-Narcissus* and *N. jonquilla*. Among other seedlings raised by Herbert were hybrids between *N. poeticus* and *N. pseudo-Narcissus minor*; *N. poeticus* and *N. montanus*; and *Tazetta* (var. "Staten general") and *N. pseudo-Narcissus*. Mr. Leeds, of Longford Bridge, Manchester, has also raised some beautiful hybrid kinds, and of these some of the most distinct and interesting were exhibited at a recent meeting at South Kensington, where they attracted much attention.—B.

THE INDOOR GARDEN.

FILMY FERNS IN PLANT CASES.

SOME account of the mode of treatment under which these Ferns thrive with me in cases may not be unwelcome to your readers. The compost which I use consists of charcoal, freestone or sandstone, old mortar, the best Orchid peat and silver sand, all used in a rough state. Good drainage is indispensable. Water is given sparingly during autumn and winter, but as soon as signs of fresh growth make their appearance, the plants are watered overhead every morning through a fine rose; on summer evenings they are gently syringed. The doors of the cases are left ajar after watering for a time to allow a circulation of air among the plants, the top of the case being always open. The temperature of the case is that of a greenhouse with a northern aspect. The Ferns are planted on a slight mound in the centre of the case, and a thick covering of fresh Sphagnum grows over the compost. As will be seen by the annexed sketch, the shape of the case is octagonal, with a pyramidal top terminating in a circle. A A are folding doors, B receptacle for drainage and compost, C outlet for water, D top ventilator. Plants of *Todea superba* and *T. pellucida* in 3-in. pots when bought seven years ago were planted in this case; the first is now making fresh growth, the old fronds are 21 in. in length, and the plant measures in width 3 ft. 6 in. *T. pellucida* is 6 ft. across and has fronds slightly over 3 ft. in length; the Killarney Fern, of which there is a large mass, has fronds 15 in. in length. I have also a patch of *Hymenophyllum tunbridgense* thriving remarkably well. Any one following the mode of culture just alluded to will have no cause for regret as regards want of success.

Fitroy Park, Highgate.

R. B. FULLER.

Forced Sweet Brier.—In the open air Sweet Brier generally presents a harsh, rusty appearance, until new growth has made some progress in June; but it is one of the easiest plants imaginable to force in pots, and as it is not so liable to the attacks of insects as other kinds of Roses, it may be brought forward in quantity in Peach-houses without incurring much risk or adding much to labour or expense in the way of fumigating. Early in the season, when flowers are scarce, a quantity of fresh young shoots of Sweet Brier as a base or cushion on which to arrange them will be found of great advantage, especially for setting up short-stalked flowers. Plants of the Sweet Brier are usually plentiful enough in the hedgerows in strong soils, and may easily be identified, even when leafless, by the abundance of their spines. Autumn is the best time in which to obtain them, although they may be lifted and potted at any other period, even in summer, if there be the means of keeping them close and shaded until they have become established. Of course the head would require to be cut back into shape in order to balance the untitled roots. Plants of Sweet Brier may also be raised from seeds or cuttings.—E. HODDAY.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Dactylis elegantissima.—This though hardy is a desirable Grass for vases or conservatory decoration. Its leaves are produced in an abundant and graceful manner, and being of a rich golden colour with bright green stripes, they are, when produced by a healthy well grown plant, highly effective.—S.

White Lilacs without Darkness.—Recent experiences go to prove that white Lilacs may be produced in a warm house not darkened, as has been the custom. The heat is supposed to bring out the flowers too quickly for the reddish pigment to be developed. We have recently seen a beautiful Lilac flowering in M. Carrière's house, and which had not been submitted to a higher temperature than that of an ordinary living room.

Vanilla aromatica.—A plant of this in Mr. Terry's collection of Orchids at Peterborough House, Fulham, bore about 100 pods of fruit last season, and of these many were much larger than those that are imported from the East Indies. The Vanilla grows best in a fresh open compost of turfy loam, nodules of peat and freshly-burnt charcoal, sandstone grit, and living Sphagnum Moss. A gentle bottom-heat of 75° or 80° below the pots induces a most vigorous growth, and weak liquid manure may be given once a week with advantage.—B.

Mikania scandens variegata.—This variegated form of the well-known German Ivy is well worth cultivation for covering walls or training up pillars in conservatories, or for overhanging edges of vases. As an indoor plant, too, it will be found very valuable, either as edgings for window boxes or as a pot plant. Its bright, glossy, green and yellow leaves render it very effective, and it is easily kept clear of dust. It is grown in the Pine-apple Nursery for furnishing, a purpose for which it is considered to be well adapted.—S.

THE LIBRARY.

GARDEN RECEIPTS.*

THIS is the complete collection of garden receipts gathered together with great care for THE GARDEN by Mr. Quin. All familiar with a garden know that one of the chief cares therein is combating the various insects and other pests that infest it. Without clear knowledge and continued attention in this way much of the labour and expense devoted to the garden will be thrown away. The object of this book is the collection, in a handy form, of information on this and other topics embraced under the general heading of "Garden Receipts." Great pains have been taken to make the collection in every way as complete as possible. A variety that are sometimes given for one purpose, is justified by the fact that one remedy easily applied in a given district may be too expensive in another; and by the extreme difficulty of getting rid of many of the pests alluded to in these pages. The glossary of the materials used is made a special feature, and is as complete as possible. Although the arrangement of both the receipts and glossary is alphabetical, a copious index has been added to facilitate reference. It is the most useful book for the garden that has been published for some time, being convenient in size, easy of reference, and full of information brought down to recent times. Every one practically interested in horticulture should have it, if only for the sake of saving time in asking questions and in making references.

VAN HOUTTE'S "FLORE DES SERRES."

AFTER an interval of more than a year, caused doubtless by the death of the distinguished editor and head of the firm, the first quarter of the twenty-second volume of this beautifully illustrated horticultural work has at length reached us. The new editor is M. J. E. Planchon, Professor of Botany at Montpellier, and the illustration of the work quite equals that of former volumes. The parts now before us contain beautifully-executed double plates of *Pritchardia pacifica*, one of the beautiful fan-leaved Palms; *Alsophila glauca* (Seemann) or *contaminans* (Wallich), also known as *Chnoophora glauca*, *Cyathea glauca*, and *Polypodium contaminans*, a magnificent Tree Fern from the Indian Archipelago; *Lilium neilgherriicum*, from India; *Bolbophyllum Pahudi*, an extraordinary-looking Orchid from Java, also known as *Cirrhopetalum Pahudi* (De Vriese); the fringed *Pelargonium Captain Raikes*; the variegated stove fine-foliaged plant *Ficus Parcelli*; the white-flowered stove Amaryllid *Hymenocallis adnata* or *litoralis*; the beautiful hybrid Slipper-plant *Cypripedium eurynardum* reproduced from the "Floral Magazine," where it was figured in November, 1875, under the designation of *C. hybridum*; the hybrid hardy *Rhododendron Hippolyte Vande Woestyne*, a seedling of the establishment; the fine, double white, fringed-petaled Indian *Azalea*, raised by Herr Schulz, and named by him *imbricata*; and *Coleus Duchess of Edinburgh*; also single plates of *Ixiolirion Pallasii*, an exceedingly pretty hardy bulb with blue flowers, from Turkestan; *Habranthus hesperus*, an ornamental, deep red-flowered Amaryllid from Chili; the handsome *Iris* from China and Japan, known as *I. tectorum*, or *tomiolopha*, or *cristata*, with large, deep blue flowers; the fine, dark, Hybrid Perpetual Rose *Senateur Reveil* (Damaizin); and the Brazilian Orchid *Cattleya Schilleriana*, called also by some authorities *Epidendrum Schillerianum*; in all, eleven double and five single plates, very good value for what the numbers cost.

W. E. G.

A Derbyshire Clergyman on Vegetable Diet.—Speaking at a vegetable banquet at Leeds the other day, the Rev. C. H. Collins, of Wirksworth, Derbyshire, said he was descended from a long line of gouty ancestors, and he owed to vegetarian diet a new lease of life. He had also been a sufferer from gout, but he had driven it out of his body entirely by pure and wholesome living. Having become more than ten years ago a total abstainer, and having not long afterwards become a vegetarian, he had gradually driven the gout out, and could give no other reason for it except total abstinence from alcoholic liquors, and total abstinence from flesh meat. He considered that the teeth of man showed that he was not carnivorous but frugivorous, and he claimed for the vegetarians that they were acting according to the laws of Nature. The stomach, he contended, also showed that it was intended not to receive flesh but the fruits of the earth. He would not go back to his former mode of life for anything that could be given him. They knew that vegetarian diet agreed with the delicate as well as the robust, and that it was a wholesome and enjoyable mode of life.

* "Garden Receipts." By C. W. Quin. London: Macmillan & Co.

STAR-LIKE HAIRS ON PLANTS.

It is generally known that the stems of herbaceous plants, and particularly the leaves, are often covered more or less thickly with long or short hairs of a softer or harder consistency. Sometimes these hairs are isolated, straight, and pointed like a needle; sometimes they become ramified, and resemble a stem with its branches; others coming from a common centre and following as nearly as possible in the same direction, form a brush; others again, stretching themselves out in opposite directions, form a star. These are particularly curious and often beautiful to observe. In the fine herbaceous plant with yellow flowers called *Onosma tauricum*, these

Fig. 1.—Hair of *Onosma tauricum*.

hairs are visible to the naked eye, especially those on the lower sides of the leaves, but the use of the microscope is necessary to reveal all the beauty of them. When they are examined through the aid of this instrument, it is surprising to see their transparency as if composed of the purest crystal—one might call them diamond stars. At the base of each branch of the star is remarked a white protuberance, slightly opaque, and the branches themselves are formed of irregular stumps gradually becoming smaller and terminating in sharp points; the one in the centre being much longer than the others, and

Fig. 2.—Hair of *Alyssum alpestre*.Fig. 3.—Hair of *Alyssum montanum*.

holding itself perpendicularly on the surface of the leaf. This star is represented by fig. 1. Fig. 2. gives us a good idea of the star hairs found on the leaves of *Alyssum alpestre* (the Golden Basket). In it the small star is stretched out, while it retains a regular form. The branches are knotty and of a crystalline appearance, the same as in *Onosma tauricum*. These hairs give the leaf a silvery and velvety appearance. The hairs of *Alyssum montanum*, although at first sight resembling the preceding ones, are very different when seen under the microscope. The star is composed of eight arms; these are again divided into two or three branches, which render it irregular and tufted. In another variety, *Alyssum spinosum*, the hairs are much shorter, thicker, and the rays far more numerous. L. M.

Fig. 4.—Hair of *Alyssum spinosum*.

TREES AND SHRUBS.

THE YEWS.

By GEORGE GORDON, A.L.S., Author of "The Pinetum."

The Common Yew (*Taxus baccata*).—There are great numbers of varieties of the Common Yew, some with green leaves, some with variegated ones, and others with erect branches and with prostrate ones. The most striking of the green-leaved varieties are the Irish, the Dovaston, and the Yellow-berried, and of the variegated kinds, elegantissima, Barroni, and the varieties of the Irish and Dovaston. The Golden Yew grafted on the Irish one has a fine appearance in a mixed shrubby border, into which it infuses a little colour at a season when it is most wanted.

The Adressed Yew (*Taxus adpressa*).—This forms a very distinct plant with short, adressed leaves, numerous, much divided branchlets. It is a low, dense bush, 5 ft. or 6 ft. high, and is a native of the mountains of Japan.

The Indian or Assam Yew (*Taxus Wallichiana*).—This kind, according to Major Madden, in his "Observations on the Coniferous Plants of Northern India," is very common in the British Himalayas, Nepal, Sikkim, and Cashmere, and is found at from 8000 feet to 10,000 ft. It forms beautiful forests and attains a large size, sometimes 15 ft. in girth, furnished with numerous twiggy branchlets, and leaves very similar to those of the Common Yew. Dr. Royle says that in Kamaon Tea is made from the leaves and young shoots, which are gathered from July to October, and after infusion in hot water are rubbed over with a thin solution of gum and dried in the sun; the first infusion is reddish and reckoned heady, but the second which is used is yellowish-green. He also says that the leaves are exported to the plains, where they are much used in native medicine. It is the *Taxus virgata* of Dr. Wallich, and called "Dheyri" in Nepal, where the green branches are used to adorn houses during certain festivals; the decoction of it is freely drunk at Simla, and called "Singcha," as a remedy for rheumatism. It is quite hardy.

The Canadian Yew (*Taxus canadensis*).—This is a low-spreading bush, having leaves of a brownish hne. It is a native of Canada, Maryland, and the Rocky Mountains, in shady places.

The Western Yew (*Taxus brevifolia*).—This forms a tree 30 ft. or 40 ft. high, with a stem which frequently girths 4 ft. or 5 ft. It is a native of N. California, where it is found growing on the sides of glens under the shade of large trees. It differs but slightly in appearance from the Common Yew.

The Cuspidate-leaved Yew (*Taxus cuspidata*).—This forms a large bush, densely clothed with somewhat ascending branches and dark green leaves. It is a native of Japan, where it grows from 15 ft. to 20 ft. high.

Black Italian Poplar (*Populus monilifera*)—This is well known to be one of our fastest-growing forest trees, the timber of which is much used in constructive work, where toughness and moderate elasticity combined are required. The tree is a native of North

America, and is said to have been first brought into Italy, and thence to Britain; hence the common name "Black Italian Poplar." It was first introduced into this country from Canada in 1772, and London, in writing of it some half-a-century ago, says:—"Its rate of growth in the climate of London, in good soil, is between 30 ft. and 40 ft. in seven years, and in Scotland it has attained the height of 70 ft. in sixteen years." Such rapid growth it is not likely to make in all cases, but there is a growing knowledge of the usefulness of the timber and the profitableness of the tree as a forest crop, and we have every confidence in recommending it to the attention of planters as a most valuable tree where the soil and climate are suitable to its nature. In corroboration of our opinion we have much pleasure in quoting the following letter from Mr. McLaren, forester to the Earl of Hopetoun. He says:—"A Black Italian Poplar, containing 80 cubic ft. timber, was cut down last December. It was planted in 1824, in a

mixed plantation of Ash, Elm, Oak, Maple, Poplar, Larch, and Scotch Fir; and after being cut down was sold at our public sale for £8 12s. 6d., being more than double the price received for any of the other kinds at the same age; the Larch approached nearest to it in size and the price per tree which it brought. It may be said that the soil suitable to the free growth of the Poplar does not suit the other sorts, but while it was planted in a damp spot peculiar to its healthy growth, the others were planted upon higher and drier ground, more congenial to their nature, so that they were upon equal terms in that respect. Another thing in favour of the Black Italian Poplar is, that from its upright habit of growth it can afford to stand closer upon the ground than any other common hardwood tree, and it requires little or no pruning, naturally forming a straight and clean pole. It would be no great stretch of imagination to suppose that a Scotch acre would produce seventy trees worth £5 each in fifty years, which would yield a rental of £7 per acre per annum for that period, the thinnings and periodical cuttings having already paid the cost of planting and management. Many of the Poplars are beautiful trees as regards colour in autumn—more beautiful even than the Mountain Ash. In the case of the White Poplar, for example, half of the foliage is often a fine yellow while the rest shows all manner of weaker tints of that and other colours, and the same holds good in reference to other kinds. In addition to their beauty, Poplars make excellent

screens for the windy sides of gardens.—"Journal of Forestry."

Upright or Irish Yew.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Best Time for Clipping Ivy.—I had my Ivy on the house clipped about the middle of April. This is too late, as the young shoots are too strong to allow of its being brushed after clipping, a necessary operation on account of the dirt and dead leaves. My experience is, clip Ivy if you wish to keep it clean in March.—J. H.

Variiegated Japanese Honeysuckle and its Uses.—In addition to the ways of employing this Honeysuckle enumerated by "R. M." (see p. 329), allow me to say that it also makes a grand bush for lawn planting; of course it should be kept clipped, or pinched in so as to induce compact growth. I have in my mind's eye a splendid bush of it which is growing on the lawn in the late Canon Kingsley's garden, of which you give an illustration on p. 91 of the present vol. of THE GARDEN. In the picture the plant is shown on the right of the open door of the late Canon's study.—W. W. H.

THE FRUIT GARDEN.

GUMMING IN PEACH TREES.

THIS disease affects other stone fruits besides the Peach, but it is most to be dreaded in the case of the latter. Fortunately, it does not occur very frequently; but under some circumstances it is very troublesome and difficult to contend with. I have known trees to be quite ruined by it. As has been stated by others who have written upon the subject, when gumming affects Peaches to a serious extent there is no cure for it—prevention is the best plan. Gum is described as extravasated sap, or sap forced out of its proper channels. In the Peach it appears in small sticky lumps or globules, both upon the young and the old wood, oozing through cracks or wounds in the bark, and very often when a shoot has been cut back, particularly if it have been strong and ill-ripened. When the gumming continues, the wood decays, and very frequently the branch dies off altogether. In cases where the disease appears to originate spontaneously, as it sometimes does, appearing in different parts of the tree at the same time, ill-ripened wood and pruning combined are usually the cause. At first nothing appears to be wrong; but, after growth commences, the gum will be found exuding just where the cut was made, and particularly on those shoots which have not been shortened back close to a bud. In such cases the wood above the bud dies back to that point, and the gumming begins at the junction of the dead and living tissues, and if not arrested will extend down the limb, and sometimes kill it. Indeed, the gumming sometimes begins a considerable distance below the cut, causing the young shoots to break weakly; and the best plan then is to cut still further back to where the wood appears to be sound and the young growths healthy. In trees predisposed to the disease the least injury will produce it—such as too tight a tie, a scratch with the knife, or an abrasion of the bark from any cause. I have known two-year-old wood to die off through gumming brought on simply by contact with the wire. Galvanised wire trellises have been known to produce gumming in an aggravated form on trees grown out-of-doors, and a number of instances have been recorded. A case of that kind occurred some years ago that is worth referring to. Four Peach and Nectarines trees, on which gumming had not been observed before, were removed to a warmer wall, and trained to a galvanised wire trellis. They were pruned in February and tied loosely to the wires, and nothing was observed to be amiss with them till rather late in the season, when it was found that gumming had broken out on the whole of the trees at those places where the shoots touched the wires. The latter had killed the bark and wood where they came in contact with them, and gumming was the consequence. Be that as it may, the disease was very destructive, and crippled the trees seriously; but it did not extend much after a wooden trellis was substituted for the wire one. In another case the gumming was clearly traceable to an ill-ripened condition of the wood. The second year after planting, a vigorous-growing Royal George Peach in the Peach-house began gumming where the maiden shoot had been pruned, beginning first at the cut, and going down one side of the branch. The wood was not as well ripened when planted as could have been desired, and some time afterwards I noticed that the wood was black and discoloured round the pith of the limb in question. The decay extended towards the outside, and there the gumming appeared. Being anxious to save the limb, I cut away all the diseased side nearly into the pith, but could not get out all the black heart without cutting the limb nearly through. The consequence was that the gumming appeared the next year, and the next, as bad as ever. By this time the branch was a good size, and formed a main portion of the tree, for, although it was weaker than the other branches, it continued to grow pretty freely. As a last resource, therefore, I took a joiner's small gouge, and, after cutting off the external gummy portions, I bored the black and decayed heart-wood out, and then filled the whole, which was about 3 in. deep, with white lead. After that the gumming ceased, and the branch is still alive and healthy; but though the operation was performed ten years ago, the effects of the gumming are still noticeable. And now as regards prevention and cure: the latter, as has

been hinted, is out of the question in bad cases; but when only one or two shoots are affected, cure is not to be despaired of, and the best plan is either to remove the diseased shoot altogether, or the diseased part, as soon as it is observed, and to encourage new growth so as to provide an outlet for the sap. When the disease affects the trees generally, and seems to be constitutional, the only plan is to lift the trees and replant in a not over-rich and rather hard soil, which will restrain exuberant growth; and if at the same time the trees be trained thinly, it will contribute towards the same end, and the better ripening of the wood. Pruning, in outside trees at least, should be deferred till February, and the shoots be cut back to where the wood is mature, as will be indicated by the forwardness and plumpness of the buds; but later in the season the trees should be looked over again, and the weakly and suspicious-looking shoots removed. In training, the utmost care should be exercised, to prevent injury to the bark by tying the shoots in too tightly, or bruising them with the hammer or nails. Neither is it advisable to tie the young growths in too soon, but better to let them grow out from the wall, till they are 12 in. or 13 in. long, and then one tie about the middle will suffice to hold them in their place; the growing point should always have freedom. At the same time tying in should not be delayed till the summer is on the wane, otherwise the ripening process will be retarded, and the evil encouraged that it is sought to prevent.

S. W.

SERPENTINE WALLS AND FRUIT CROPS.

ALTHOUGH these are not likely to supersede straight walls, there are some exceptional situations where a waved or serpentine wall would be decidedly preferable to a straight uniform line of brickwork, for when the kitchen garden is bounded by, or in conjunction with, the pleasure grounds, a wall of this description may be much more easily disguised or screened than if straight. Most of our walls on the outskirts of shrubberies here are built in this way, and although exposed to the full force of our strong easterly gales, they offer such a strong resistance owing to their shape, that 9-in. brickwork, without any strengthening or support in the way of piers or buttresses, is apparently immovable, even when carried to the height of 12 ft. They are for the most part overgrown with the common English Ivy, which is annually laden with berries, and which looks far better than when clipped in close; moreover, as great quantities of the best berried pieces are cut out for Christmas and other decorations, the remainder never gets top-heavy or breaks down. We have a long wall built in this form 12 ft. high with an east and west aspect, entirely devoted to Pears trained horizontally, and as the recesses offer a gradual curve of 30 ft. one tree is planted in each, giving 15 ft. each way for the branches to extend, and as they meet on the most prominent part of each projecting portion of the curves, a very interesting way of breaking the monotony of a fruit wall is to plant a Rose or any climbing plant against this portion and train it up as a single cordon to the wall, allowing the annual growths to extend in a natural manner. These prominent points treated in this way entirely alter the character of the ordinary aspect of fruit walls. The serpentine form of walls is not only well adapted for withstanding the effects of strong gales of wind, but the recesses offer a considerable amount of shelter to the trees growing on them, as the current of air cannot sweep so uninterruptedly along the face of them as along a straight line. The curves may be more or less sharp according to the purpose which they are intended to serve, but if used for fruit trees, a very gradual curve is the most desirable; ours deviate from the straight line about 1 ft. 6 in., giving a curve of 3 ft. between the two extremes. The principal objection to this kind of wall is that copings or roller blinds cannot advantageously be employed for the protection of tender blossoms during the critical stages of flowering, when spring frosts are both prevalent and destructive; but as the earliest-flowering of our fruits, such as Peaches and Apricots, are usually grown on south aspects, there is no lack of wall trees that flower at a later period for which the wall itself should prove an efficient protector, if the bearing wood be trained close enough for the blossoms to receive at night the benefit of the latent heat absorbed by the

brickwork during the day, and where it is desirable a temporary protection in the form of fish nets, tiffany, evergreen branches, &c., can be as readily fixed on this kind of wall as in the case of any ordinary straight one.—J. GROOM, *Ilchenham*.

DEVELOPMENT OF THE AMERICAN FRUIT SUPPLY.

For over a quarter of a century American Apples have been exported to this country, although not in large quantities. The great obstacle to the trade was the difficulty in the ocean transportation. Fruit that would keep well in America for many months would, it was found, rapidly deteriorate when barrelled and stowed away in the hold of a steamer, even during a short voyage across the Atlantic. The only variety that possessed the necessary keeping quality was the Newtown Pippin; but, as this Apple was expensive, and in some years inferior in quality, comparatively small shipments were made of it. Experiments were, however, successfully made with other varieties, such as Greenings, Baldwins, Spitzenbergs, and a few others, and shipments of them were more or less financially successful. Still, the total amount of the trade for six years previous to 1875 was comparatively small. In that year, however, our crop of Apples was a failure, while those of the United States and Canada were extraordinarily large. The shipments made to this country were greatly in excess of those of the ten previous years together, and, from the low prices of Apples in America, and their high price here, money was made by the shippers. Hitherto, whilst our orchards yielded fairly, the demand for American Apples has been light, but the failure of our Apple crop last season, with an abundant one in America, has given a new impetus to the trade. During the past winter it was placed on a more systematic and permanent basis than it has heretofore occupied by a New York house, dealing largely in American products. One of the firm has spent this winter in England, attending to the reception and disposal of the consignments of fruit; while the other has attended to its selection in America, its packing and shipment. The results so far are said to have been most successful, and this trade—which, from its precarious nature, has hitherto been regarded as a series of hazardous ventures—is now put, for the first time, on a business footing. From the middle of October until the end of March, almost every steamer arriving from America brought over shipments, varying from 500 to 3000 barrels. No fewer than 90,000 barrels of Apples were landed in December at Liverpool alone, supplying chiefly the markets of the metropolis, and those of Manchester, Birmingham, Hull, and Bristol. On account of its good quality and superior condition in which it arrived, the fruit has found much favour with consumers. Its abundance has kept down the prices of Apples to such a figure as to extend their consumption. During cold weather but little difficulty is experienced in shipping fruit to this country from America. With the advent of warmer weather, however, greater care is required for its protection during the sea voyage. This involves several important considerations—having reference to the period of ripening at which the fruit is plucked, its preservation previous to packing, the packing itself, and then the method of stowage on board of the steamers. It is well known to those acquainted with the growth of Apples that there is a time when their growth is completed, when they will receive nothing further from the tree. Soon after they reach that stage the after-ripening begins in a chemical change through which the starch, so abundant in green fruit, is transformed into sugar. When this transformation is complete the fruit is in the best condition for use. Almost immediately after, however, putrefaction sets in, first dissipating the volatile aroma and destroying all delicacy of flavour, finally converting the sugar into an unwholesome acid, and consuming the tissues of the fruit. A low temperature and a dry atmosphere may sometimes retard this change; yet its progress is so easy and rapid that efforts to preserve the fruit after it has become ripe are of little avail. But the progress of the first change may be so delayed as to require several months for its accomplishment. It is only necessary for this purpose to take the fruit from the tree at the moment of its maturity, and to keep it in a low even temperature and dry pure atmosphere, secluded from light. In many of the American Apple-growing regions fruit hives are constructed where these conditions are almost secured to perfection—in which, for instance, the thermometer does not rise above 34° for months together, and fruit kept in them barely ripens in time for the late spring market. The Apples received from New York are chiefly grown in the Niagara district, and in Wayne and Orleans counties. Those shipped from Canada are principally from that portion of the province of Ontario lying on the north side of the lake from which it takes its name. Several choice varieties, however, such as the Pomme Grise, Fameuse, and St. Lawrence, are grown on the island of Montreal. New England

Apples find their outlets at Boston and Portland, and, although somewhat inferior in quality to the New York and Canadian fruit, have been well received, and sold rapidly, although at lower prices. Like everything else in America, the fruit-producing resources of the country are enormous. In 1875 there were no less than 4,500,000 acres in orchards in the United States alone, and about 274,674 acres in the Dominion, of which 207,011 were in the province of Ontario. The shipments in Apples from the United States in one year amounted to no less than 1,185,803 barrels; while the value of what was used in home consumption was £600,000. The total yield of the Canadian orchards in one year was no less than 2,121,772 barrels.—“Field.”

FRUIT TREES IN POTS & TREES ON TRELLISES.

T. F. R. (see p. 379) states that his Peach trees, planted out and trained on trellises under glass, do not set their fruit so well as those in pots. We are not told whether the houses in which they are grown are heated or unheated; but, from a very lengthened experience in Peach growing, both in pots and on trellises, I have always found those, planted out and trained on trellises, to set plenty of fruit even in unheated orchard houses. During the late severe frost in the first week in May I had a glass-covered south wall of great extent, with Peach, Nectarine, and Apricot trees planted out in the borders, and the trees are covered with young fruit, and not starved with the cold. In both heated and unheated houses this year all the Peach trees planted out and trained on trellises are producing full crops—at least all that have come under my inspection. Last year, owing to the almost tropical heat in July and August, the wood was thoroughly ripened, and showed abundance of healthy bloom. Indeed, all kinds of fruit trees this year never showed more promising signs of good crops, and if the late cold easterly winds and frosts have slightly thinned the young fruit there will be plenty left. “T. F. R.” says his orchard-house has been erected twenty-seven years, but he does not tell us how many of the pot trees which he commenced with have succumbed to old age and barrenness. I do not at all deprecate the culture of fruit trees in pots, for they are a source of great enjoyment to amateurs and usefulness to cultivators who have but a limited quantity of glass houses. The orchard-house system will, however, never be a profitable one as far as regards growing the trees in pots, for the great supply of fruit for market will be derived from trees planted out. The finest specimens of fruit of Peaches and Nectarines, either for dessert or exhibition, can only principally be gathered from trees planted out and trained on trellises, or from bushes or pyramids when planted out. Unless the trees are grown in pots of a large size, no amount of stimulants will swell the fruit to the size which they attain when the trees are grown in the borders, and neither in colour nor flavour will they compare with well-grown border fruit. W.

TALL-GROWING ORNAMENTAL GRASSES.

PAMPAS GRASS.—The Pampas is perhaps the most useful and effective of all Grasses for introducing extensively into wild coverts; it succeeds well in such situations, and is highly ornamental in autumn, when but few flowering plants are visible, lightening up as it does and contrasting beautifully with dark Evergreens. To give the best effect it should be planted in groups of three, five, or more plants in proportion to the surrounding space; single specimens may be planted in suitable nooks where the space is more limited. The upright Silvery-plumed Grass is to my thinking the best and most striking variety, and one which retains its beauty for a much longer period than any other. The rose and claret coloured Pampas Grasses are the handsomest and most showy of the forms with a drooping habit, but unless their stems be supported by means of stakes and string, they are almost certain to get broken down by strong winds before the whole of the beautiful panicles are fully developed. Sites sheltered from prevailing and cutting winds should be selected for them in front of evergreen shrubs, or backed up by sombre-foliaged trees, but at the same time a light and airy situation with a rich soil and porous subsoil is the one in which they succeed best. After the selection of the places for the plants or groups, the ground should be turned up to a depth of from 15 in. to 18 in., and a cart-load of rich soil, road-parings, or loamy turf should be allowed to each plant, and well stirred in amongst the original soil; a thick mulching of manure should be spread on the surface after planting, and if the weather be dry a

thorough soaking of water will be necessary. Pampas Grass is benefited by being planted on slightly raised mounds, on which it shows itself off to better advantage than when placed on a level surface. Strong well-established plants treated as above are almost certain to succeed. If ground game abound, wire netting should be fixed round to protect the young plants for a year or two after planting, for when the Pampas is thoroughly established these mischievous animals rarely do it any injury; on the other hand, if small weakly plants be put out in coverts, and not sufficiently protected at first, they are almost certain to prove disappointing to the planter, either through hares and rabbits devouring them, or through want of sufficient soil in which to grow vigorously and develop strong flower-spikes; the Pampas is a grass-feeding Grass, and the richer the soil the stronger and more numerous will be the flower-spikes. Even after the plants have been established in their permanent quarters, they will derive great benefit from a covering of leaf-mould or other enriching material being spread over the surface around each plant every autumn.

ARUNDO CONSPICUA.—This is another fine ornamental plant, though not quite so hardy as the Pampas Grass, and scarcely so vigorous a grower, but none the less graceful on that account. It has one advantage over the latter by coming into bloom a

The great Reed (*Arundo Donax*) in flower.

month or two earlier, and in consequence its graceful inflorescence is not so liable to be destroyed by rough winds and wet weather; while unfortunately the Pampas Grass does not open its flowers until bad weather has generally set in. In the southern and western counties this giant Reed stands the winter without protection, but further north it is not likely to succeed so well, unless some protecting material be used to ward off severe frosts.

ARUNDO DONAX.—This very desirable tall-growing Reed is strikingly effective when associated with a pond or stream of water; it also shows itself off to great advantage in pleasure-grounds amongst low-growing shrubs. A variegated form of it can be had of a still more ornamental character; but it is not so hardy and it is less vigorous in growth. The above *Arundos* should receive the same treatment as regards planting as the Pampas Grass; but a little more protection will be necessary to keep them alive during very severe winters, especially in the northern counties, or in low-lying damp situations; a rich soil and a porous subsoil on a dry, slightly raised site is the most suitable position in which to ensure healthy and strong plants capable of withstanding severe frosts.—G. B., in "Journal of Forestry."

PLATE LXXV.

HARDY AZALEAS.

(WITH A COLOURED FIGURE OF *A. MOLLIS*.)

By W. B. HEMSLEY.

WHETHER we regard the Azaleas as constituting a genus distinct from *Rhododendrons*, or as only a section of the latter, there is no difficulty in distinguishing the cultivated hardy species and varieties from the *Rhododendrons*; consequently, it is convenient and useful to keep them separate here, although there are species not in our gardens which unite the two groups both in structure and external character. All that come within our province are deciduous shrubs, which put forth their flowers before the leaves, or the leaves and flowers are developed simultaneously, and the flowers of nearly all the species and varieties have only five stamens, whilst true *Rhododendrons* are evergreens, with more numerous flowers in the clusters, and ten or more stamens in each flower. Broadly speaking, Azaleas and *Rhododendrons* have the same geographical distribution, with the exception that no true Azalea has hitherto been discovered in the mountains of India. In both cases we have a single species from South-eastern Europe and Asia Minor, and several from North America and Eastern Asia represented in our gardens. Azaleas may be classed in the first rank of deciduous shrubs cultivated for the sake of their ornamental flowers; yet, notwithstanding the beauty and variety they present, they are comparatively neglected. Amateurs having small gardens and limited means are deterred from planting them, probably because they are usually described as peat-loving plants. It is true that they attain greater perfection in a carefully-prepared soil than they do in a close, adhesive soil; but in this respect hardy Azaleas are less exacting than most *Rhododendrons*, and will flourish in places where *Rhododendron ponticum* grows freely. It is worth noting that most of the hardy Azaleas grow naturally in swampy places, but not necessarily in boggy ground. But the hybrid varieties commonly cultivated succeed well in light, thoroughly-drained soil. In the absence of peat, leaf-mould may be used, and where the soil is heavy sand should be added. Of course, the proportions of leaf-mould and sand necessary or desirable depend entirely upon the nature of the soil upon which one has to operate; and a light, porous soil requires no modifying. Planted singly or grouped, Azaleas are very effective, but they are not so well suited for mixed shrubberies, nor do they grow and flower so freely when mixed with other subjects. For the variety and brilliancy of their usually fragrant flowers they are unrivalled, and many of the tints and shades of colour are almost unknown in any other class of plants. They range through all shades and hues of yellow to orange and red to crimson, with some very singular mixtures of yellow and red; there are also white-flowered varieties. Another strong point in their favour is that they produce their flowers soon after the beauty of spring-flowering shrubs is past. Being slow-growing subjects, they should be planted rather thickly, for they are some years growing and spreading 3 ft. or 4 ft. Besides the true Azaleas with deciduous leaves, there are some hybrids between them and some of the *Rhododendrons*, especially between *R. ponticum* and *A. sinensis*. The hybrid called *R. praecox superbum* has the flowers of an Azalea and the persistent leaves of a *Rhododendron*. The following species or wild forms have given birth by intercrossing and natural variation to the numerous varieties now in cultivation; but the North American ones especially are very variable in the wild state, and it is difficult to characterize them.

Turkey Azalea (*A. pontica*, Bot. Mag., t. 433).—Although this species is much nearer to us, it does not appear to have been cultivated in British gardens so early as some of the American species. According to Aiton ("Hortus Kewensis") it was first introduced by J. Bell, Esq., in 1793; and in the Bot. Mag., under the plate quoted above, it is stated that Antony Hove, Esq., of Warsaw, introduced it in 1798. In the same place some interesting extracts, from the diary of the gentleman named, respecting its distribution will be found. It is a native of Asia Minor, chiefly in the countries bordering the Black Sea from the Caucasus westward, and also in south-eastern Europe along the valleys of the Dnieper and Dniester. It

THE DOWNY AZALEA A. MOLLIS-REGEL

occurs some distance inland, and Mr. Hove also saw it growing in thousands in a marsh, which was often overflowed by the sea. Under favourable conditions it rarely exceeds 6 ft. in height, and is usually much smaller. It differs essentially from *A. sinensis*, with which it agrees in having typically yellow flowers, in the corolla being funnel-shaped, with a long, narrow tube, and hairy outside, and in the leaves being hairy on the margin only, or very slightly hairy on the surface. The plant figured in the Bot. Mag. was grown in heat in the nursery of Mr. Watson, at Islington.

Japanese Azalea (*A. japonica*, A. Gray).—The most familiar variety of this species, that having yellow flowers, was first introduced into this country from China, and this was the cause of its being named *A. sinensis*; and this name is retained by Maximowicz in his monograph of the "Rhododendrons of Eastern Asia," although the plant does not appear to be a native of China. Several other names have been given to slight varieties, probably of garden origin in China or Japan; indeed, although the species was originally introduced in 1824, it was so imperfectly known that when Maximowicz introduced, in 1863, a variety differing from the type in having orange-coloured flowers under Blume's name of *A. mollis*, it was not identified, I believe, until he himself elaborated the whole of the species of the genus *Rhododendron* (including *Azalea*) in 1870. Messrs. Loddiges & Son introduced it from China into this country, through what agency it is not stated; Fortune again sent it to England about the year 1843, but it seems never to have spread very widely. Probably now that a new strain of varieties of this very distinct species is gradually increasing in numbers and variety, it will become more popular. The most striking cha-

characteristic of the varieties of this species among hardy Azaleas is the campanulate corolla, more like that of a true *Rhododendron* or *Azalea indica* than the Turkey or American species. The flowers appear before or with the leaves, and are almost scentless. It would be worth while trying to raise some hybrid varieties between this and the American species in order to combine the fragrance of the latter with the greater beauty of the former. Maximowicz gives the native habitat of this species as the Alpine mountains of the island of Nipon. There are several other species, natives of Japan, which would doubtless prove hardy in this country, but none of them equal in beauty the varieties of the present species.

[Synonyms—*A. sinensis*, Lodd., Bot. Cab., t. 885; *A. mollis*, Bl.]

Tree Azalea (*A. arborescens*).—A shrub or miniature tree, from 3 ft. to 10 ft. high, according to circumstances; branches and leaves quite smooth, the latter glaucous on the upper surface, and furnished with bristly hairs on the margin; long calyx-lobes and a slightly clammy corolla characterize this species. The rosy-red flowers are very fragrant, and appear after the leaves are developed. A native of North America, in mountainous districts, from Pennsylvania southwards. Introduced into this country in 1818, but it has probably had little share in the parentage of garden varieties.

Clammy Azalea (*A. viscosa*).—This is the swamp Honeysuckle of the Americans, and differs from the last in having bristly shoots and midribs of the leaves, in the calyx-lobes being very small, and in the corolla being very clammy, with a tube much longer than the lobes. The flowers appear after the leaves, and vary from white to rose. Introduced by Peter Collinson in 1734.

Pinxter Azalea (*A. nudiflora*).—In this and the next the flowers appear before or with the leaves, and this especially is remarkable for the naked appearance of the branches when the clusters of flowers expand at the tips. At the outside, this grows only about 6 ft. high. It has hairy branchlets, leaves downy beneath, very short calyx lobes, and the tube of the slightly glandular corolla is scarcely longer than the lobes. The flowers are very variable in colour, varying in the wild state from flesh-colour to pink and purple. It inhabits swampy ground in eastern North America, from Massachusetts southwards, and was also introduced by Collinson in 1724.

Flame-coloured Azalea (*A. calendulacea*).—This differs from the Pinxter Azalea in its usually larger stature, conspicuous calyx-lobes, and in the hairy corolla-tube being shorter

than the lobes. The large, scentless flowers are yellow-orange, changing to flame-colour. It inhabits eastern North America, from Pennsylvania southwards. *A. occidentalis* (Bot. Mag., t. 5005), from California and Oregon, is scarcely different, except in its white flowers streaked with red and blotched with yellow.

Nepenthes intermedia.—This hybrid, raised in Messrs. Veitch's nursery by Mr. Court, is the result of a cross between *N. Rafflesiana* and an unnamed species with small spotted pitchers. The latter, which are produced abundantly, are large, often exceeding 5 in. in length, with a diameter of 2½ in. at the broadest part. In

Veitch's Hybrid Pitcher-plant.

shape they are, as will be seen, flask-like, slightly narrowed at the bottom, and more contracted at the mouth; the wings are prominently fringed. The numerous reddish-brown spots and flakes and a rim or marking about 1 in. below the mouth are distinctive features of this variety.

THE KITCHEN GARDEN.

CUCUMBER CULTURE IN MARKET GARDENS.

This is one of the most extensively grown indoor crops in market gardens, some growers devoting immense ranges of glass houses to its cultivation, while others grow it very largely in frames on sunken hotbeds. Some idea of the extent of its culture may be obtained from the fact that one grower at Fulham has annually a field containing many ranges of frames with from 800 to 1000 ordinary sashes. From this field are sent to market weekly during the summer from 180 to 220 dozen of fruits. The Telegraph, and varieties of it, are much grown in frames; so is the Syon House, Pettie's, and a few other sorts. These kinds, together with the Rabley, Duke of Edinburgh, Sutton's Perfection, and a few others, are chiefly used for growing in span-roofed and lean-to pits or houses. For framework the first sowing is made in little punnets or flower pots, which are placed in hot-manure frames. When the seeds germinate and are fit for potting-off, two plants are put into a 6-inch pot, and the whole replaced in the frames, keeping them near the glass. About the middle of February, as soon as the frames can be spared, they are moved aside, and trenches cast out 5 ft. wide and 2 ft. deep, and firmly filled with once or twice-turned stable litter. Over this some soil is placed, and the frames set on again. The earth that was cast out of the trenches almost levels up the space between the frames. When the heat is at a proper temperature for planting, a little more soil is introduced to the frames, and one potful (containing two plants) is placed under each sash, and one of the plants is trained towards the front of the frame and the other towards the back. The sashes are then put on and all is kept close for a few days, and, if need be, a little shading is also given by strewing some litter over the glass. Afterwards, until the plants have fairly begun to grow, no more ventilation is given than is necessary to prevent scorching in the case of bright sunshine. Another sowing is generally made to succeed the first one, but, as a rule, there are seldom more than two sowings made, and the second is only sown because all the frames are not empty at one time, to be filled by the first sowing. Where great pains are taken the earliest plants retain their good bearing qualities as long as the latest-sown ones. For several weeks after having been planted they are protected at night by covering the sashes with litter, removing it next morning; indeed, this covering is not discontinued until the month of June. When the plants have grown sufficiently to come into bloom they are most attentively looked after in the way of regulating the growths, pegging down the Vines, stopping the shoots at the joint beyond the embryo fruit, and in preventing an accumulation of superfluous growths. Throughout the day they are allowed to have plenty of air during the summer, but it is all taken off at night; in the morning the sashes are tilted up a little, and as the heat of the day increases the sashes are still further opened. Water is given in the morning abundantly to those requiring it, whilst those that are not dry have simply a sprinkling overhead. It is cold water from the tap that is entirely used, and doubtless this is the greatest drawback to Cucumber growing with which the market gardener has to contend, as where one or several acres are covered with frames, it would be almost an impossibility to make tepid all the water that would be required. Large hogsheads, however, are sunk here and there about the frame ground, and brick or cement tanks are frequently used for containing water, with which they are filled for the next day's use. Guano-water is sometimes given during the summer time, being applied through a fine rose overhead. This application is not only useful as a stimulant, but when given overhead has been found to be of material benefit in destroying or preventing red spider as well as invigorating old plants. In

reference to woodlice toads are put in the frames to destroy them. A couple of men are usually kept at work in the frame ground, and on three days of the week (Monday, Wednesday, and Friday), they are employed in cutting fruits for market, and on the other three week days they are busy stopping and regulating the Vines. Should any young fruits exhibit a tendency to become crooked they are put into cylindrical glasses open at both ends. These glasses are about 12 in. or 15 in. long, and 1½ in. or 2 in. in diameter, and several thousands of them are employed in one large frame-ground, as one good and straight fruit is worth nearly a dozen small and deformed ones. The crooked ones do for pickling. Cucumbers require sunny weather to set well, and in dull wet seasons they do not thrive well, especially in the earlier part of the year. Should the summer be hot and bright, the sashes must be shaded a little, and this is done by strewing some rank litter over the glass; but many market gardeners, by way of economy of labour, paint the sashes with whiting, as in the case of glass houses. By August the plants are getting exhausted; therefore careful attention is paid to thinning out old and bare Vines, and encouraging young wood by means of stimulants, in the way of manure-water and coverings from cold; and in this way they last till September. In August some fruits are saved for seed, for if left sooner they would materially weaken the crop of marketable fruit. Should any "nosed" fruits be detected, they should be tied round with string, and left to ripen, being certain to contain good seed. When the seed fruits become yellow and are cut, they are placed under sashes or on boards before the sun, so as to get thoroughly ripe and hard before being separated from the pulp. In some market gardens narrow span-roofed houses are employed for Cucumber growing, and these are doubtless the best kind of structure for the purpose, but in some cases very roughly-constructed places are used with the best result, for example:—In a village near London there is a small garden devoted to Cucumber growing for market, where the most simple means are employed and the best results obtained. The structures, or houses as they may perhaps be called, are primitive indeed, the first house being an ordinary lean-to against a brick wall, about 20 yards long and 10 ft. wide. In front of this is another of the same length and width, but with a span-roof, also a little glass under the front plate. These structures are low, but to get head-room a pathway is sunk along the middle, perhaps a yard deeper than the ground-level. On either side of this pathway is a long wooden trough from end to end of the house. These troughs are the most noticeable feature of the whole affair; they are of rough inch boards from 2 ft. 6 in. to 3 ft. wide, and 10 in. deep, the soil used being decayed turf full of vegetable fibre, mixed with decayed horse-droppings. The troughs are not quite filled at planting out, and as the mass gets filled with roots, a slight top-dressing, consisting of road-grit and well-decomposed horse-droppings is from time to time applied. The idea is correct, viz. that slight dressings frequently applied maintain health without over-stimulating. The point most noticeable is the small modicum of soil allotted to the plants: they stand about 2 ft. apart; they are grown with straight stems, about 1 ft. or 18 in. long, and trained on temporary trellises, 1 ft. from the glass, which is not far enough, as both cold and sun affect them slightly at that distance. The heat is supplied by means of flues—that is, 9-in. socket pipes put together with cement do duty as brick-flues. A row of these pipes is carried along on either side under the middle of the troughs. In excavating the path the side earth is left; on the top of this run these pipe-flues, almost close to the bottom of the troughs in which the plants grow. This flue is the only source of heat; in severe weather straw mats are put on, and are found to be of great service. The cubical contents of one of these structures is very little; and limited as the surface is, it can readily be covered up to economise the heat given off inside. The plants for bearing all spring and summer are put out in the early part of winter; the object being to have plenty when the demand is good. The quantity of fruit produced in these small houses is something marvellous. They are cut three times a week, and supplied direct to the consumers, only the rough ones are sent to the market for what they will bring. The

sort this grower prefers above all others is Sutton's Perfection. Telegraphs and various other esteemed sorts are grown, but no sort, in his opinion, is equal to Sutton's. The culture of the Cucumber in the open air is now seldom practised by market gardeners in the neighbourhood of London. Many have attempted it, but we believe most of them have now abandoned it, the result not having proved sufficiently encouraging for them to persevere in the matter. Where, however, it is carried on they are grown under glass, and hardened off, and planted out 6 ft. asunder, and 10 ft. row from row, and hand-glasses are put over them. When they begin to grow the ground is well mulched with straw, to keep the earth moist and the fruit clean. Due attention is paid to their subsequent culture in the way of stopping, thinning, &c., and in many cases good results are obtained. In many cases, however, Cucumbers form a somewhat uncertain crop in open fields, some localities being unsuited to their culture; but still, while their produce is in such demand in all large towns, their culture might be profitably extended. At present it is confined to comparatively small spots in one or two counties, the soil and climate of which seem unusually well adapted to their growth. Small, however, as the area at present under Cucumber cultivation is, it is reported to furnish to the London markets not less than 600 tons a week during what is termed the Cucumber season. Of these upwards of 100 tons have been known to be sent to Covent Garden in a single day. They are largely grown at Sandy, in Bedfordshire, and at St. Neot's, in Huntingdonshire. They are packed in square baskets and conveyed by train to the London and other markets. In the neighbourhood of the stations just named Cucumbers are grown by the acre in the open field, many cultivators having as many as ten acres at one time under this description of crop. The soil in the neighbourhood just indicated is, for the most part, a warm, lightish loam or gravel, in every way suited to the growth of this esculent. The ground to be planted is well prepared during winter, and again deeply stirred and otherwise put in good order in spring. The seed is then sown about the beginning of May, where the plants are intended to grow, in rows some 4 ft. apart, and the plants stand nearly 2 ft. asunder in the row. In favourable seasons they soon push into active growth and cover the ground with Vines, which, during the latter end of May, the whole of June, and beginning of July, spread in all directions and come into bearing. During their growth, weeding and thinning their superfluous shoots are well attended to, and if the plants should not entirely cover the ground, or wherever blanks occur, Mangel Wurzel is planted in the vacant spaces. About 4 yards apart are also rows of Onions, set early in the spring, which, being allowed to run to seed, serve in some measure both for shade and shelter. Where Onions are not used for this purpose, Rye, sown in the autumn, 4 yards or 5 yards apart, and cut as soon as the Vines cover the ground, is employed; Peas are also sometimes used for the same purpose. In this way the ground is induced to produce two or three kinds of crops at the same time, and if one should happen to fail, one or more of the others, as the case may be, take its place. By the middle of July or earlier, according to the season, the crop is ready for a first gathering, and from that time to the end of September fruit varying in length from 10 in. to 12 in., green and solid, though sometimes unshapely, is continually being cut, sometimes to the extent of 3 tons at a time, and that from little more than as many acres. What an acre of Cucumbers realises in the way of money we are unable to say with certainty; but they are stated to yield a good profit to the grower, even if he should get no more than 1d. or 2d. a dozen for them. At these prices sums varying from £20 to £60 an acre, according to the season, are said to have been obtained for them. When gathered they undergo the process of sorting, the best being generally sent to London, second-rate kinds to the provincial markets, and what are small, crooked, or discoloured are given to pigs. Ripe ones are saved for seed, so that little or no waste is ever experienced with crops of this kind. The baskets in which Cucumbers are sent to market are called "pads." In shape they resemble those used by wine merchants, *i.e.*, square with hinged lids, and they generally hold about two bushels. It has often surprised people who

think Cucumbers cannot be grown without a frame, how cottagers were able to produce such fine specimens of them as they frequently do at local exhibitions. There is, however, no difficulty in the matter; indeed, the wonder ought to be, that Cucumbers are not more extensively cultivated out-of-doors during summer than they are. The cottager selects the warmest corner of his garden for them. When the spot has been decided upon, two or three circular holes are made, 3 ft. across, and about 18 in. deep. These are filled with garden refuse, mixed with some rough manure, and covered about 8 in. or 10 in. deep with some of the richest and best of the soil that was thrown out of the holes. In the centre are sown four or five seeds 1 in. deep, and these are protected by a flower-pot or an oiled paper cap until they have vegetated. In the fields above alluded to, however, no such trouble is taken; the ground is merely, as previously stated, well stirred and worked, thrown into slight ridges, and the seed sown without any bottom-heat or artificial protection whatever. Thus it will be seen how easy it is to have plenty of Cucumbers, with comparatively little expense in the way of preparation or labour; and that, as a crop, they are remunerative is evident from the fact, that ground which would grow cereals or root-crops in perfection is devoted to Cucumbers even by large cultivators of grain crops. S.

Paraffin Oil and Seeds.—I have not experimented with Peas and paraffin, but I have soaked both Radish and Turnip seeds in it for at least an hour, and afterwards sowed them without their receiving any injury. I tried the paraffin with Radish to see whether or not birds would object to the taste, as both chaffinches and sparrows are ravenously fond of the freshly germinated seeds. They were, however, left alone, but whether the paraffin saved the crop or not, I cannot say. The Turnip seed was soaked in the oil to test its value with reference to keeping off the fly; one-half the seed was steeped and one-half was not, all being sown at the same time side by side. All germinated freely, but as the fly spared all the plants the experiment proves nothing.—A. D.

Transplanting Young Vegetables.—Broccoli, Cabbage, Cauliflower, and all other vegetables of that kind, are generally raised in seed-beds, and many are in the habit of transplanting them into another bed before planting them in their fruiting quarters. We have tried this plan at different times; the plants gain nothing by it, but on the contrary, often lose a great deal. It is well known that no plant can be transplanted without receiving a check, and the less frequently planting is done, the less it will have to overcome. No kind of greens need be planted more than once. When a number of plants come up in the seed-bed, there are always some that take the lead; when the largest have made from four to six leaves, they may be lifted carefully and planted permanently. The smaller ones form a succession to these, and by removing the plants as they grow they never become crowded or drawn up. When these little plants are planted out at first they look as if they would never come to anything, but the roots soon catch hold of the soil, and after that they grow amazingly, and come to maturity sooner and more perfectly than plants which have been half killed two or three times through shifting.—A NORTHERN GARDENER.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Osborn's French Bean.—I find this to be the best Bean for forcing; it is dwarf and compact in habit, and very prolific. *Leveon's Best of All* is also a good forcing variety. I grow my Beans in 8-in. pots, and set them in saucers of manure water, and under this treatment I find them to last in bearing double the time they otherwise would do, and it also saves labour in watering.—J. THOMSON, *Inverloch Castle, Fort William.*

A Little-known Vegetable.—In addition to the vegetable crops commonly grown there are others which would well repay culture in market gardens. One of these is Mercury, or Good King Henry, so largely grown by cottagers in Lincolnshire. This plant, the *Chenopodium Bonus Henricus* of botanists, bears a tender young leaves resembling Spinach, which, when cooked, are but little inferior in flavour to the finest Asparagus. It is a robust-growing perennial, and, when once planted in deep, rich soil, requires no further cultural attention than a dressing of well-decomposed manure during the winter months.—B.

Tying Early Cabbages.—In this neighbourhood tying early Cabbages is an operation largely practised, but not for the purpose of promoting early hearing, as the Cabbages are cut almost as soon as they are tied. I believe it is done more to satisfy a market tradition than anything else, as the cutting of the crop directly after the tying shows that no beneficial result in the growth can follow. Probably Cabbages go to market and are dispersed to the numerous consumers with less injury when tied than would otherwise be the case. Early hearing depends more upon the variety than upon tying; and no amount of tying will make a coarse green into a good compact-hearted Cabbage.—A. D.

THE JUJUBE ZIZYPHUS.

THE Buckthorn family (Rhamnaceæ), includes over 200 widely distributed species, represented in South America by the beautiful genus *Ceanothus*, in Europe and Asia by *Zizyphus*, in South Africa by *Phylica*, and in Australia by *Pomaderris*. The Jujube (*Zizyphus vulgaris* and *Z. Jujuba*) are the species of most interest to the fruit grower. The former is a native of Syria, and is extensively distributed throughout South Europe, North and Western Africa, and Western Asia. This species was introduced into California from France three years ago, and was planted in Sonoma Valley, where the trees have made a vigorous growth, and produced the first crop of fruit last season. It is naturally a prickly, entangled shrub, but may be trained to form a small tree 10 ft. or 12 ft. high. The twigs and small branches are of a reddish-brown colour, and the whole plant is armed with strong, sharp thorns 1 in. in length. The leaves are small and of a delicate green, and the blossoms minute but fragrant. The fruit is of the size and shape of a large Olive, and when

yield its annual crop of valuable fruit. According to Theophrastus, this shrub, or *Z. lotus*, was so common on the island of Lotophagi that a Roman army, on its way to Carthage, subsisted for a time upon its fruit. We would not recommend it to be extensively planted, as the fruit is not likely to prove as acceptable as the more popular varieties now cultivated, but it is well worth a place in every garden for the sake of its delicate foliage and general attractiveness, while its fruit is by no means unpalatable or valueless.

Z. Lotus, another species, native of South and Western Africa, is of less interest for its fruit, though of some importance in its native countries. The berries are of a yellow colour and nutritious. They are converted into a kind of bread, and a beverage is manufactured from them. This fruit is supposed to have formed part of the food of the ancient Lotophagi. This variety has hooked spires, and is a rambling growing shrub. There are other species, including *Z. sinensis*, which produce the fruit sold in the European markets as Japouicas, of more or less importance, which are worthy of a trial in

Fountains in the Gardens at La Granja.

ripe is covered with a smooth, reddish tough skin like that of the Date, which it somewhat resembles in flavour. It has a sweet or sub-acid pulp, surrounding a hard, oblong seed which contains a little oily kernel. The dried or preserved fruit is known in the markets of South Europe as Jujubes, and is much used in France, Spain, and Italy as a sweetmeat on the table, and is said to be an invariable accompaniment in the peasant boy's lunch basket. The well-known Jujube paste of the shops, when genuine, is made of it, though the inventive genius of the age produces a mixture of gum-arabic, sugar, water, and a little colouring matter, without a particle of the fruit, that is disposed of as the "Simon Pure" pâte de Jujubes.

The tree succeeds in almost any soil, if not too wet, and is perfectly hardy in this climate. It is easily raised from cuttings, seeds, or suckers, the latter coming up in abundance around the old trees. Seedlings come into bearing in six or seven years, and suckers and cuttings in two or three. The shrubby habit of the plant and its armament of sharp thorns render it well adapted for the purposes of a hedge plant. Planted thickly it would present an effectual barrier to any animal larger than a squirrel, and would doubtless continue to

California.—"California Horticulturist." [The Jujube of the south of Europe hardly ever reaches the size of a large Olive. Plucked just before it is ripe, crushed and squeezed into water it makes a delicious, slightly acid beverage on a hot day.]

The Fountains of La Granja.—The gardens of La Granja were arranged by Philip V., and intended by him to represent Versailles in miniature. The position he chose was a sterile one, but magnificent on account of the natural advantages it offered. The waters particularly being more limpid than those of Versailles, at that time troubled, contributed in no small degree to make these gardens one of the most beautiful spots in Europe. The Fountain of Latone, of which the accompanying engraving gives an idea, was intended as a special reminiscence of Versailles, without, nevertheless being obliged to see in this monument a copy of the one so generally known and from which it takes its name. The gardens at La Granja show how far-reaching may be the effect of example, bad as well as good.—M. L.

WEeping BROOM.

(GENISTA PROSTRATA).

Few hardy dwarf-growing shrubs rival this in the pure golden colour of its flowers, which are freely produced in spring,

Flower of Weeping Broom (natural size).

and contrast well with the slender, thong-like, almost leafless branchlets on which they are borne. When grown in the

Weeping Broom grafted on the Laburnum.

ordinary way it forms a low, dense-habited tuft, and when planted on natural or artificial rockwork it is an effective plant, quite distinct in habit from the tall *G. scoparius* or Common

Broom of our heaths and commons, of which it is said to be a form. In Messrs. Osborn's nursery, Fulham, this plant and the graceful white-blossomed *Cytisus filipes* are grafted on stocks of the Laburnum, and treated in this manner, both forming pleasing early flowering shrubs for pot-culture in the greenhouse during the spring months. The annexed illustrations show the habit of the plant when grafted standard high, and also its flowers of the natural size. B.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 396).

Lily.

- (1) *Iris*. Thy banks with Peonied and Lilled brims.
Tempest, act iv., sc. 1.
- (2) *Lance*. Look you, she is as white as a Lily and as small as a wand.
Two Gentlemen of Verona, act ii., sc. 3.
- (3) *Julia*. The air has stained the Roses in her cheeks,
And pinched the Lily tincture of her face.
Ibid., act iv., sc. 4.
- (4) *Thisbe*. Most radiant Pyramus, most Lily-white of hue.
Midsummer Night's Dream, act iii., sc. 1.
- Thisbe*. These Lily brows.—*Ibid.*, act v., sc. 1.
- (5) *Perdita*. Lilies of all kinds,
The Flower-de-luce being one.
Winter's Tale, act iv., sc. 3.
- (6) *Princess*. Now, by my maiden honour, yet as pure
As the unsullied Lily.
Love's Labour's Lost, act v., sc. 2.
- (7) *Queen Katharine*. Like the Lily
That once was mistress of the field, and flourished,
I'll lay my head, and perish—*Henry VIII.*, act iii., sc. 1.
- (8) *Cranmer*. Yet a virgin,
A most unspotted Lily shall she pass
To the ground.
Ibid., act v., sc. 4.
- (9) *Troilus*. Give me swift transportance to those fields,
Where I may wallow in the Lily beds
Proposed for the deserter.
Troilus and Cressida, act iii., sc. 2.
- (10) *Marcus*. Oh, had the monster seen those Lily hands
Tremble like Aspen leaves upon the lute.
Titus Andronicus, act i., sc. 5.
- (11) *Titus*. Fresh tears
Stood on her cheeks as doth the honey-dew
Upon a gathered Lily almost withered.
Ibid., act iii., sc. 3.
- (12) *Iachimo*. How bravely thou becomest thy bed, fresh Lily!
Cymbeline, act ii., sc. 2.
- (13) *Guidarius*. Oh, sweetest, fairest Lily!
My brother wears thee not one half so well,
As when thou grewest thyself.—*Ibid.*, act iv., sc. 2.
- (14) *Constance*. Of Nature's gifts thou may'st with Lilies boast,
And with the half-blown Rose.
King John, act iii., sc. 1.
- (15) *Salisbury*. To gild refined gold, to paint the Lily,
To throw a perfume on the Violet,
Is wasteful and ridiculous excess.
Ibid., act iv., sc. 2.
- (16) *Kent*. A Lily-livered, action-taking knave.
King Lear, act ii., sc. 2.
- (17) *Macbeth*. Thou Lily-livered boy.—*Macbeth*, act v., sc. 3.
- (18) For sweetest things turn sourest by their deeds—
Lilies that fester smell far worse than weeds. *Sonnet 91*.
- (19) Nor did I wonder at the Lilies white,
Nor praise the deep vermilion of the Rose. *Sonnet 98*.
- (20) The Lily I condemned for thy hand.—*Sonnet 99*.
- (21) The silent war of Lilies and of Roses
Which Tarquin viewed in her fair face's field.
Rape of Lucrece.
- (22) Her Lily hand her rosey cheek lies under,
Cozening the pillow of a lawful kiss. *Ibid.*
- (23) The colour in thy face
That even for anger makes the Lily pale
And the red Rose blush at her own disgrace. *Ibid.*
- (24) A Lily pale with damask die to grace her.—*Passionate Pilgrim*.
- (25) Full gently now she takes him by the hand,
A Lily prisoned in a jail of snow. *Venus and Adonis*.

Which is the queen of flowers? There are two rival candidates for the honour—the Lily and the Rose; and as we look on the one or the other, our allegiance is divided, and we vote the crown first to one and then to the other. We should have no difficulty “were t’other fair charmer away,” but with two such candidates, both equally worthy of the honour, we vote for a diarchy instead of a monarchy, and crown them both. Yet there are many that would at once choose the Lily for the queen, and that without hesitation, and they would have good authority for their choice. “O Lord, that bearest rule,” says Esdras, “of the whole world, Thou hast chosen Thee of all the flowers thereof one Lily.” Spenser addresses the Lily as

The Lily, lady of the flowering field.

which is the same as Shakespeare’s “mistress of the field” (7), and many a poet since his time has given the same vote in many a pretty verse, which, however, it would take too much space to quote at length; so that I will content myself with these few lines by Alexander Montgomery (coeval with Shakespeare):—

I love the Lily as the first of flowers
Whose stately stalk so straight up is and stay;
To whom th’ have ay lowly louts and cowers
As bound so brave a beauty to obey.

Montgomery here has clearly in his mind’s eye the Lily now so called; but the name was not so restricted in the earlier writers. “Lilium, cujus vox generalit licentiosa usurpatione adscribitur omni flori commendabili”—Laurembergius, 1632. This was certainly the case with the Greek and Roman writers, and it is so in our English Bible in most of the cases where the word is used, but perhaps not universally so. It is also used by Bullein when speaking of the flower of the Honeysuckle (see Honeysuckle), and it must have been used in the same sense by Isaak Walton, when he saw a boy gathering “Lilies and Ladysmocks” in the meadows.

We have still many records of this loose way of speaking of the Lily, as, for instance, in the Water Lily, the Lily of the Valley, the Lent Lily, St. Bruno’s Lily, the Scarborough Lily, the Belladonna Lily, and several others, none of which are true Lilies.

But it is time to come to Shakespeare’s Lilies. In all the twenty-five passages the greater portion simply recall the Lily as the type of elegance and beauty, without any special reference to the flower, and in many the word is only used to express a colour, Lily-white. But in the others he doubtless had some special plant in view, and there are two species which, from contemporary writers, seem to have been most celebrated in his day; the one is the pure White Lily (*Lilium candidum*), a plant of which the native country is not yet quite accurately ascertained, but whether a European plant or not, it probably came to England from the East in very early times. It was certainly largely grown in Europe in the Middle Ages, and was universally acknowledged by artists, sculptors, and architects, as the emblem of female elegance and purity, and none of us would dispute its claim to such a position. There is no other Lily which can surpass it, when well grown, in stateliness and elegance, with flowers of the purest white and the most graceful shape, and sweet scented, and crowning the top of the long, leafy stem with such a coronal as no other plant can show. On the rare beauties and excellences of the White Lily it would be easy to fill a volume merely with extracts from old writers, and such a volume would be far from uninteresting. Those who wish for some such account may refer to the “Monographie Historique et Littéraire des Lis,” par Fr. de Camart d’Hamale, 1870. There they will find more than fifty pages of the botany, literary history, poetry, and medical uses of the plant, together with its application to religious emblems, numismatics, heraldry, painting, &c. Two short extracts will suffice here:—“Le lis blanc, surnommé la fleur des fleurs, les délices de Venus, la Rose de Junon, qu’Anquillara désigna sous le nom d’Ambrosia, probablement à cause de son parfum suivant, et peut-être aussi de sa soûdisante divine origine, se place tout naturellement à la tête de ce groupe splendide.” “C’est le Lis classique par excellence, et en même temps le plus beau du genre.” The other is the large Scarlet or Chaldeonian Lily; and this also is one of the very handsomest, though its beauty is of a very different kind

to the White Lily. The habit of the plant is equally stately, and is indeed very grand, but the colours are of the brightest and clearest red. These two plants were abundantly grown in Shakespeare’s time, but besides these there do not seem to have been more than about half-a-dozen specimens in cultivation. There are now forty-six recognised species, besides varieties in great number.

The Lily has a very wide geographical range, spreading from Central Europe to the Philippines, and species are found in all quarters of the globe, though the chief homes of the family seem to be in California and Japan. Yet we have no wild Lily in England. Both the Martagon and the Pyrenean Lily have been found, but there is no doubt they are garden escapes.

As a garden plant it may safely be said that no garden can make any pretence to the name that cannot show a good display of Lilies, many or few. Yet the Lily is a most capricious plant; while in one garden almost any sort will grow luxuriantly, in a neighbouring garden it is found difficult to grow any in a satisfactory manner. Within the last few years their culture has been much studied, and by the practical knowledge of such great growers of the family as G. F. Wilson, H. J. Elwes, and other kindred liliophilists, we shall probably in a few years have many difficulties cleared up both in the botanical history and the cultivation of this lovely tribe.

But we cannot dismiss the Lily without a few words of notice of its sacred character. It is the flower specially dedicated to the Virgin Mary, and which is so familiar to us in the old paintings of the Annunciation. But it has, of course, a still higher character as a sacred plant from the high honour placed on it by our Lord in the Sermon on the Mount. After all that has been written on “the Lilies of the field,” critics have not yet decided whether any, and, if so, what particular plant was meant. Each Eastern traveller seems to have selected the flower that he most admired in Palestine, and then to pronounce that that must be the Lily referred to. Thus, at various times it has been decided to be the Rose, the Crown Imperial, the White Lily, the Chaldeonian Lily, the Oleander, the Wild Artichoke, the Tulip, and many others, but the most generally received opinion now is, that if a true Lily at all, the evidence runs most strongly in favour of the *L. chaldeonicum*, but that Dean Stanley’s view is more probably the correct one, that the term “Lily” is generic, alluding to the many beautiful flowers, both of the Lily family and others, which abound in Palestine. The question, though deeply interesting, is not one for which we need to be over-curious as to the true answer. All of us, and gardeners especially, may be thankful for the words which have thrown a never-dying charm over our favourites, and have effectually stopped any foolish objections that may be brought against the deepest study of flowers, as that the subject is a petty one, with no great results. To any such silly objections (and we often hear them) the answer is a very short and simple one—that we have been bidden by the very highest authority to “consider the Lilies.”

Lime.

- (1) *Ariel*. All prisoners
In the Lime-grove which weather-fends your cell.
Tempest, act v., sc. 1.
- (2) *Prospero*. Come, hang them on this Lime.
Ibid., act iv., sc. 1.

It is only in comparatively modern times that the old name of Lime or Linden has given place to Lime. The tree is a doubtful native, that has been long introduced, perhaps by the Romans. It is a very handsome tree when allowed room, but it bears clipping well, and so is very often seen tortured into the most unnatural shapes. It was a very favourite tree with our forefathers to plant in avenues, not only for its rapid growth, but also for the delicious scent of its flowers; but the large secretions of honey-dew which load the leaves, and the fact that it comes late into leaf, and sheds its leaves very early, have rather thrown it out of favour of late years. As a useful tree it does not rank very high, except for wood-carvers, who highly prize its light, easily cut wood, that keeps its shape, and is very little liable to crack or split either in the working or afterwards. Nearly all Grindling Gibbons’ delicate carving is in Lime wood. To gardeners the Lime is further useful as

furnishing the material for bast mats, which are made from its bark, and interesting as being the origin of the name of Linnaeus.

Ling.

Gonzalo. Now would I give a thousand furlongs of sea for an acre of barren ground, Ling, Heath, brown Furze, anything.

Tempest, act i., sc. 1.

If this be the correct reading (and not Long Heath) the reference is to the Heather or Common Ling (*Calluna vulgaris*). This is the plant that is generally called Ling in the south of England, but in the north of England the name is given to the Cotton Grass (*Eriophorum*). It is very probable, however, that no particular plant is intended, but that it means any rough, wild vegetation, especially of open moors and Heaths.

Locusts.

Iago. That feed that to him now is as luscious as Locusts, shall be to him shortly as bitter as Coloquintida.

Othello, act i., sc. 3.

The Locust is the fruit of the Carob tree (*Ceratonia siliqua*), a tree that grows naturally in many parts of the south of Europe, the Levant, and Syria, and is largely cultivated for its fruit. These are like Beans, full of sweet pulp, and are given in Spain and other southern countries to horses, pigs, and cattle, and they are occasionally imported into England for the same purpose. The Carob was cultivated in England before Shakespeare's time. "They grow not in this country," says Lyte, "yet, for all that, they be sometimes in the gardens of some diligent Herboristes, but they be so small shrubbes that they can neither bring forth flowers nor fruites." It was also grown by Gerarde, and Shakespeare may have seen it; it is now very seldom seen in any collection, but the name is preserved among us, as the jeweller's carat weight is said to have derived its name from the Carob Beans, which were used for weighing small objects.

The origin of the tree being called Locust is a little curious. Readers of the New Testament, ignorant of Eastern customs, could not understand that St. John could feed on the insect locust, which, however, is now known to be a common and acceptable article of food, so they looked about for some solution of their difficulty, and decided that the Locusts were the tender shoots of the Carob tree, and that the wild honey was the luscious juice of the Carob fruit. Having got so far it was easy to go farther, and so the Carob soon got the names of St. John's Bread and St. John's Beans, and the monks of the desert showed the very trees by which St. John's life was supported. But though the Carob tree would not produce the locusts on which St. John fed, there is little or no doubt that "the husks which the swine did eat," and which the Prodigal Son longed for, were the produce of the Carob tree.

Long Purples.

Queen. Therewith fantastic garlands did she make
Of Crowflowers, Daisies, Nettles, and Long Purples,
That liberal shepherds give a grosser name,
But our cold maids do Dead Men's Fingers call them.

Hamlet, act iv., sc. 7.

In "Flowers from Stratford-on-Avon" (a pretty book published a few years ago with plates of twelve of Shakespeare's flowers) it is said that "there can be no doubt that the Wild Arum is the plant alluded to by Shakespeare as forming part of the nosegay of the crazed Ophelia;" but the authoress gives no authority for this statement, and I believe that there can be no reasonable doubt that the Long Purples and Dead Men's Fingers are the common purple Orchises of the woods and Meadows (*Orchis Morio*, *O. mascula*, and *O. maculata*). The name of Dead Men's Fingers was given to them from the pale palmate roots of some of the species (*O. latifolia*, *O. maculata*, and *Gymadenia conopsea*), and this seems to have been its more common name.

Then round the meddowes did she walke,
Catching each flower by the stalke,
Such as within the meddowes grew,
As Dead Man's Thumb and Harebell blew;
And as she pluckt them, still cried she,
Alas! there's none 'ere loved like me.

—*Roxburghe Ballads.*

As to the other names to which the Queen alludes, we need not inquire too curiously: they are given in all their liberality and grossness in the old "Herbals," but as common names they are, fortunately, extinct. Nor are the names of Long Purples and Dead Men's Fingers still in use, as far as I am aware, for I can only find one example—

Round thee blow, self-pleached deep,
Bramble Roses faint and pale,
And Long Purples of the dale.

"A Dirge."—*Tennyson.*

and the Orchis, though so common, is without an English name, for though I have often asked country people for its name, I have never obtained one, and so it is another of those curious instances which are so hard to explain, where an old and common English word has been replaced by a Greek or Latin word, which must be entirely without meaning to nine-tenths of those who use it.* There are similar instances in Crocus, Cyclamen, Hyacinth, Narcissus, Anemone, Beet, Lichen, Polyanthus, Polyphy, Asparagus, and others.

The Orchid family is certainly the most curious in the vegetable kingdom, as it is almost the most extensive, except the Grasses. Growing all over the world, in any climate, and in all kinds of situations, it numbers 3000 species, of which we have thirty-seven species in England; and with their curious irregular flowers, often of very beautiful colours, and of wonderful quaintness and variety of shape, they are everywhere so distinct that the merest tyro in botany can separate them from any other flower, and the deepest student can find endless puzzles in them, and increasing interest.

Though the most beautiful are exotics, and are the chief ornaments of our stoves and hothouses, yet our native species are full of interest and beauty. Of their botanical interest we have a most convincing proof in Darwin's "Fertilization of Orchids," a book that is almost entirely confined to the British Orchids, and which, in its wonderfully clear statements, and its laborious collection of many little facts all leading up to his scientific conclusions, is certainly not the least to be admired among his other learned and careful books. And as to their horticultural interest, it is most surprising that so few gardeners make the use of them that they might. They were not so despised in Shakespeare's time, for Gerarde grew a large number in his garden. It is true that some of them are very impatient of garden cultivation, especially those of the *Ophrys* section (such as the Bee, Fly, and Spider Orchises), and the rare *O. hircina*, which will seldom remain in the garden above two or three years, except under very careful and peculiar cultivation. But, on the other hand, there are many that rejoice in being transferred to a garden, especially *O. maculata*, *O. mascula*, *O. pyramidalis*, and the Butterfly Orchis of both kinds (*Habenaria bifolia* and *chlorantha*). These, if left undisturbed, increase in size and beauty every year, their flowers become larger, and their leaves (in *O. maculata* and *O. mascula*) become most beautifully spotted. They may be placed anywhere, but their best place seems to be among low shrubs, or on the rockwork. Nor must the hardy Orchid grower omit the beautiful American species, especially the *Cypripedia* (*C. spectabile*, *C. pubescens*, *C. acaule*, and others). They are among the most beautiful of low hardy plants, and they succeed perfectly in any peat border that is not too much exposed to the sun. The only caution required is to leave them undisturbed; they resent removal and broken roots; and though I hold it to be one of the first rules of good gardening to give away to others as much as possible, yet I would caution any one against dividing his good clumps of *Cypripedia*. The probability is, that both giver and receiver will lose the plants. If, however, a plant must be divided, the whole plant should be carefully lifted, and most gently pulled to pieces with the help of water.

Love-in-Idleness.—(see Pansy).

Mace (see Nutmeg).

H. N. ELLACOMBE.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

VEGETATION in all its forms this spring is more backward than in previous years when the winters have been more severe, and even now near the end of May outdoor flowers are comparatively scarce, especially on badly-drained, stiff soils. In many of the small gardens near London may, nevertheless, be seen in good bloom such plants as *Scilla nutans* and *S. campanulata*, various kinds of *Iris*, *Daisies*, and other easily-grown plants. Amongst *Tulips* *T. præcox*, *persica*, and *fulgens* are attractive, as are also the scarlet-tipped, yellow-petalled flowers of *T. cornuta*, and the pale yellow blossoms of *T. retroflexa*. *Iris susiana* is now throwing up fine spikes of flower; some plants of it that have had the protection of a cold house have produced immense blooms; the beautiful blue-flowered

Presli's Catchfly (*Lychnis Preslii*).Annual Lupine (*Lupinus bicolor elegans*).

Gentiana verna is just now in great beauty, and the dwarf *Phloxes*, *P. subulata*, *P. setacea* *atro-purpurea*, and the white-flowered *P. Nelsoni*, are completely covered with bloom; the purplish flowers of *Lychnis Preslii*, too, are opening in abundance, and the Alpine *Lychnis* (*A. alpina*) is densely covered with rosy-pink blossoms. American *Cowslips* are likewise in a forward state, especially *Dodecatheon Jeffrayanum*. On the Scarlet *Geum* (*G. coccineum*) quantities of blossoms may now be seen, and *Saxifraga peltata* is also flowering freely. Amongst the *Globe-flowers*, too, which are just now at their best, may be noticed the rich golden-flowered, dwarf-habited *Trollius Fortunei*. Several varieties of the *Rock*

Early Dwarf Pentstemon (*P. confertus*).*Limnanthes Douglasi*.

Cistus are also flowering freely. Blooms of *Narcissus juncifolius* may still be gathered in good condition, as may also those of the White Wood Lily (*Trillium grandiflorum*). *Ranunculus amplexicaulis* is still in good bloom, and the small, double, pure white blossoms of *R. aconitifolius* are likewise abundant and highly valued by those who have small bouquets to make. Some of the hardy *Lady's-slippers* are well furnished with bloom-buds, while those of *Cypripedium pubescens* are already open. *Polemonium reptans* is flowering freely, as are also the yellow *Lasthenias* and the blue and white *Nemophilas*. *Uvularia grandiflora* is graced with drooping yellow blossoms, and several kinds of *Fritillaria* and the White Thrift (*Armeria cephalotes alba*) are likewise in flower. *Primula*

erosa, too, is still attractive, as are also *Ornithogalum umbellatum* and *O. balticum*, both of which are bearing large clusters of white flowers. At Kew, the tall flower-spikes of *Camassia Leichtliui* are very attractive, being thickly beset with large, creamy-yellow blossoms. *Pæonias* are now very attractive, especially *P. anomala* and *P. tenuiflora* and its varieties. *Aquilegias*, too, are flowering freely at Kew, as is also the dwarf, sulphur-coloured *Platystemon californicus*. Large beds of a dwarf yellow Wallflower, named Ware's Tom Thumb, are very showy. For border edgings, for banks, or for pot culture, this Wallflower is worth growing, on account of its remarkably dwarf habit and floriferous character. S.

DEATH OF JAMES BARNES.

ALL acquainted with the best of what we are now beginning to call the old school of British gardeners, will hear with regret of the death of James Barnes, which took place on the 23rd inst. at Exmouth, at the age of 71. He has lived there in retirement since giving up the charge of the famous gardens at Bicton. Of these he had the management for nearly thirty years, and, as many of our readers know, under his charge they were among the most richly-stored and best-managed gardens in the country, the arboretum being probably the richest, and the kitchen garden one of the best cultivated in England. James Barnes, when young, had much experience in the best London market gardens, and evidence of this was seen in the thoroughness of much of his work. Beginning life with very few educational advantages, he took an intense interest in the literature of his work, and was a constant contributor of readable practical articles to the press, including *THE GARDEN*, to which he gave his hearty support from the commencement. For a man who had no early advantage of travel to free him from prejudices, he to the end showed a singular freedom of mind in his determination to see anybody's practice likely to be suggestive, no matter where or by whom it was done. Thus, only a few years ago he made a long excursion round Paris, and examined the market and fruit gardens there with the greatest zest and interest. He was a close and constant observer of natural history, as shown in the lives of the birds and animals in the gardens and woods under his care, and contributed many instructive and interesting notes on those subjects to the "Field" and various other journals. It was interesting to those who had the pleasure of walking round the arboretum with him to notice that not a small bird showed itself on the boughs of the highest trees that he did not seem to instantly take notice of. So it was in the case of every other creature about the gardens or woods. Probably few of our readers will require to be told that he was the brother of William Barnes, who for many a day was considered the best plant grower about London. Like his brother, he was in early life blessed with a fine physique, and the story of his intelligence and energy was written in a fine face, like that of the stoutest type of Saxon, but lit up with a clear eye and the brightest intelligence. His success as a gardener, charm of manner, and pleasant writing are easily traceable to an inexhaustible stock of what, by an odd perversion of language, we are obliged to call common sense. The sad fact is that both the type of man (whose loss we now regret) and the sense are rare. James Barnes had gifts which, cultivated and exercised in other ways, would probably have made him famous far beyond what is possible in the walk to which his life was so conscientiously devoted. W. R.

Lime Juice and the Arctic Failure.—The failure of the Arctic Expedition is not due to any ignorance on the part of medical authorities of the main conditions essential to success, but to the deliberate disregard of such conditions by the commander of the expedition. The committee attribute the early outbreak of scurvy in the spring sledging parties of the expedition to the absence of lime juice from the diet of the men. The committee find that the provision made by the Admiralty in the way of food, medicines, and medical comforts was in every respect adequate for the performance of the special service in which the expedition was engaged, and was more complete than had been made for any previous Arctic Expedition. The means, in short, were all at hand for obviating the disease which is the great enemy of all such enterprises; but, by a lamentable failure of judgment, they were not used. Sir George Nares took upon himself to neglect the positive advice of the highest medical authorities of the Navy, even when it had been officially recommended to his attention; and his reputation and the health of his crews paid the penalty.—"Times," May 19.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Flower Garden.—The general stock of bedding plants, with the exception of a few of the most tender kinds, should now be planted out without delay. There is at least a difference of ten days between the southern and northern parts of the kingdom when it is advisable to bed out. A few fine days often tempt amateurs to put out tender plants before there is sufficient warmth in the ground, for even should no actual frost occur after they are exposed, if only a few nights come wherein the temperature falls near to the freezing point, it has a stunting effect upon them, from which it will take a fortnight's fine weather to restore them; and if the plants receive plenty of water and be well cared for in other ways, they keep on growing in their pots or boxes up to the time they are turned out. A few words as to the operation of planting may be of use to those who are not experienced in the mode of preparing the soil, &c., for the reception of such subjects as have yet to be planted. Where the soil is of a strong, adhesive nature, this season it requires double the ordinary amount of labour to break it sufficiently fine for the roots to enter freely; and it must be borne in mind that in the class of plants under consideration the ability of the roots to extend is limited, having to draw their sustenance from the soil immediately near them, and if this at the time of planting be left in a rough, lumpy state underneath, even though it is broken quite fine on the surface, the roots cannot penetrate these hard, unbroken clods, through which cause the subsequent progress of the plants will be comparatively slower; consequently, even where the ground has been previously well dug in heavy land it will be necessary to work it over again with the fork, thoroughly breaking all the lumps to as great a depth as the roots of the plants are likely to penetrate. In light soils there will be no occasion for this extra labour, but where the land is at all dry all the holes intended for the reception of the plants should be made considerably larger than is necessary for their roots, and filled up with water twice, so as to give the under surface a thorough moistening; when the water has had time to settle the bed may be planted. This operation takes a little more time in the first instance but saves much labour in subsequent waterings of the surface, while its effects in promoting quick and strong growth are much more effectual, especially if the surface be immediately mulched over with an inch or so of some fine non-moisture-conducting material that will check evaporation, for which purpose there is nothing equal in appearance to Cocoa-nut fibre; where this is not available, a good substitute will be found in well-decomposed leaf-mould or exhausted tan that has become quite black by exposure, and is reduced to almost a fine powder. These two latter, previous to being laid on, should be passed through a half-inch sieve, and the finer portion placed on the beds, to give them a neat appearance. As soon as this is completed, Verbenas, Ageratums, Heliotropes, and Petunias, or any plant of a straggling habit easily affected by the wind should at once be pegged down, or they frequently get broken or injured near the collar by friction with the soil; for this small hooked sticks may be employed, or what will be found equally as serviceable, pieces of hast about 8 in. long looped round the shoots, and the ends thrust down into the soil with a small dibble. Previous to planting out see that everything on which aphides will live is quite free from them, for, if there be only a trace of these insects on the plants, their subsequent destruction will entail a good deal of trouble; it is not well to be content with fumigating and killing the mature insects, as they will leave a quantity of eggs which the smoke will not affect that will produce insects in a few days, but which can be effectually destroyed by dipping each plant in Tobacco or Quassia water.

Kitchen Garden.—Embrace every favourable opportunity when the land is in a half moist condition to stir as deeply as possible betwixt growing crops with hoe or fork, without interfering with the roots; there is a twofold benefit arising from this operation—it checks the growth of weeds better than ordinary shallow hoeing, and to some extent it makes up for the unfavourable condition of the soil when sowing and planting were carried out this season, except in places where the land is of an exceptionally open nature.

Asparagus, Spinach, Beans, &c.—Asparagus has been unusually late this season, consequently cutting may be continued longer than usual; this in all cases should be regulated by the strength of the beds where the plants are young and not yet come into full bearing, and in old beds, where the plants are now, they should not be cut for so long a time as those that are in full vigour; but in most cases I should recommend the whole (large and small) being cut so long as the cutting is continued. Continue to sow Spinach once a fortnight; it is not advisable to put in more at each sowing of

this vegetable than will be required, as if not used immediately it is fit, it runs to seed in a few days during the hot summer weather; to avoid this as much as possible, sow thinly in rich ground. Where Broad Beans are held in particular estimation, another sowing should now be made; these late sowings, however, except in soil especially adapted to their growth, do not succeed so well as the earlier ones. Make another sowing of Dwarf French Beans, and also of Runners; the latter will come in after the first-sown, which in protracted summers sometimes become exhausted before the hard weather cuts them off.

Carrots, Parsnips, Leeks, and Onions.—Carrots and Parsnips should now be thinned, leaving the latter 9 in. or 10 in. apart in the rows; in the case of Carrots it is well to leave them at the first thinning doubly as close as they are ultimately to remain, about 4 in. asunder, every alternate plant afterwards being drawn for use when they have attained the thickness of a person's finger; so managed the general crop is not interfered with, and those that are used half-grown afford an acceptable supply during the early part of the season. A piece of ground in an open situation should now be prepared for Leeks. This vegetable, to be well grown, requires a soil deeply dug, with a quantity of manure worked in down to the bottom of the trench in order to supply its descending roots with abundant food. Where Leeks are grown in badly-cultivated and poor soil they are stringy in texture and hot, more approaching the character of Onions than when well-grown to a large size, which gives them the peculiar flavour so much esteemed by some people. They should be planted with a large dibble, making holes about 9 in. or 10 in. deep, putting the plants into these, and then dropping in an amount of soil just sufficient to cover the roots, but not filling the holes. By planting deeply in this manner it allows room for the stems to expand, and when ready for use they will be blanched up to the required height; give them water to settle the soil about the roots; they will need nothing farther through the season but hoeing betwixt the rows to keep down weeds. Make the rows 1 ft. apart, the plants standing 9 in. asunder in the rows. Thin out the principal crop of Onions, choosing a time when the soil is moist, by which means those that have to be removed will draw freely without disturbing the roots of those that are to remain. It is this season more than usually necessary to attend to this, on account of the plants being so backward that the time there exists for their coming to maturity is very short. Those required for pickling (unless they have come up very thickly) should not be thinned at all; if the plants touch each other it will tend to keep them small, in which way they are the most generally preferred.

Ridge Cucumbers.—Some slightly fermenting materials should be prepared now for Ridge Cucumbers: stable-manure and leaves are the best where available, a substitute for which may be had in Grass mowings from the lawn, weeds, the tops of greens that are running to seed, or garden refuse of any kind, mixed with some of last autumn's leaves if at hand. Choose a dry, open place in the garden exposed to the sun, open a trench 4 ft. wide and 10 in. deep; into this put the material, making it about 2½ ft. deep, rounding it off in a ridge at the top, on this place the soil that has been taken out mixing some rotten manure or leaf-mould with it, then turn out the plants, two or three together on the top in patches 6 ft. apart, covering each group with a hand-light, which must be tilted so as to give air in the daytime, and closed down at nights for a few weeks until the plants have got fairly into growth. Plant in two or three days after the material is put together, by which time the ridge will be slightly warm, there not being sufficient body to endanger its becoming too hot.

Celery and Small Salads.—Some of the earliest kinds of Celery may now be planted. When the trenches have been recently prepared and a considerable body of manure dug in, where the soil is at all of a light nature, the plants will succeed better if, previous to being put in, the trenches be made more solid by a slight treading down. Of all calinary vegetables Celery is the most moisture-loving, and unless the ground is more than usually moistened by rain, I have found it of the greatest assistance to the plants to give the trenches a thorough soaking before planting—not a simple watering, such as is generally applied to other crops, but a complete saturation of the soil. Where this is done the plants grow vigorously, and will keep on for many weeks (no matter how dry the weather is) without further attention. If grown in double rows insert the plants 1 ft. apart each way, if in single rows, 9 in. will be enough; previous to moving them from the nursery bed water sufficiently to moisten the whole of the soil about the roots; by this means they can be moved with little loss of root and attached soil. Small Salads and Radishes, where in continuous demand throughout the season, should be sown every fortnight.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

May 28.—Shifting some variegated Pelargoniums and Petunias, both double and single varieties, for the autumn decoration of the conservatory. Sowing Green Curled Endive between rows of Peas; also Curled Parsley, Rampion, and Cauliflower. Planting Stocks, Asters, Malope, and spring-sown Cauliflower plants into manured trenches; also Vegetable Marrows and Ridge Cucumbers, affording them the protection of handlights or mats by night, and slightly shading them from the sun by day. Refilling vases on terrace with summer-flowering plants. Cleaning herbaceous borders. Taking down coverings from fruit trees, and storing them away. Tying and staking Dahlias recently planted, to prevent them being blown about by the wind. Thinning spring-sown Onions, afterwards hoeing the ground between the rows.

May 29.—Potting Poinsettias, Pinks, scented-leaved Pelargoniums, and Heliotropes. Sowing American Red-top Turnips, Maize, Melons, and Victoria, Drumhead and Paris Green and White Cos Lettuces. Planting out Tomatoes in warm situations; also Early Cabbage, Lettuce, and Cauliflower plants that were raised from seed sown in the open air. Putting in Fuchsia cuttings, to furnish a batch of young flowering plants in autumn. Pricking out Celery plants in very rich soil, and keeping them well supplied with water. Removing Raspberries that have been grown in pots indoors to a sheltered border. Earthing-up Jerusalem Artichokes. Thinning Carrots and Parsnips. Washing Gooseberry trees with alum water to kill caterpillars, and syringing Peach and Nectarine trees with soft soap and Tobacco-water, to clear them of aphides. Placing Cinerarias that have ceased flowering, and from which cuttings are required into cold pits. Putting soil in Melon pits ready for planting.

May 30.—Potting Chrysanthemums intended for standards into 8-in. pots; also re-potting Heliotropes and Verbenas, and placing them in greenhouse. Sowing another crop of Scarlet Runners, Veitch's Perfection and No Plus Ultra Peas; also Parsley in well-watered drills, and Endive of sorts. Planting Stocks, Asters, and Lobelias on Vine borders, and Lettuces among Seakale plants. Pricking out Celery on rotten manure slightly covered with soil. Preparing Broccoli land for late Peas. Raking and otherwise cleaning rough shrubby borders. Cutting out dead Laurels, and removing overhanging boughs of trees and shrubs in pleasure grounds. Plunging outdoor pot Roses in a sunny situation. Thinning Plums, and nailing in leading growths of Peaches, Nectarines, and Apricot trees. Washing Odontoglossums and Saccolabiums; hoeing among kitchen garden crops, and weeding walks in pleasure grounds.

May 31.—Potting Zinnias, Delphiniums, and Lemon-scented Verbenas, and placing them out-of-doors. Potting-off seedling Cinerarias, herbaceous Calceolarias, Amarantus, and Solanums. Sowing Mignonette in 6-in. pots for indoor decoration; Red Globe Turnip, Cabbage seed for Coleworts, and a few pots of Legg's Melon. Planting Vegetable Marrows and Ridge Cucumbers on prepared ridges, and refilling conservatory baskets for the summer. Pricking-off Carnation cuttings and young Celery plants. Training Creepers on house-sides and on verandah. Thinning Malope. Dribbling in and watering Spinach seed where blanks have been caused in the rows. Re-arranging Odontoglossum-house. Watering Celery, Violets, Radishes, Turnips, and all seed-beds; also Dahlias that are planted out. Top-dressing Lillium auratum with sandy peat, and preparing more places for Vegetable Marrows.

June 1.—Potting off Celosias, Love-lies-bleeding, and Tree Carnation cuttings that are sufficiently rooted. Blocking Dendrobium Falconeri, and basketing D. Pierardi, Devonianum, and chrysanthum. Sowing Radishes and Mustard and Cress on well-watered beds; also Chicory, Syon House French Beans, Spinach, and another lot of Cucumbers. Planting Ferns of different kinds under Orchid-house stages, and pricking out young Chinese Primulas and main crop of Celery plants. Pulling up Wallflowers that have ceased blooming, and manuring and digging the land thus cleared for Stocks. Clearing up surplus bedding plants. Hoeing among Strawberry plants and afterwards mulching them with short Grass. Placing Primulas in cold frames, and shading them from the direct rays of the sun. Nailing the leading shoots of wall fruit trees.

June 2.—Potting Tropæolum canariense into 6-in. pots for the decoration of wire stands, baskets, verandahs, &c. Re-potting Dendrobium fimbriatum oculatum and Perestera elata, using for the latter a compost of loam, peat, sand, and manure. Shifting Balsams and Cockscombs into flowering pots. Planting Tomatoes under wall in sunny situations. Thinning spring-sown Onions. Watering Cauli-

flowers with manure-water; also outside Peach and Vine borders. Syringing Cherry trees and Roses infested with aphides with a solution of soft soap and Tobacco-water. Digging land for Myosotis, Wallflowers, and Daisies, and manuring and digging border for Cauliflowers. Hoeing among Cabbage and Onion plantations.

Hardy Flowers.

ANTIRRHINUMS.—The experience of the past winter has shown that old plants of Antirrhinums, left to flower the second year, have died through excess of moisture. It is wet rather than frost that kills many hardy plants. On the other hand, plants raised from seed sown in August last have stood unharmed, and will soon be showing bloom. If seed be sown in March and April, the plants will bloom in September and October. Seedling plants of the first year are always dwarfer in growth than plants kept over to the second year, and that is an additional reason for raising seedlings.

CARNATIONS AND PICOTEES.—Plants that are in large pots for blooming will need to have the growing stems tied to sticks. With few exceptions all shoots starting bloom besides the leading stems should be stopped, if blooms be wanted for show purposes in July. Green fly and spittle fly, as it is termed, are apt to become troublesome, and should be removed. During warm weather a free use of the syringe greatly conduces to the cleanliness, and consequently to the health and vigour of the plants. Plants in borders that are required only for flowers may be allowed to carry several flower-stems according to their strength. A top-dressing of good, rich soil is of great service during the summer.

CHEIRANTHUS.—The fine dwarf perennial forms of the Cheiranthus or Wallflower are now getting into fine bloom. *C. alpinus* has pure pale yellow flowers; *C. Marshalli*, which is said to owe its colour to a cross between *C. alpinus* and the annual *Erysimum Peroffskianum*, is of a pleasing orange hue; then there is the curious yellow and brown *C. Dillenii*. They are of dwarf growth, forming good tufts for rockwork and borders, and bloom with great freedom. Some attempts have been made to cross these with the common Wallflowers, and interesting results are obtained, but nothing as yet of an enduring character.

MARIGOLDS.—These should now be planted out in rich ground. In the mixed border they look best planted singly, and thus treated they make good bushy specimens. A little manure water given during the summer greatly assists the production of fine flowers. The double pot Marigold, or, as it is sometimes termed, the *Ranunculus Marigold*, is a showy plant, the large golden flowers of which are very attractive.

MIMULUSES.—Improved strains of these have very large and finely marked flowers, and in most cases these are associated with a bold vigorous habit. A cool-house is the best place for plants in pots, and if well looked after, watered, and occasionally syringed, they will keep effective for a considerable length of time. A pan of seedlings will give a succession of plants that will last all through the summer.

MYOSOTIS.—The frosts of the first week in May sadly cut back *M. dissitiflora*, but in a few days, assisted by rain and invigorated by sunshine, it was quickly in blossom again, and is now as gay as ever. It is a wonderfully free bloomer, and during the flowering season the plants throw out a number of lateral shoots which produce flowers. The blue, white, and rose coloured varieties of *M. sylvatica* are now getting gay, but they are considerably later than *M. dissitiflora*. The pretty *M. azorica* and the fine varieties raised from it used to be much more grown in pots for summer decoration than they are now, and very charming they were when well grown. A little trouble is, however, required to get the plants in good condition, and, indeed, they should have the treatment of a warm greenhouse till hardened off to bloom in a cool house. The charming little *M. rupicola* is beginning to show its lovely blue flowers from amid little tufts of foliage in pots.

PETUNIAS.—The plants intended to flower in the open ground should be got out into beds and borders at once, as the showery weather will give them a good start. As an invariable rule plants should be put out in the open ground with good balls of earth about their roots; and should it become shaken off in course of transplantation, some fine soil should be substituted in order to afford something to root into at once. Plants put out with but little roots and congenial soil about them, are very slow in starting into growth. The way to secure an effective bed of Petunias is by pegging the main shoots to the ground, and leaving the side shoots to produce a good surface of foliage, which should be pinched out occasionally to form an even mass. In this way a grand display can be had all the summer. Petunias are well suited for stone vases, beds, and baskets; as they hang down over the sides, and form an attractive floral

fringe. They are also useful decorative plants in pots; and when they are well grown they can scarcely be excelled among soft-wooded plants. The chief point is to get a good-shaped plant by keeping it pinched back until the desired form is secured, then it may be permitted to flower. The double varieties are, with but few exceptions, better fitted for pots than for the open ground.

SAXIFRAGA GRANULATA FL. PL.—This is a most useful hardy plant at this season of the year. Its growth is dense and tuft-like, and it flowers freely. A fairly light sandy soil suits it best. What a charming combination might be made of *Anemone fulgens*, *Myosotis*, and this Saxifrage, with an appropriate edging! One plant of this Saxifrage can be quickly increased to many, and it is useful in a cut state, as the flowers last a long time in water. D.

Forest Trees.

This season's bark stripping commenced here on April 27, being one day earlier than last year, which latter was a week or ten days later than the average time for commencing. The operation this season, too, was somewhat similar to that of last year, as regards the unfavourableness of the weather during the first two weeks. Keen frosty nights and north-east winds continued intermittingly from the commencement to the 9th inst; after that date, however, there was a change for the better—southerly winds and growing showers daily had a beneficial effect on the work, causing the sap to flow more freely and rendering the bark easier to peel off, thus somewhat compensating for the harsh weather at the commencement, and prolonging the season a few days. Bark stripping generally was finished in this neighbourhood on the 17th inst. From reliable information I am informed that Oak bark has advanced from 15s. to 25s. a ton throughout the country on last year's prices, in consequence it is said of Valonia having nearly doubled in price through the blockade of the Turkish ports, from which and other parts of the East this tanning material is imported—hence the reason of the rise in Oak bark. We sold our bark at an advance of 17s. 6d. per ton, the price being £5 for 21 cwt. put on the wagon in the wood; the price paid to the woodmen for taking off the bark, drying, and loading it on the purchaser's wagons, is 2s. per ton of 20 cwt. I hear that the annual sale of Oak bark in the New Forest realized about 21s. a ton more than last year, the sale averaging £6 12s. in the wood. In Shropshire in one locality the price has been, I am informed, 25s., and in Staffordshire bark has realized from £6 to £6 10s. per ton of 20 cwt. in the wood. The timber trade (home-grown) remains quiet, having been dull for the last eighteen months or more. Trees of large dimensions and of first quality only in demand at high prices.—*GEORGE BERRY, Longleat.*

SOCIETIES AND EXHIBITIONS.

MANCHESTER GREAT FLOWER AND FRUIT SHOW.

THIS great Whitsuntide display of flowers and fruits was acknowledged to be the best ever held in Manchester. Orchids, Roses, and stove and greenhouse plants were shown in profusion and in unusually good condition both by amateurs and nurserymen. In the amateurs' class of twenty stove and greenhouse plants, ten fine-foliaged and ten in flower, Mr. Edward Pilgrim, Cheltenham, was first. His best plants were *Tetratheca ericifolia*, *Croton Weismanni*, a marvellous *Cycas circinalis*, the grand, double, white *Azalea*, called *Flag of Truce*, and an *Erica* named *Victoria*, an English hybrid, and the finest plant of its kind ever exhibited. It was raised by the late Mr. Story, of Exeter, to whom we are indebted for so many charming hybrids. The second prize was won by Mr. Shuttleworth, Preston, who had *Croton undulatum*, a grand *Dendrobium nobile*, bearing no fewer than 500 flowers; a *Flamingo*-plant, with fifty or sixty flowers, and two or three magnificent *Gleichenias*. The third prize was awarded to Mr. John Rylands, Stretford, for, among others, *Erica Cavendishiana*, a grand *Alcassia Lowi*, and a beautiful *Areca rubra*. Of greenhouse *Azaleas*, there was only one collection, and that came from Mr. Broadhurst. In the class of twelve stove and greenhouse plants, six foliage and six in flower, the first prize was awarded to Mr. H. Samson, Bowdon, who showed a beautiful *Cocos Weddelliana*, the finest, perhaps, in the show; a remarkably good *Hedera macrotipifera*; a noble *Latania borbonica*; *Croton angu-titulum*, much better than usual, and a couple of *Gleichenias*. Mr. Shuttleworth, who was second, had a superb *Croton majesticum*; a very good *Erica ventricosa minor*; two finely grown *Gleichenias*; and a remarkably fine specimen of the *Flamingo*-flower, the serpent-like spades of which tell effectively against the gorgeous scarlet spathes. The only Heaths shown came from Mr. Pilgrim. Manchester has now for more than forty years been famed for its Orchids, a circumstance no doubt in part attributable to the wealth created in this busy haunt of commerce, but bearing testimony also to the good taste of those who grow them. The premier prize on this occasion for Orchids was awarded to Mr. O. O. Wrigley, Bury. It contained *Thunia Bensoniæ*, with twenty-five or thirty flowers; *Thunia Marshallii*; *Vanda suavis*, with seven great odoriferous racemes; an *Odontoglossum crispum*, with twelve clusters of white, lilac, and golden flowers; a marvellous group of

Masdevallia Harryana, *Cypripedium niveum*, and *Ada aurantiaca*; *Calanthe veratrifolia*, one of the most beautiful plants in the show; *Saccolabium guttatum giganteum*, with five grand rosy-lilac flower-spikes 20 in. long; *Anguloa eburnea*, quite a show of quaint ivory shell-like blossoms. Dr. Ainsworth, who was second, had *Phalenopsis grandiflora* finely in flower, the beautiful *Dendrobium crassinode*, a splendid *Saccolabium guttatum*, with nearly a dozen perfect racemes; *Odontoglossum Pescatorei*, one of the loveliest of its genus; an exceedingly good *Cattleya Mendeli*; *Vanda Denisoni*, bearing a couple of greenish-white racemes; and though last, not least, *Dendrobium Ainsworthi* and its rose-coloured variety. These two charming plants are hybrids, or crosses between *D. nobile* and *heterocarpum*. The third prize was awarded to Mr. Aders, Whalley Range, who showed some extremely beautiful plants, and among them a *Dendrobium Schröderi*, which looked like a white variety of *D. densiflorum*; an *Odontoglossum triumphans*, with twenty-five flowers, yellow blotched with bright cinnamon; the hybrid *Cypripedium Dominianum*, with fourteen flowers, and probably the finest plant of its sort in the country. Mr. Aders showed *Dendrobium Dalhousieanum*, and others. In the class of eight Orchids Mr. Wrigley was again first. His best plants were *Lycaste Skimeri*, *Dendrobium crepidatum*, *D. lituiflorum*, and a charming *Odontoglossum vexillarium*, seemingly ornamented with twenty-five pink butterflies, each about 2 in. in length. Mr. Joseph Broome, who was second, had a fine *Vanda tricolor*, *Masdevallia Veitchi*, a delightful *Lælia purpurata*, and *Aerides Fieldingi*, one of the most valuable of Orchids. Dr. Ainsworth, who was third, showed a noble *Vanda suavis*, with nine or ten racemes in perfection, the somewhat rare *Dendrobium Wardianum*, and some exceedingly good *Odontoglossums*. In the class of three Orchids, Mr. Wrigley was awarded the first prize for an admirable *Calanthe veratrifolia*, an *Anguloa Clowesi* with some thirty or forty yellow Tulip-like flowers, and a beautiful example of *Masdevallia Harryana*. Mr. James Fildes was second with *Dendrobium densiflorum*, bearing sixteen or eighteen rich, orange-coloured racemes falling away, as it were, from a mound of lively green. Mr. J. Taylor, Newton Heath, had a good *Dendrobium nobile*. Fine-foliaged plants and Ferns were well represented. For *Adiantums*, Mrs. Leech, of Stalybridge, carried off the first prize, and Mr. Shuttleworth, of Preston, the second. Filmy Ferns, which came from Mr. Ryland, Mrs. Leech, and Messrs. Standish & Co., consisted of *Hymenophyllum flexuosum*, *crispatum*, and *demissum*, *Trichomanes radicans*, and *Todea superba*. Messrs. James Dickson & Sons, of Chester, obtained the first prize for a pair of Tree Ferns with *Dicksonia antarctica*. Miss Pearson had a beautiful plant of *Osmunda cinnamomea*, and we also observed some specimens of the different varieties of the Lady Fern. Roses in pots were shown by Mr. Turner, Slough, and Messrs. Paul & Sons—Mr. Turner being first. Amongst his plants Paul Perras, Madame de St. Joseph, La France, Charles Lawson, and Miss Ingram, were in unusually good condition. From Messrs. Paul came very fine plants of *Souvenir d'un Ami*, Madame Margottin, Camille Bernardin, Madame Thérèse Levet, Victor Verdier, and others. The thirty Roses in 9-in. pots also formed an interesting exhibition, all the finest and newest sorts being represented. Of new plants few were exhibited which have not been already described. Among exhibitors of miscellaneous plants were Messrs. James Dickson & Sons, Chester, and Mr. Smith, Worcester, and we also noticed a group of *Amaryllises* from Mr. James Anderson, of Meadowbank. *Pelargoniums* and *Lilies* were shown by several exhibitors, and there was a good though small exhibition of fruit. A list of the prizes awarded in the different classes will be found in our advertising columns.

NOTES AND QUESTIONS—VARIOUS.

Lentils.—Will any reader of *THE GARDEN* kindly answer for me the following questions? (1) What are the present prices of Lentils per bushel, and per lb.? (2) Is there any way of restoring Lentils that have become damp and sour to their proper state? (3) In what way may they be prepared and cooked for human food.—A. X. A.

The Snake's-head Fritillary in Middlesex.—I have sent you flowers of *Fritillaria Meleagris*, gathered at Copped Hall, Totteridge, Herts, where it grows in quantities over a space of about two acres in the middle of the park.—EDWIN FASCOBERT, *The Nurseries, Fulham.*

Dewdrops on Vine Leaves.—I have noticed my Vines with a drop of clear fluid depending from the point of nearly every leaf. Will some of your correspondents inform me if this is dew, or a natural exudation from the leaves? My gardener tells me that he has observed the surface of the leaves quite dry while the edges were sustaining these pearly drops. The house was dry, and there are no signs of leakage.—J. H. W., *Faringdon.*

Barren Fruit Trees.—Can any one give me any information respecting fruit trees which I cannot induce to fruit? Eight years ago I planted four dozen, viz. Apples, Pears, Plums, and Cherries. The second year I had a little fruit from some of them; two years afterwards I had none. I have had them lifted twice and found the roots in good condition and no tap roots. Part of them form an orchard, and others are on wire espaliers, 6 in. from the wall, south and south-east aspects—the latter being Plums and Pears. I have never had any fruit except once from the Pears. The Plums grow vigorously until about the middle of August, when they appear to suffer from some cause or other. I have also two *Jargonelle* Pears, one at each end of the house; one has been planted about 30 years, the other 15 years. They cover a space of about 50 ft. by 40 ft., they have been spurred back, and are very symmetrical, but they bear no fruit, except here and there at the extreme ends of the branches. I have had them root-pruned twice. The subsoil is clay.—STOCKPORT.

Name of Plant.—T. P., Finchley.—*Diplacis glutinosus*.

Plant-lore of Shakespeare.—Would "Christine" kindly favour us with her address?

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWERS AND SCULPTURE.

DURING the three days of the closing of the Salon a horticultural show was improvised in the garden space devoted to the exhibition of the works of sculpture, and the blending of the combination of the fine art of flower culture with that of marble carving has been so well, indeed so artistically managed, that the sculpture court is one of the prettiest sights in Paris; everyone is regretting that it is only to last three days. Large flowering shrubs were disposed at the angles so as to produce a charming background of various tones of green and brown to the statuary in their immediate neighbourhood, and in front ornamental-foliaged plants of lower growth, a great variety of the new white *Hydrangea* playing a conspicuous part. The *Caladium* family was splendidly represented, several new varieties being very remarkable, especially one with leaves of rosy-white nearly as transparent as glass, with rich carmine veinings, which become deep green at the edge of each leaf, named *Perle du Brésil*, and another *Louise Duplessis*, of various tones of rich crimson, most richly veined and mottled with velvety green; the collection of bronze-leaved *Begonias* was equally varied and fine. Among what horticulturists call florists' flowers the finest and most numerous collection was one of herbaceous *Calceolarias*, exhibited by M. Roi, the gardener of Madame Schachler, of Belleville, a truly noble representation of that attractive tribe, many of the new seedlings being of unusual size and of an exquisite symmetry both of form and markings. An exceedingly grand and almost exhaustive representation of the *Cactus* family and its allies occupied a conspicuous position. But to return to florists' flowers: there was a fair show of Zonal *Pelargoniums* (double and single), not show plants, but among them were some remarkably fine varieties, most of which however bore English names, a sign that we are not behind our clever neighbours in that branch at any rate:—A double white, *Aliee Sisley*, the flowers in the centre of the mass being deep rose; *Madame Anclie Baltet*, a very clear white, and fully equal to *La Perle des Blancs*, were admired by connoisseurs; *Madame Barroyer*, half double, rosy-vermilion; and *Guillion Mangilli*, a large-flowered, semi-double variety, of a deep cherry colour, forming a grand truss of great size, was evidently a great favourite. Among the scarlets *Delleport* was remarkable, having the largest and broadest-petaled flowers I have ever seen; *White Pelleport*, a grand pale scarlet; and *Duplessis*, a rich and extremely dark maroon-erimson, was a novelty in colour that is sure to be sought for. Among a tolerable collection of *Verbenas* *Azone*, a pale bright purple, with an extremely broad white eye, produced almost the effect of a *Primula*, and the same may be said of *Anais*, a very deep blackish-purple with an equally broad white centre. Among a selection of *Begonias* of the *Boliviansis* strain, was a grand, unnamed seedling, with flowers as brilliantly toned as those of the original parent, and twice the size of any I have yet seen; it is really a grand acquisition, especially if hardy enough for the open garden. The *Clematis* display, in comparison to our own shows, was exceedingly poor. A very extensive collection of hardy annuals and biennials was shown by the Messrs. Vilmorin, which attracted a crowd of enthusiastic amateurs and garden lovers. Among the conspicuous ornaments of the collection were *Kauffussia amelloides*; the dwarf yellow *Tagetes*, a veritable tuft of gold; the pretty little *Gilia liniflora*; the Giant White Candytuft; a grand variety of *Chrysanthemum Drummondii*, with flowers nearly 3 inches across, in fact, almost Sunflowers; and many pretty garden Grasses, especially *Lagurus ovatus*. The *Silene* group was chiefly represented by the maroon-calyxed *S. ruberrima*; but the gems of the whole collection were the symmetrically-flowered *Clintonias*, each grand tuft suggesting the idea of enamelled jewellery—this was evidently a lady's favourite, for in front of each tuft was such a dense group of lady admirers that amateurs of the sterner sex, even with such elbow

pressure as was occasionally attempted, had no chance of a near view. Messrs. Vilmorin had also a fine display of Japanese *Primulas*, several of which were remarkable for fine growth and grand trusses of flower; one especially, with blooms of richest crimson, culminating into dazzling carmine in the centre, was evidently appreciated highly by *Primula* fanciers. But to me, after all, the most attractive feature was the show of *Pansies*, the culture of which truly lovely flowers has been made a speciality by several clever cultivators in the neighbourhood of Paris and other parts of France. They grow nothing else—their flower domain begins and ends in *Pansies*; and the results of this concentrated energy directed to the culture of one genus and its varieties only are simply splendid: the enormous size of the flowers, nearly double that of the best English varieties, is not the only excellence attained; the immense varieties of colour, from nearly black and rich velvety brown, to tones of positive crimson, and through a series of pink tones to rosy white, are striking in the extreme; the markings, too, of some of the varieties are, florally speaking, of a truly grand character, the three lower petals being massively blotched with tones of colour differing from that of the upper petals, and sometimes all five petals equally blotched with the same colour. The French test of excellence does not appear to be mere flatness of face and circularity of outline, but size and symmetry of flower, sufficiently open for full display of colour, and above all, the tones of colour, among which the tints approaching crimson and pink appear to be very favourite ones. A *Pansy*-grower at Chalons exhibits a collection of striped varieties and no others, some of which are really splendid. Such a display as that of the flowers and sculpture of the art garden of the *Palais de l'Industrie* is rarely to be seen. I have been again and again; it is now closed, and the ordinary plant decoration with which the French never fail to heighten the effect of their exhibitions of sculpture is all that remains.

Paris, May 30.

NOEL HUMPHREYS.

FOXGLOVES IN THE WILD GARDEN.

WERE this not a common British plant, it would doubtless be oftener found in the shrubberies and borders of our gardens than it is; but too many condemn it because it is abundant in our woods and hedgerows. Of all wild plants few are more at home in the wild garden than the Foxglove; it reproduces itself freely from self-sown seed, and it is one of the most useful summer decorative plants for woods or other unkept places. It would be, however, a sad mistake to confound the Foxglove of the florists with the common *Digitalis* of the woods, for although the former does not differ from the latter in habit, yet, in a decorative point of view, it is far in advance of it; it has much longer spikes of flower, more variety in the way of markings and tints of colour, and the blooms are larger than those of the common Foxglove. Seeds of the Spotted Foxglove, sometimes called *Digitalis gloxiniaeflora*, may generally be bought true to name. They should be sown in a pan or box in a cool house or frame in May, and even if there be no glass at disposal it is best to sow them in that way, as the seed is so small that should it germinate during the night and get roasted up by the hot sun during the day, the young plants would be inevitably killed. Plants raised in pans or boxes, when well in rough leaf, should be pricked out in a shady spot and kept watered for a few days, but once fairly rooted they will need no further attention until the autumn, when they may be lifted and planted out in the borders. The Foxglove, being a biennial, flowers the second year, and the stronger the seedlings planted out the finer will be the blooms. The colours of the spotted forms of the Foxglove range from the purest white to deep red, the intermediate shades of pink especially being most pleasing; the spots or blotches are all placed inside the throat of the flower, and are generally purple, crimson, or maroon. On strong, robust plants it is not unusual to find spikes of bloom 4 ft. in length, almost rivaling the *Hollyhock* in stateliness and beauty. A by no means common Foxglove is *Digitalis lutea*, a true perennial, with foliage usually a pale green, and more pointed in form than that of the biennial section; the flowers, too, are smaller than those of the class just referred to, and of a somewhat dull

yellow colour, slightly spotted with brown. As a hardy border plant, which can be propagated either by division or by seed, it is well worth cultivation. Two years ago I endeavoured to secure a cross by hybridizing the flowers of this kind with pollen of a biennial variety, but out of the produce one plant only has given evidence of change that has the habit and robust growth of the spotted forms with the peculiar leaves of the *Digitalis lutea*; I therefore look forward with interest to its blooming, in the hope that a genuine hybrid has been produced. To those who have extensive woods or wild gardens under their care, it may be worth while to point out that it is possible to beautify these largely by the sowing of seed of the spotted Foxgloves indiscriminately here and there, especially in spots where it is likely a foothold will be obtained by the young seedling plants. Although it is possible that the kinds thus grown may degenerate in time, yet it is easy always to grow a few under garden cultivation, and thus yearly secure an abundance of seed to grow in the woods and keep the strain true.—A. D.

HARDY AMERICAN AZALEAS AT HOME.

Among the hardy foreign plants that have been domesticated in England is a group of flowering shrubs, somewhat allied in character, which have been imported from America, and given, on account of their distinguished qualities, the appellation of American plants. They are nearly all evergreen, and celebrated alike for foliage and flowers. An exception to this rule, however, is found in the hardy or Ghent Azalea, the leaves of which are entirely deciduous. The Rhododendron, from the frequent exhibition of its beauties in a most effective way, has attained quite general recognition, but the hardy Azalea, so well fitted to rival the charms of its relative, receives less attention. It is not, therefore, to be expected that the points in which it excels the Rhododendron should be properly appreciated. The term American plant is very judiciously applied, on account of the numerous forms assumed by *Azalea viscosa*, *nudiflora*, *calendulacea*, &c., in their haunts amid American woods and streams, but the species is really by no means confined to this continent. The single variety *A. pontica*, suggesting Mediterranean nativity, has attained a very extended employment throughout Europe, producing by cross-breeding, chance and otherwise, many of the finest yellow-coloured flowers. All the varieties of *A. pontica* are, however, ill-adapted to the climate of America, suffering more or less injuries in the bud from cold. This peculiarity of *A. pontica* explains certain complaints that are sometimes heard concerning an alleged defective hardness of Ghent Azaleas generally. Unquestionably the best forms are our native varieties, and few are finer and of sweeter odour than the large *A. viscosa* that grows in certain parts of the South. *A. nudiflora* is less beautiful, yet shows fine pink tints. It is very hardy, and plentifully distributed throughout the country. *A. calendulacea*, a native species with delicate orange tints, is also very hardy. As a late white variety of sweetest odour, nothing we know of can surpass *A. viscosa*, both for refined beauty and great hardness. It is quite desirable that the larger forms of this Azalea should be specially propagated. Amid the uncertainties attending the growth of many imported varieties, tainted as they may be by cross-breeding with *A. pontica*, it is important to know that we have among the hardy varieties of this country two forms in the *A. calendulacea* and *A. nudiflora* capable of producing the very finest combinations of colours—scarlet, crimson, and orange shaded on the same petal. It is strange that two or three simple primitive forms should alone make up the apparently endless varieties in the trade with their rich combinations of form and colour; indeed, if the Rhododendron may be termed the king of American plants, the hardy Azalea should certainly be the queen. Japan, from a flora specially adapted to America, is sending us the last and finest development of hardy Azaleas. They have been given the name of *A. mollis*, and possess the largest and most showily-tinted Azalea flowers yet seen. In landscape gardening the hardy Azalea may be effectively massed in groups by itself, or appropriately fringed about the outer edges of Rhododendron beds, producing a shading that relieves the more abrupt and larger outlines of

the Rhododendrons. For solitary prominent positions it is less fitted, needing some background for its slow growth and subtle colouring. Little pruning should be employed, and that only to establish the native and peculiar layer-like arrangement of foliage and twigs. The leaves have a bright cheerful green, except the *pontica* varieties, which acquire a rusty hue during midsummer. The roots are always fibrous, and very easily transplanted. In summing up the merits of this plant, we are constrained to claim for it at least equal rank with any hardy shrub grown in all the grand essentials of vivid, varied colouring, hardy, compact growth, and healthy, long-lived nature.—S. PARSONS, in "Country Gentleman."

Mr. J. Van Buren (of Habersham Co., Ga.), commenting on the above, sends some interesting notes to the same paper, Azaleas abounding in that part of the country. The forms of *A. calendulacea* grow here to the height of from 10 ft. to 15 ft., and are of every conceivable shade and colour, from the palest yellow up through golden to orange, and thence on to scarlet and crimson and variegated. They frequently cross with *A. nudiflora*, having some of the petals of a pink or rose colour, and the others of some shade of orange-yellow or red. We have one growing by the side of the porch of our house, some 15 ft. high, and 10 ft. or more in diameter, which annually has myriads of flowers. It is now in all its glory. I send you some flowers; one petal yellow, and four of a shade of scarlet. The scarlet and crimson varieties are probably the most beautiful, the colours being very brilliant. It is rather a difficult matter to transplant them successfully, as they have in their wild state very large, uncouth roots, caused by the annual burning of the woods, which kills the tops down to the ground. This does not injure the roots, which continue to grow and send up new shoots; but the roots have very few fibres. I have endeavoured to find young seedlings, but have never succeeded, nor have I ever known any one else to find any. They produce an abundance of very fine dust-like seeds, but I have never tried sowing the seeds. *A. viscosa* invariably grows on the margins of water-courses, where it can have its toes in the water. Its flowers are pure white and very fragrant, with the odour of Cinnamon or Cassia. It blooms in June, while *A. nudiflora* and *A. calendulacea* flower in April and May. *A. viscosa* frequently blooms twice in the same summer. At this time our forests are all aglow with the endless variety and brilliance of their colours, and as soon as their season is over Rhododendron *catawbiense*, *R. maximum*, and *R. punctatum* take their places.

Hybrid Primroses.—In connection with the enquiry of "W. T. B." and your reply thereto (see p. 392), I send you the following dimensions of an Oxlip, found by Mr. Little between Sevenoaks and Tonbridge during last week. Both Primroses and Cowslips were plentiful close by; and some of the Cowslips measured $\frac{3}{4}$ in. across the corolla. This Oxlip had three peduncles, varying from $6\frac{1}{2}$ in. to $7\frac{1}{2}$ in. in length, each having a truss of bloom at the top, in addition to which there were twenty-three stems, each about $2\frac{1}{2}$ in. long and each bearing a single blossom. One of the stems with trusses had eight flowers, another nine, and the third had twenty-two flowers. None of the blossoms were less than 1 in. in diameter, and one measured $1\frac{1}{4}$ in. across. The leaves were proportionately fine.—W. T. T.

Alstroemeria aurantiaca.—A patch of this in my garden has grown too large for its situation, and so I sowed another lot of seed, and dug up all the old roots, fondly imagining that I had utterly eliminated it, and to my dismay and annoyance it has now come up thicker and stronger than ever; every fragment of tuber must have grown. This is new to me, for I always imagined that this group of plants required a crown to grow from.—JOHN E. DANIEL.

Decoration of the New Edinburgh Vegetable Market.—At a meeting of the Public Parks Committee of Edinburgh Town Council last week Mr. M'Leod, superintendent of the city parks and gardens, submitted a sketch of a design which he had prepared for the decoration of the top of the new vegetable market. Mr. M'Leod proposes to place a number of vases on the projecting pillars, and to fill them with flowering plants during summer, and with evergreens in winter. Numerous garden plots are also to be placed on the roof, and the beds to be laid out in an artistic manner.

Hyacinthus amethystinus albus.—Some time ago a correspondent sent me a small parcel of seed of this lovely bulb; this year it has for the first time produced seven spikes of bloom, six of these are of the normal or blue colour mottled with white, and one only pure white; but from the foliage I rather fancy two, if not more, will another year prove white. I judge so from the circumstance of the one example now in flower being narrower in the foliage than the blue ones.—JOHN E. DANIEL.

NOTES OF THE WEEK.

A FINE OAK AND ITS INHABITANT.—Sir Charles Isham sends us from Lamport Hall the photograph of a very fine Oak there. It is 27 ft. in circumference at 4 ft. from the ground, and is very picturesque in form. It is the finest Oak within sixteen miles of Lamport, and is otherwise remarkable on account of its being inhabited by a fox, who makes his house net at the base, but 30 ft. up the stem of this giant tree. He runs up the stem from branch to branch and has a window as well as a hall door, through the former of which he may occasionally be seen peeping.

APRICOTS IN COVENT GARDEN.—We have for some years past been in the habit of receiving large importations of very small Apricots in May from Spain; they have hitherto been of a dry, woolly texture, and, as a matter of course, with little or no flavour; this year, however, they are of fair size, well coloured, and excellent in flavour. They are packed firmly in small wooden boxes, each of which contains about two dozen fruit. The best samples now realise from 3s. to 3s. 6d. per punnet of twelve fruits, or 6s. per box.

TWICKENHAM PURPLE STOCK.—While most people seem to prefer double flowers, many of them far from lovely in form, I am odd enough to prefer single ones, and among them I like this single Stock, because it is single, free, and hardy enough for walls, rocky banks, or the wild garden or shrubberies, and also because it has a fine Clove scent.—H. H.

ASPARAGUS.—Notwithstanding the great increase in the area devoted to Asparagus culture, it always remains a dear commodity, even when the quality is very inferior. The very finest large samples (mostly French) fetch nearly or sometimes quite 6d. per stick.

PROLONGING THE LILAC SEASON.—The harsh treatment Lilacs have received from the weather this year should turn attention more than ever to their culture in pots; nothing is more profitable. The smallest garden should have Lilacs in pots. It has lately been proved that they may be flowered easily in a room without the aid of a forcing house. In this way the season of these sweet flowers may be greatly prolonged, and the flowers are often better indoors in March than in the garden in a harsh May. The French sometimes work them on a dwarfing stock, one of the Privets.

MASDEVALLIAS IN MAY.—These easily-grown and charming Orchids, though nearly always in bloom, are never so beautiful as in May, when abundance of light and fresh air can be admitted to the plants. In a small span-roofed house in Messrs. Veitch's nursery may now be seen probably the finest display of Masdevallias to be found in the country. The plants are grown in pans and small pots, some of which bear no fewer than twenty-five to thirty blooms and buds; altogether there is in the house in question little short of 300 fully-expanded blossoms of the richest colours. M. Veitchi and M. Harryana are the chief kinds now in bloom, and the large, bright orange-purple-shaded flowers of the former contrast effectively with the varied rich, brilliant rosy-purple of the latter.—S.

THE HOOP-PETTICOAT NARCISSEUS AS A POT PLANT.—During the past week Messrs. Hooper & Co., of Covent Garden, have sent us a beautiful tuft of this species (*N. Bulbocodium*) growing in a 5-in. pot, and bearing twenty-five flowers. As to its beauty as a decorative plant there can be no question, and that it is not more frequently grown in pots as an "everybody's plant," or for market, is doubtless due to the difficulty that exists in obtaining bulbs of it. Few hardy plants rival this in brightness, and the golden colour of the flowers is heightened by the fresh tufts of green, Rush-like leaves amid which they so easily nestle.—B.

IRIS ROBINSONIANA.—This (the Wedding Flower of Lord Howe's Island) is now in cultivation in the Victoria Nurseries at Holloway. It is a gigantic species, attaining a height of 6 ft., with sword-shaped leaves in proportion, and large, pure white flowers marked with golden-yellow on the outer petals. The flowers are about 4 in. in diameter, and very evanescent, but as they are numerous and quickly succeed each other, the plant retains its beauty for a long time, and is said to be one of the most beautiful species. It is a native of Lord Howe's Island. Lovers of curious plants will be glad to add it to their collections, bearing in mind that it requires stove or warm greenhouse culture. We hope soon to hear of its flowering in this country.

CALCEOLARIAS AT READING.—The Calceolarias at Messrs. Sutton & Sons, Portland Nursery, Reading, are just now beautifully in bloom, and should be seen by all who take an interest in this class of plant. The strain is one of the finest, being the result of years of careful selection. Many of the individual flowers measure 2½ in. across, and are perfect in shape, and of almost every conceivable

colour. As to the plants they are marvels of good culture, averaging about 18 in. height and almost as much in width, and they may be counted by the hundred. They are not for sale, but for seed-saving purposes. The nursery generally, though but of small extent, is one of the best managed in the country, and is well worthy a visit at any period of the year, but especially so at the present time.—W. W. H.

FINE ENGLISH ASPARAGUS.—Some Asparagus has been shown us (grown by Mr. A. J. Harwood, St. Peter's Cottage, Colchester), which is by far the finest we have seen grown in this country. Mr. Harwood described his practice in THE GARDEN, at p. 477, Vol. X. The bunch above alluded to was shown at Colchester on the 24th ult., and was awarded a first prize.

GREEN PEAS IN COVENT GARDEN.—June 1 should always be looked to by the Duke of Bedford if he would not lose his Covent Garden charter:—"On Thursday a peck of Green Peas was sold in Covent Garden Market for 6d., agreeably to an ancient custom, the charter being held by the circumstance of selling at that price on the 1st of June."—"Morning Intelligencer," June 31, 1780.

BLUE FLOWERS IN THE MARKET.—The most effective blue flowers now to be seen in the florists' shops in Covent Garden are those of the Cornflower (*Centaurea Cyanus*). They are much used in bouquets amongst white flowers, to which their dark blue colour forms an effective contrast, and reminds us very much of a similar blue flower which is largely used for the same purpose in the autumn, viz., *Stokesia cyanea*.—S.

HARDY TREES AND SHRUBS AT KEW.—The tree growth at Kew is just now especially worth notice. Among flowering kinds the Judas Tree (*Cercis Siliquastrum*) is very ornamental, its nearly leafless branches being clothed with purple buds and flowers. The Red Chestnut (*Pavia rubra*) is another effective, early, summer-blooming tree, as is also its more stately relative, the Horse Chestnut. Rhododendrons are everywhere most brilliant, and Magnolias, double-blossomed Cherries, Pink and White Thorns, Laburnums, Wistaria, and Berberis Darwini are at their best.—B.

MADRESFIELD COURT GRAPE.—Fine examples of this excellent Black Grape are now exposed for sale in the Centre Avenue, Covent Garden, the produce of Vines grown at Isleworth; the bunches are of average size, the berries very large and covered with bloom, and for the time of the year perfect as regards colour. As a late kind this is considered by market growers to be of little use, as it does not keep well, but as a summer Grape it has for some time been considered the best kind brought to market, and in a very short time we expect to see it become almost as popular as an early variety as the Black Hamburg. Excellent as this latter kind is well known to be, the Madresfield Court, on account of its rich Muscat flavour and noble appearance, is greatly preferred by consumers of Grapes, and frequently fetches higher prices than any other kind.—S.

INJURIOUS INSECTS.—The Society of Arts has convened a special meeting of agriculturists for the 5th inst., to discuss the question of stamping out hurtful insects, which was raised by a recent circular from the Lords of the Privy Council to the different agricultural societies throughout the kingdom, in which circular certain propositions made by Mr. Andrew Murray were brought under notice. The Duke of Buccleuch has consented to preside, and the discussion is to be opened by the reading of a short paper on the subject by Mr. Murray.

A NEW PARK AT PAISLEY.—On Saturday last, the inhabitants of Paisley held a demonstration, on the occasion of the opening of a public park—a gift to the town by a deceased citizen, Mr. Robert Brodie. The park is situated at High Carriagehill, in the southern part of the town, and extends to about 22 acres. Its value is estimated at £16,000, and during the past year or two the Town Council have expended about £2800 in laying it out and ornamenting it.

GIFT OF A PARK TO FALMOUTH.—A great public demonstration took place the other day at Falmouth on the occasion of the presentation of a small but well laid-out park to the town by Lord Kimberley. An address was presented to his lordship, which, among other things, spoke of his services as a statesman. Lord Kimberley replied that he was pleased that he had gained the approval of his fellow citizens. He then referred to his gift of the park, and said that when sitting as a member of a committee in the House of Lords, he had heard witnesses assert that provision for innocent recreation would tend to check crime. He then handed to the authorities the deeds of the park, and said that, with the consent of the new proprietors, he intended to erect a lodge at one of the entrances. The park, which has been planted and beautified by his lordship, is picturesquely situated in Berkeley Vale, diverging from the town westward.

EARLY SOWING OF VEGETABLE SEEDS.

THIS season has afforded abundant proof of the disadvantage of sowing seeds of culinary crops out-of-doors too early. Beds of Leeks, Brussels Sprouts, Savoys, Cauliflowers, &c., were sown here during the first week of April, and the plants are in an equally forward and more healthy condition than the produce of beds sown with the same kinds of seeds early in March. This season has hitherto been exceptionally unfavourable for plant growth, and the advent of such permanent crops as Asparagus has been quite a month later than is usually the case. Taking the seasons generally, however, the first week of April is sufficiently early the seeds of the various varieties of the Brassica tribe and other culinary vegetables in the open air. True, our seasons are if anything too short for the thorough maturation of some crops; and consequently their seeds should be sown as soon as that operation can be performed with anything like advantage; and also on account of an undesirable interregnum, which it is necessary to avoid as much as possible between the autumn-sown crops of Cauliflowers, Lettuces, &c., and those sown early in spring, with the view of succeeding them. In the case of such crops it is best to sow a small portion under glass, on a slight bottom-heat, if that can be secured; or enough of such plants as Lettuces and Cauliflowers to keep up a continuous supply may be obtained by sowing a mere pinch of seeds in a pan or box early in March, and placing them in any heated glass structure. The young plants should be pricked out when large enough to be handled into other boxes or pans, gradually curing them to exposure in the open air, and in due time taking advantage of favourable weather to finally plant them where they are intended to produce a crop. Even Onions, Peas, Beans, French Beans, &c., are frequently sown too early out-of-doors, and portions of these might be treated as has just been recommended with advantage. The first supply of all such crops as Radishes and early Carrots should be sown under glass, on a slight hotbed composed of fermenting stable manure and tree leaves, so as to produce a slight amount of bottom-heat, which will be found sufficient for the purpose. Where this can be obtained by means of hot-water in the form of pipes or tanks, much litter and labour will be of course obviated. In all cases, however, where plants are raised from seeds sown under glass at an early period of the year great care is necessary to prevent etiolation, to obviate which air should be admitted on all favourable occasions, taking care to prevent the plants from being exposed to cutting draughts of cold air. The seeds of some culinary plants are naturally much longer in vegetating than others, a remark which applies to Parsley for example, the seeds of which will remain in the soil when at a low temperature for a considerable period without having their germinating powers in any degree deteriorated; the length of time, indeed, during which some seeds will retain their vitality is very considerable, especially when buried beyond the reach of atmospheric influences. The case, however, is entirely different where seeds are sown in the usual way, but at too early a period; under such conditions their vegetating powers often meet with many injurious checks, which too frequently result in the production of weak and debilitated plants, which are for a much longer period subjected to the attacks of insects and other maladies to which plants in a young state are liable than the produce of seeds sown when the soil is at a higher temperature, and when the early progress of the plants is consequently more rapid.

P. GUILVE.

Culford.

FRUIT CROPS NEAR LONDON.

A MONTH or six weeks ago the fruit orchards around Isleworth, Chiswick, and Kew, presented a beautiful appearance. The Pear, Plum, Cherry, and early Apple trees, were laden with snowy white or rosy-tinted blossoms, and fruit-growers were congratulating themselves that this year at least they would reap a rich fruit harvest. On visiting the Isleworth orchards, however, this week, we find that not only has the bloom disappeared, but the trees are left in many instances almost fruitless. Wall trees, espaliers, and standards have fared much alike, and especially is this the case with Pears. Large trees of the common Hazel Pear may be found fairly loaded

with fruit, but all the choicer sorts, such as Marie Louise, Williams' B'n Chrétien, Jurgonelles, &c., are a complete failure. Mr. Wilmot, who has upwards of 100 acres of fruit trees, states that he has never before seen Pears a greater failure. On long rows of espalier trees of the new Pitmaston Pear, scarcely more than a dozen fruit can be found. The common varieties of black Plums have fared a little better, but these have also suffered greatly in some places, and the more tender kinds will not yield above half a crop. Early Apple trees are a complete failure; but let us hope that the later kinds, which are just now in bloom, may bear a good crop. Cherries appear to have set pretty freely, but many of them have turned yellow, and will drop off. Morellos, grown as standards, are in some places well laden with fruit, which at present looks healthy. As regards bush fruits, Gooseberries and Currants under orchard trees are fairly well furnished with berries, but in open quarters these appear to have suffered very much from the east winds which we have so long experienced. Strawberries appear to be setting tolerably well, but they look stunted both in growth and bloom. Market gardeners, who are fortunate enough to have good vegetable crops under their orchard trees, will have some compensation for their loss, but people who are entirely dependent upon the fruit crop for a living will suffer severely this season.—C. W. S.

New and Rare Orchids.—In Messrs. Veitch's nursery at Chelsea may now be found several new Orchids, as well as some finely-flowered plants of older kinds. *Cypripedium Domini* is now furnished with five strong flower-spikes, each of which bears from three to five blossoms; this *Lily's-slipper* is a hybrid raised by Mr. Dominy, from a cross between *C. Pearcei* and *C. cordatum*, between which varieties it is intermediate. *Cattleya Skinneri alba* is a new variety now flowering for the first time; its flowers are of the purest white, and it promises to be equally as floriferous as the type. *Dendrobium Rhodostema* is also flowering for the first time; it is a hybrid obtained by Mr. Seden between *D. sanguinolentum* and *D. Huttonii*; its flowers, which are larger than those of either of the parents, have white, rich, purple-tipped petals and a delicate yellow throat, and when well established it will doubtless be found a valuable addition to our list of Dendrobies. *Vanda Parishii*, a rare plant, is likewise now in flower; it bears strong spikes of greenish, brown-spotted, cup-shaped, drooping blossoms, which are very powerfully scented; and a specimen of the better-known *Laelia Wolstenholmia* is bearing twenty-one very large and magnificently-coloured blooms.—C. S.

Churchyard Gardens.—Allow me to call attention to the efforts being made to render our once neglected churchyard (St. John's, Waterloo Road) a London garden. We have a row of trees some forty years old around the boundary walls—Planes, I believe—and we have recently removed all tombstones, levelled and turfed the ground, and laid out paths at an expense of some £100, raised entirely by voluntary subscription. Messrs. Waterer, Sutton, Carter, and others have given us valuable selections of shrubs and seeds, but we have room for much more. I would suggest that this is an excellent opportunity of testing the relative merits of the various kinds of town trees, and that we shall be happy to receive shrubs and young trees of any kind, giving them the specified attention which their donors may recommend. As this is an undertaking solely for the public benefit, and from which no one concerned will reap the smallest pecuniary advantage. I trust that any notice which may be taken of it will attract the attention of those who have suitable shrubs at their disposal, and that we may receive valuable assistance in furnishing our now empty beds. Whilst writing, I have to acknowledge the liberality of Messrs. Green, of Blackfriars Road, who have sent us a very useful lawn mower.—WALTER WOOD, Hon. Sec., 87, Waterloo Road, Lambeth.

Early Cabbage.—The following sorts have been, and still are in excellent condition, this season being more favourable for succulent, moisture-loving crops, than for those that delight in strong solar heat. Little Pixie and early York planted in it, apart from a sheltered border with a south aspect were very useful during February and March. And during April and May the following sorts on open kitchen garden quarters have been excellent, viz., Early Champion, Early Fulham, Early Battersea, and Enfield Market. These are all first rate sorts for general purposes.—J. GROOM, *Lebanon*.

Frame Potatoes.—The late frosts will necessitate the supply of new Potatoes being obtained from under glass or some temporary protection until quite late in June. Having tried several kinds of Potatoes under glass, I should still adhere to the Ash or Walnut-leaf type of Kidney for earliest bearing, as it produces a small quantity of haulm and tubers, and matures them quickly. But if time be not of importance or the crops intended for use during May and June, I find some of our old-fashioned second early kinds much more prolific and quite equal to the Ash-leaf in quality—a good number of even-sized tubers is preferable to extremes either one way or the other.—J. G.

THE LIBRARY.

GARDEN INSECTS.*

THE issue of a work on "Economic Entomology" by a Government Department is sure to raise among all interested in gardening operations, the questions—what can it tell us that is of use to us? and how is it that a Government Department has come to take the matter up? We will say a few words about the second question first, and it will be noticed that it is the outcome of work originated by horticulturists. As far back as 1868 the Royal Horticultural Society commenced the plan of

Fig. 1.—Phytoptus.

Fig. 2.—Head of Phytoptus.

preserving the specimens of Insect damage sent to its scientific committee in order to obtain its advice. They decided on making a collection that should be of practical use, including specimens of Insects that are injurious to horticulture and

Fig. 3.—Volvulifex Aceris.

agriculture, together with examples of the damage done, the object being to afford cultivators an opportunity of becoming acquainted with the appearance and habits of the enemies from whose ravages they suffered. The collection rapidly grew, and the Society applied to the director of the South Kensington Museum for room in which to put it; this was granted, and as

the collection still further grew, the Science and Art Department was found willing to take it altogether under its care, and so it was handed over. Grants of money for the development of the collection were made, and Mr. Andrew Murray, was appointed to the control of it, not on the staff of the Museum, but as scientific referee. The collection as it is now arranged is entirely Mr. Murray's work. The Department may justly be proud of it, for there is no collection, having the same objects, equal to it on the Continent or anywhere else. The Handbook is prepared by order of the Lords of the Committee of Council on Education, and it is stated that it is "the first of a series of Handbooks intended to serve in the first instance as guides to the different branches of the collection of Economic Entomology; and in the next place, as practical treatises on the subject for the use of the public generally." That is how it has come to pass that a work on "Economic Entomology" is brought out under the auspices of a Government Department.

Before speaking of the book itself, it will be well to say a few words about the collection to which it forms the guide; for although the work is amply illustrated with woodcuts so that it can be used by itself as a text-book, yet, for a practical acquaintance with the subject, there is nothing like a study of the collection itself. Mr. Murray's aim in his method of arrangement has been to give as much instruction as possible with the least trouble to those seeking it. His plan has been

Fig. 4.—Cephaloneon myriauleum on Maple leaf.

to use glazed frames, which are hung on screens as pictures. In the frames are not only specimens of insects and insect damage, but beautiful water-colour drawings from his own pencil, showing the magnified appearance of the objects exhibited. These drawings may indeed be almost said to constitute the collection, for without them its practical use would be but little. In scope the collection embraces the entire range of the ways in which Insects affect man in his material interests—the way in which they damage his industries and interfere with the comfort of himself and his domesticated animals, and the manner in which he can put them to a profitable use.

Now we turn to the question of the direct use of the collection and the book in relation to horticulture. Many of the cases are occupied with sections of branches and trunks of trees, showing the way in which timber is injured by boring insects; there are also illustrations of the ways in which leaves are damaged by Saw-flies and Gall-makers. Other suites of cases are occupied with objects which illustrate the damages to fruit trees, to our flowering and ornamental trees, to Cabbage, Potato, Carrot, and Turnip crops, and other garden produce. The Insects that do these damages are, for the most part, too small to be identified by the unassisted eye, and hence the great value of Mr. Murray's magnified drawings. It would be a useful plan for the Department to adopt to have the drawings copied by some of the most experienced students in its art schools, and to have sets of these distributed among the larger schools in agricultural districts. It may

* "Economic Entomology (Aptera)." By Andrew Murray, F.L.S. London: Chapman & Hall, South Kensington Museum Science Handbook, published by order of the Lords of the Committee on Education.

seem needless to urge again, since it has been so often urged before, that horticulturists and agriculturists should be trained in a knowledge of the insects that damage garden and field produce. Sixteen years ago Mr. Curtis, after a long experience, wrote as follows:—"It is a great mistake to suppose that scientific descriptions and correct nomenclature ought to be employed for the use of those only who are specially employed in the study of natural history. If insects

Fig. 5.—Leaf of Plum tree, with Galls of *Volvulifex Pruni*.

be not thus accurately and scientifically described, and their names carefully learnt, the facts noticed by practical observers are generally worthless, and may tend to mislead by the confusion of one species with another, and the consequent adoption of improper remedies. . . . A very large amount of the information given by practical agriculturists and gardeners has proved valueless in cases where, if the particular species alluded to could only have been identified, it would have been of great value in furthering subsequent investigations." These ideas have been urged over and over again, still nothing has come of all the talking and writing; "practical" gardeners remain as ignorant of the subject as they were twenty years ago. It is to be hoped that this collection of the Science and Art Department will prove

Fig. 6.—Twig of Plum tree, with Galls of *Volvulifex Pruni*.

the inauguration of a new era in the spread of this kind of knowledge connected with horticulture and agriculture. It is of little avail that the information is placed within the reach of the public in one London Museum; it must be spread far and wide. One most effective means of doing this would be through the schools of the country, where subjects are taught in connection with the examinations of the Science and Art Department. It is well known that the naturally observant habits of children can be turned to good account in teaching them about flowers and insects. The late Professor Henslow showed how easy it was to enlist the interest of children in the study of botany, and at the

Exposition des Insectes Utiles et des Insectes Nuisibles, held in Paris last September, there were exhibited from rural schools throughout France specimens of drawing books and copy books done by children, which contained sketches of those features of insects by which they might be recognized, with descriptions of their depredations and of their habits. If in England there were copies of Mr. Murray's drawings distributed among schools and a little encouragement given to the study, there can hardly be a doubt the children would take it up readily. It would add an interesting subject to their studies, and those who, when grown up have to do with gardens or crops, would be able readily to understand practical instructions how to deal with their insect-foes, and to give an accurately intelligible account of their own observations.

The volume of the Handbook issued contains only the Aptera, the other Orders having to be treated of in like manner in successive volumes, each of which is to be devoted to a separate Order. The present volume deals with the Myriapods, Spiders, Mites, Lice, and Spring-tails, and is profusely illustrated with woodcuts, some species of almost every genus being figured. Special attention has been paid to the Mites, and as no modern work devoted to them is in existence, it fills a blank that has long been felt. The description of the Gall Mites (*Phytopti*) that produce galls and witch-knots on trees, is a valuable contribution to the information of the horticulturist. Until a very few years ago the part that was played by these insects in making these monstrosities was only guessed at, and it is with surprise that we see the long list described in Mr. Murray's pages. These are a tribe of Mites, the largest of which are almost invisible to the naked eye, and the smallest almost invisible under the most

Fig. 7.—Section of Gall of *Volvulifex Aceris*.

powerful lens. They are named *Phytopti*, and, according to Mr. Murray, are to plants what Itch-insects are to mammals. He maintains that there is more than analogy between them; they have similar habits of life, the one irritating the skin of the mammal, the other that of the plant; they have both a transversely striated skin, they have both suckers instead of or in addition to claws on the tarsi, they have, like many of the Itch Mites, the posterior limbs atrophied and represented by a wart or hair, as may be seen in the more magnified cut of *Phytoptus*, besides other affinities. They confine their attacks to leaves either in the bud or developed; in the bud they produce first swelling and subsequently abortion, and it has now been satisfactorily proved that it is long-continued repetition of their attacks on the buds at the same place year after year that is the origin of the witch-knots that are found on Birch and other trees. It is these insects that destroy the buds of the Currant, the Hazel, and those of many other species of trees; they produce the Nail Gall on the Lime tree leaves, called *Ceratoneon extensum*; a smaller Gall on the Sycamore leaves (*Volvulifex Aceris*) (fig. 3); that on the leaves of the common Maple (*Cephaloneon myriadenum*) (fig. 4); that on the Plum tree (*Volvulifex Pruni*) (figs. 5 and 6); that on the Willow (*Ceratoneon Salicis*); and a host of others, for which we must refer the reader to Mr. Murray's book. From it we learn, too, an easy mode by which to distinguish a Gall formed by a *Phytoptus* from one formed by any other insect. Fig. 7 shows a section of the Gall of the Sycamore leaf, from which it will be seen, that while it is closed on the upper side of the leaf, it is open on the under side, and the inside is filled with hairs. Galls made by *Phytopti* have always an open entrance to it on the under or lateral side, which may indeed become narrow by the growth of the tissues, but is never obliterated.

Mr. Murray has adopted a zoological classification. It may be worth while to consider whether it would not be well to issue an index with cross references, following the plan adopted by Kaltenbach in his "Pflanzen-feinde," having a botanical classification, and referring to the particular enemies of each plant. Wherever remedies or methods of protection are known, Mr. Murray gives them, and in this lies the practical usefulness of the book.

There is one other subject connected with Mr. Murray's work on which we would say a few words. He has proposed

to the Department that arrangements should be made for united action in exterminating insects injurious to agriculture and horticulture. In bringing his proposal forward, there is one circumstance which has prevented his stating the case as forcibly as it otherwise might have been—he is not able to refer to statistics to show how great the annual losses are. We commend this fact to the consideration of those of our readers who are fond of statistics, and may have the means of compiling them in their own districts.

MYRTLES AS DECORATIVE PLANTS.

PERHAPS Myrtles have become old-fashioned; at any rate I do not think they are so commonly grown as they were years ago. To my mind they are—whether in flower or not—always beautiful, and the aromatic perfume given off by their foliage is at all times grateful and refreshing. Under even the most ordinary management they rarely get out of health, and they may be grown for years in the same-sized pots. The Myrtle is pre-eminently a cottager's plant, and when it gains a footing in a village or neighbourhood it travels from house to house in the shape of slips, until nearly every cottage window is furnished with a Myrtle. I have occasionally come across quiet back streets, mostly inhabited by working men and small shopkeepers, where Myrtle Grove or Myrtle Place would be an appropriate title, so numerous were they. I have one such neighbourhood in my mind's eye at this moment; for two years I generally passed through it several times a day, and I made the acquaintance of every Myrtle in the place, from the small stripling that was growing in the same pot with its parent, to the giant 6 ft. high that had to be placed in the back yard all the summer, and which cost almost as much care and anxiety in keeping through the winter as if it were really a member of the family, and I never now see a Myrtle in a cottage window without looking upon it as an index to the comfort and cleanliness within. Myrtles are very easily propagated; pieces of half-ripened wood, firm at the base, taken off with a heel and inserted in a pot of firm sandy soil, will root almost anywhere in a shady place. There is, of course, a certain degree of fitness in connection with everything, and plants that have made their growth in a low temperature are best propagated in a structure without much artificial heat. However, getting up a stock of Myrtles is so easy a matter that one need not refer to it at greater length.

In the decoration of the formal geometrical flower garden standard and pyramidal-shaped Myrtles might be introduced during summer with great advantage, and although there are but few places in this country where they would not require protection in winter, yet well-grown plants would be so useful for indoor decoration during that season that a stock of Myrtles of different sizes with their masses of green foliage would help to form backgrounds that would be very effective in ornamenting corridors, halls, &c. I once had charge for several years of a Dutch flower garden, very quaint and formal in its plan and keeping, and trained Myrtles, Pomegranates, and the small-leaved Oranges were largely used for summer decoration in vases, &c. Most of the plants had been used for the same purpose many years, and had been confined to the same-sized pots to suit the vases. The balls were one complete mass of fibrous roots, and might have been thrown about without a particle of soil falling from them; in fact, the soil was all consumed, and the plants must have subsisted chiefly on air and water—yet they were in perfect health. Of course, no one will suppose I am recommending the starving system for this or any other class of plants; I only mention it to show how very accommodating Myrtles are. But plants so treated seldom flower. A certain amount of annual growth is absolutely necessary for the production of flowers; and how delightful for cutting are sprays of Myrtle when thickly studded with pure white, sweet-scented blossoms! The most floriferous Myrtles I ever saw were two large, old plants nearly covering the back wall of a conservatory, and they not only flowered freely, but also fruited most abundantly. When grown altogether under glass the syringe or garden engine must be used freely on summer afternoons or evenings. Thrips are very partial to their hard, shining leaves,

and if this pest be allowed to become established on them, the beauty of their dark, glossy foliage will soon be destroyed, and the health of the plants will materially suffer. Any good loamy soil, enriched with about a third of vegetable matter, such as leaf-mould or peat, will grow Myrtles well; the pot should be well drained, as they delight in a good deal of moisture, but yet at the same time it must pass away freely. When large plants are required quickly for any particular purpose they will bear any reasonable amount of heat without injury, and in a close, moist atmosphere will grow very rapidly. Plants, with scented foliage, are likely to be in demand again, especially such kinds as can be cut freely from to mix with cut flowers.

In the arrangement of cut flowers in vases, like the arrangement of plants in groups or masses in beds, mere brightness of colour alone will not carry much weight with people of taste, unless the green setting of foliage be ample, and of a sufficiently lasting character. There are several varieties of the common or broad-leaved Myrtle, and I think two varieties of the narrow or small-leaved kind. There is also a variegated form that might be grown where variety is sought. In Ireland, and some of the milder parts of England, they will stand the winter in the open air, but, should the season be more than usually severe, they are likely to suffer to a great extent, unless placed in a very sheltered position.

E. HOBDAY.

HEDGE ROSE BUDDING.

It is no uncommon thing to find about most places some rough wild Briers in hedgerows or woods. There are two methods of converting these into Rose trees—the usual one of removing the stocks into the garden in November or December, and budding them in the usual way; and another method, that of budding them where they stand, and removing them at any convenient season, or even leaving them to bloom in their semi-wild state, which has many advantages. Supposing, for instance, that the best season for Brier planting may have been allowed to pass by; the Briers may be budded where they stand next June or July, and thus a season may be gained. Besides, the practice of budding within six months or so of the time of planting is no doubt very trying to the plants, and results in inducing a weakly habit, which is fatal to the vigour and longevity of the Rose. It seems almost certain that not a little of the disease, and many of the premature deaths, among Roses arises from the practice of budding on very imperfectly-rooted plants. The strength and vigour of the Brier shoots is no certain criterion of the size, number, or health of their roots. These shoots are more often than not the outcome of the fine roots left in the hedgerow than the natural produce of those of the current season. Hence, by the time the buds have taken, often before, there is a stoppage of supplies, an arrestment of growth, which stunts the Rose-shoot at starting or in mid-growth, and ends in permanent weakness, disease, or death. By budding Roses where they stand, in hedgerow, wood, or back of shrubbery, a good strong start is ensured. All the roots being intact, the buds take readily and grow at once, and a vigorous growth follows the first year. This is of far more importance than it may at first sight appear. There is probably not only a gain of a year's time, but one strong growth ensures another—many more. For as to growth, its character and strength repeat themselves and are far more an affair of habit than is generally supposed. Not only so, but a strong growth in Rose-shoots the first year produces strong roots the next, and these roots again find their necessary and natural expression in more, and it may be even stronger shoots the following season. If this be true, therefore—and it is—the importance of a vigorous start cannot be over-estimated, and one of the easiest and surest modes of obtaining it is by budding the Briers in the hedge-rows or places where they stand. A good many Roses might also be left in such positions with the happiest effect. The vigour and strength of Briers in a semi-wild state is marvellous at times. They seldom recover half their pristine vigour in the garden; but budded with choice Roses and allowed to remain, many of them grow with a freedom, and flower with a profusion quite unknown in Rose bed or border. In such positions, too, the plants may be left to ramble far and wide at their own sweet will. No severe pruning, no formal training should be allowed. Escaping from the knives as well as from hard and fast lines of form or size, some of the free-growing Roses, such as Gloire de Dijon, Maréchal Niel, Céline Forestier, Coup d'Hebe, Charles Lawson, Baronne Prevost, Madame Barret, and many others grow into large bushes, or run up the stems of trees, or throw out graceful sprays laden with fragrance

and beauty, far above the heads of shrubs or hedge plants, and impart a richness to gardens that nothing but Roses in a state of Nature can bestow.

D. T. FISHER.

HARDY FLOWERS IN LONDON GARDENS.

AMONGST hardy flowers now in bloom the most attractive are blue, white, and purple Columbines, *Papaver bracteatum*, with large orange-scarlet blossoms, common and Mount Peonies; blue, white, and purple Squills, and the beautifully scented double-flowered *Narcissus poeticus*; the blue *Iris germanica*, and the large, white-flowered *Iris florentina*, are just now at their best, and, where grouped together, they form an effective contrast. The stalwart flower-spikes of *Camassia esculenta*, clothed with bright blue blossoms, are strikingly

tinted blossoms, and *Romanzowia unalascensis* is loaded with white flowers. *Erpetion reniforme*, growing in moist situations, is bearing Violet-like blossoms in profusion, and *Globularia nudicaulis* is still in good condition. *Viola Delabordi* and *canadensis* are just now finely in flower, as are also some of the other kinds. *Sarracenia purpurea* is in bud, as is also *Podophyllum peltatum*. *Androsace lactiflora* is laden with pretty white blossoms, and *Erigeron bellidifolium* and its varieties are flowering abundantly. Alliums are still attractive; *Asphodelus luteus* and *A. albus* are both well furnished with large flower-spikes. *Ornithogalum*s are still in great beauty, and the purple flowers of *Muscari comosum* may be seen in abundance. To these may be added *Nothoscordum striatum*, *Aceranthus diphyllus*, and *Ranunculus*, all of which are very attractive. The beautiful rosy-purple flowers of

Cycas Normanbyana.

pretty, as are also those of the creamy-yellow-flowered variety *C. Leichtlini*, of which we spoke last week as being in flower at Kew. The Sea Thrifts, *Armeria maritima* and *A. mauritanica*, are producing numerous rose and white blossoms; and *Nepeta Mnssini* is also in full bloom; *Veronica gentianoides*, one of the oldest and best known of Speedwells, is laden with flowers, as are also the beautiful *Gentiana verna*; the bright purple-flowered *Dodecatheon integrifolium* and the white *D. Meadia* are blooming freely, as are also *Erodium*s and different sorts of *Geranium*s, notably *G. pyrenaicum*, *aconitifolium*, and *lividum*. Large plants of *Lupinus polyphyllus argenteus* are throwing up numbers of showy blue and purple flower-spikes; the Alpine Saxifrages are also very pleasing as seen growing on rockwork or on other raised positions. The dwarf *Dicentra (Dielytra) formosa* is now bearing pretty drooping rose-coloured blossoms, and the small bright golden flowers of *Milla aurea* are just peeping above the ground. *Houstonia cœrulea*, a compact-growing little Alpine plant, is producing numerous bluish-

Lynchnis viscaria splendens are now freely produced on gracefully-drooping stems, and various *Helianthemum*s are just coming into blossom, as are also *Pentstemon nitidus*, *P. confertus*, and *Collinsia bicolor*; the dwarf *Phlox subulata* and *P. Nelsoni* are still in great beauty, and associated with blue and white *Nemophilas* are very effective. *Platystemon californicum* is just now at its best, its creamy-yellow, Buttercup-shaped flowers being produced in great abundance. When the plants are grown in good soil on raised borders or to cover large stones on rockwork or similar positions, they are very effective.

***Cycas Normanbyana*.**—This fine ornamental species, as will be seen by the annexed illustration, has a habit somewhat similar to that of *C. circinalis*; the segments are numerous, contiguous, linear, about 6 in. in length, and $\frac{1}{4}$ in. in width, sharp pointed, slightly narrowed and decurrent at the base. It is a native of New South Wales, and has been shown in good condition by Mr. B. S. Williams, Holloway.

THE FRUIT GARDEN.

EARLIEST AND BEST PEACHES FOR FORCING.

Most of us have at some time or other been puzzled to know the reason why Peach-buds drop; or, if they do not drop, why the fruits fail to set; or if they set, how it is they fail to go through the stoning process: all the usual preventives of such mishaps have been applied, and yet failure occurs no one knows how. I have my own opinion as to the cause of such disasters, but at present I only intend to say that certain kinds are more liable to such ills than others, and to name those which in my experience have proved the most trustworthy for forcing purposes. The three requisites particularly desirable in varieties of Peaches used for early forcing are—first, earliness; secondly, a good, hardy constitution, and a free-bearing habit; and thirdly, quality. In the first place, it may be observed that we are greatly indebted to Mr. Rivers, of Sawbridgeworth, who has, by hybridization, given us several varieties, which not only are certain fruiterers, but which are very early and, with but one or two exceptions, of fine quality. The first of these is Early Louise, a brightly-coloured, handsomely-shaped Peach of moderate size, and one which, with us, has never failed to fruit freely; its only fault is the tenderness of the skin, which makes it a bad Peach for packing. This variety and Early Beatrice are the two earliest kinds known, but of the two Early Louise is by far the best. Early Rivers is another good kind, which ripens a week or ten days after the above, and is, if anything, more delicious in flavour; it has, however, one fault, and that is, its stones are liable to split, which causes the fruit to ripen prematurely; such splitting, however, does not take place to any great extent, unless the tree is excessively cropped, which should therefore be avoided. Large Early Miguonne is another good forcer, and though not nearly so early as the above, it makes a good kind for succession, and is of large size, and extra good in quality. Early Grosse Miguonne must have the next place, it being one of the best midseason Peaches, and next comes Crisnon Galande, a trifle earlier than the preceding, but smaller in size. Dr. Hogg, Alexandra Noblesse, Magdala, and several others have all proved good forciers, but the above are the cream of our trials for early and second early houses.

W. W. H.

STOPPING AND TRAINING VINES.

So long as the Vine has room to grow and develop sufficient foliage to sustain vigour and fruitfulness, it matters very little indeed whether the shoots be stopped one or more joints beyond the fruit. I have tried all ways—sometimes stopping the shoot close to the bud itself; but I never could see that there was the slightest difference in the swelling and ripening of the berries. It is essential, however, that every shoot be well furnished with as many leaves as can well be exposed to the light and air, and anything more than this is injurious. The first-formed or oldest leaves are always the best, and every effort should be made to keep them green and healthy till the fruit is quite ripe, after which they will take care of themselves, the temperature being generally lowered after that date. With these objects in view the Vine grower must, of course, be early on the alert in thinning out the shoots and stopping them, so as to drive the strength of the Vines into the shoots which are to remain. First of all he should thin out the shoots to 9 in. or 18 in. apart on each side of the rods, according to their vigour; next, he should stop them one joint or two beyond the fruit, or five or six joints from their base; and afterwards he should keep them stopped till the end of the growing season, by periodical pinchings. It is the growth and maturing of the leaves that sustain the vigour of the Vines, and do most towards perfecting the fruit and providing for future crops, and a just appreciation of this fact is of the utmost importance to any one who has the charge of them. If Vines be in a tolerably vigorous condition, they will of course go on producing foliage, even should they lose their first leaves by insect attacks or otherwise; but the later-produced leaves cannot altogether compensate for the loss of the former. In tying in the shoots, they should not be bent backwards or downwards to the wires, but trained slantingly upwards, for the sake of giving them greater freedom. Good foliage once produced, the next thing is to preserve them in a healthy condition, to accomplish which it is only necessary to prevent scorching and keep down insects. Scorching will not occur from any cause if a little air be always admitted back and front, and increased, as the weather may necessitate, during the day; and insects—that is, red spider and thrips—will be checked also by healthy treatment more than anything else, because they never make much headway on good, strong foliage; but if they do gain a footing, they must be destroyed or dislodged by the syringe and the application of insecticides. The root culture of the Vine during the summer is

very simple, and consists in mulching the border with slight rotten manure to prevent drought—the surest cause of spider—and supplying copious waterings if there be the least reason to suspect that the roots are dry. If the Vines be well drained, gardeners have seldom time to give their Vines too much water; but they often give them too little in dry seasons. Liquid manure may be given freely, as may also guano, soot, stable-yard drainings, in a diluted state, from the time the Vines begin to grow till the fruit commences to colour, or even later.

J. S.

FRUIT TREES IN POTS.

WE have here a society, the object of which is to encourage good kitchen gardening and hardy fruit culture amongst cottagers by means of prizes and the distribution of fruit trees as presents or at wholesale prices, and it is gratifying to observe that already many of the sheltered gable ends of cottages and other walls of which no use whatever was made only a few years ago, are gradually becoming clothed with Pear, Plum, and Cherry trees, and yielding their owners a remunerative return, while the old-fashioned espalier is again becoming as popular as its merits deserve; for, either on the ground of economy of space, or facility for protection, no form of training is more worthy of recommendation; I must confess, however, that from my own experience, and that of many others, I see no prospect of the golden dreams of profit held out by those who advocate fruit tree culture in pots ever being realized. I will readily acknowledge that growing fruit trees in pots is an interesting pastime in the case of amateurs, who, as a rule, buy both their fruit and experience dearly, but cottagers are in a very different position; they look for definite returns for the outlay of their usually hard-earned surplus cash, and to buy trained fruit trees fit for the purpose, and pots and mats, &c., would require stronger imaginative power as regards the El Dorado of fruit culture than most of them at present possess. The culture of fruit trees in pots on the orchard-house system has not made much progress of late, or fulfilled the high expectations formed respecting it a few years ago, and certainly the balance would be all against trees treated in the manner described in THE GARDEN (see p. 391), for the cost of protecting material would in a few years equal that of a glass roof, and to lay trees on their sides exposed to alternate frosty nights and bright sunshine during the day, would certainly prove a trying ordeal, for which the protection of a mat at night would be but slight compensation. I should, from my own observation of Pear crops, consider Mr. Rivers' conclusions of the safety of his crop to be rather hastily formed, for although no visible harm may have ensued at present, it is not until the fruit-room shelves begin to look pretty well furnished, that growers who have to supply large quantities of fruit feel confident of success; and that this will ever be the case from trees grown in pots, is much question. We have no pot trees here except Vines and Figs, but bad as the season has been, I feel confident of a fine crop of Pears on walls and espaliers by the old-fashioned means of protection that have been employed for years.

Henham.

JAMES GROOM.

May Frosts and Fruit.—The frosts from May 3 to May 10 have made sad havoc with the earliest of the fruit crops. The thermometer on the morning of the 1th indicated 10° of frost, and from the 3rd to the 10th it has shown from 5° to 10°, the wind being east by north-east until the 10th, when it changed to the south, and at noon we had thunder accompanied by a heavy fall of hail and rain. Apricots are considerably injured. Several very old Pear trees on east walls, which were in full flower a month ago, and which promised to bear a heavy crop, have suffered greatly. The same fate has befallen several trees in orchards. Two very old White Heart Cherries on a west wall, which were in full flower on April 28 and which had set a large amount of fruit, are now quite black. The earliest Plums are in the same condition. Apples are now fast opening their bloom; in fact, an old pyramid of the Quarrenden had a great many of them expanded before the frost set in, and they suffered very much. Gooseberries and Currants have escaped tolerably well, more especially Red Currants.—J. CLEMENTS.

Canary Islands Bananas.—At p. 393 there is a short notice of the Bananas now offered for sale in London. Will you allow me to supplement your remarks by stating that the finest Bananas are not grown in Madeira but in the Canary Islands, considerably further south. To those who have tasted them in both places there is no comparison between the fruits, those of the Canaries being much larger, fuller, and finer. Unfortunately but few have found their way to this country, owing to communication not being so frequent, but a short time ago some bunches arrived in good condition, and fetched good prices, and I believe efforts are being made to keep the

market supplied with them. But it is difficult to bring them even from Madeira in good condition, as the sea air blackens the skin and arrests the natural progress to maturity. Bananas, it should be remembered, are always cut green and never ripen on the tree, which dies down, or is cut down after the bunch of fruit is removed. They are propagated by means of the suckers which rise round the root of the fruiting plant bearing them.—J. A. S.

TWO USEFUL PEARS.

Vauquelin.—Our trees of this variety, six in number, were obtained in the form of cordons from the late M. Van Houtte's nursery at Ghent; three of them are grown as cordons on a south wall, and the others have been allowed to grow in the shape of bushes, a

Vauquelin Pear.

form for which this variety seems best suited, as those trees fruit with greater regularity than those on the walls. They bear very large, handsomely-shaped Pears, which are bright straw-coloured when fully ripe, with a tinge of suffused red on the side next the sun. Though not first-rate in flavour, this variety is in that respect superior to many much more generally grown, and it has the advantage of many others which ripen at the same period, viz., beginning of November, of remaining in good condition for a long time after being fully ripe.

Beurre Bachelier.—This is one of the very finest of the many good kinds of Pears. I class it with Marie Louise, Doyenné du

Beurre Bachelier Pear.

Comice, Beurre Hardy, and Winter Nelis, as being equal in flavour to any of them. It is very large, and in outline and shape may be described as a large Thompson's, and it is a good sort to succeed that fine variety, as it ripens about a month later, its season being from the end of November to the middle of December. It is a sure and prolific bearer, and, like the preceding, does best grown in the form of a bush or pyramid.—W. WILDSMITH, *Heckfield*.

COVERING EARLY VINE BORDERS.

I FEAR that, however long Mr. Simpson and I may discuss this subject, we shall never agree. He says his views in reference to the matter are based on experience; mine, though at variance with his, also rest on the same ground. At one time I was a strenuous advocate for heat applied to the roots of all plants, the leaves and branches of which were under a like influence; but subsequent experience has convinced me that in respect to early Vines it was unnecessary. Mr. Simpson admits that he is perfectly well aware that Grapes can be grown, even though the conditions he names be not strictly conformed to. The subject admits of no qualification, no half-measures. He advocates the use of fermenting material, I advocate simple protection; and I have thoroughly satisfied myself that as good early Grapes can be grown without the use of fermenting material as with it, not for a single season alone, but for a continuance; and totally independent of my own experience I have continually confirmatory evidence in the practice of others. Within two miles from where I write are a couple of large Vineries in which the fruit is ripe the middle of this month, and they are forced yearly to come in at the same time; they have some inside border, but from the condition it is in there evidently cannot be many roots in it; they have, however, plenty of room outside, yet on this outside border, neither on this nor on any previous season, has there been anything used, not so much as a particle of non-heat-conducting material. On a season like the present, after such an exceptionally wet autumn and winter, with the ground consequently colder than usual, if fermenting material were ever necessary, it has been during this winter, and yet I very much doubt if, for size of both bunch and berry, perfection in colour and bloom and weight of crop, there are two houses in the kingdom that surpass them, and this is their yearly condition under the same treatment. The Grapes are grown for Covent Garden market, where there is none that excel them, and few that equal them. This is only a solitary instance amongst many that I could quote in favour of my opinion. If Mr. Simpson require stronger evidence than such as this, I do not know how he is to get it. His memory serves him imperfectly when he states that I did not publish my views on the subject when there was so much discussion about it. I presume he alludes to the early part of the winter, unconscious of the fact that it was an article which I wrote in a contemporary in reference to something advanced previously on the subject that was mainly instrumental in starting the question. My reason for not taking further part in it was simply that a severe illness prevented the possibility of my doing so—even so far as to make clear what I had advanced—inasmuch as some were under the impression that in the details which I gave of my experience in the use of fermenting material on Vine borders, it had heated to excess—which was not the case. As to the long and exhaustive experiments which I have made in reference to the use of bottom-heat to plants which are usually subjected to it, I can assure your correspondent that it has been through no disposition on my part to keep anything relating to gardening matters secret, that I have not given them fully. The subject is a highly important one, and to make myself fully understood, it is necessary to treat it to an extent that continual press of other matters has never yet given me time to do.

T. BAINES.

Peach Setting.—Success as regards setting Peaches depends upon having an abundance of fibry roots in a firm, porous, and healthy, well-drained soil, thoroughly ripened wood, and a healthy atmosphere maintained the whole time during which forcing is going on, by judicious ventilation and an even temperature, making use of fire-heat only as a necessary evil. Under such conditions I never experienced any difficulty in securing an abundant "set" in January or even at any other period. In order to encounter every difficulty one has only to allow the roots to occupy a cold, undrained, unhealthy soil, which may have been poisoned by overdoes of manure, either solid or liquid. The wood under such circumstances is sure to be unripe and full of pith, conditions which favour bud-dropping whenever the sap is in full motion. Peach and Nectarine trees should only be permitted to bear a light crop the season after planting, gradually increasing the quantity each year till the trees are fully established. I have planted trees in July, and gathered good fruit from them the following June, and for nine years afterwards they bore excellent crops, and were then in full vigour. Last season I was about to plant a number of Peach trees in two houses in April, but the structures were not ready to receive them. They were firmly potted in large pots, and placed outside against a low wall, to be out of the way of the builders. In August they were turned out of their pots and planted permanently. The soil was rammed firmly round the roots, the points of which were laid out in the fresh soil, a soaking of water was given, and growth continued for a month or more, when

the shoots became brown and hard. The foliage was strong and healthy. About the new year the trees, which had been pruned in October, were allowed to have the ventilators closed at night, and in February early closing, with sun-heat, was practised, but there being no frost no fire-heat was given. The flower-buds were regularly thinned, and all left set, and the whole of the shoots were loaded with fruit, which is now thinned to 12 in. apart, and we expect (judging from the foliage) some fine fruit at the end of June.—M. T.

The Morello Cherry.—Whatever may be the effects of the recent frosts upon the sweet Cherry crop, it is apparent that standard Morello Cherry trees will be heavily loaded. This Cherry seems to be less affected by frost than other kinds, and its comparative immunity in this respect doubtless arises from the pendent or drooping character of its branches. As a standard it is singularly handsome, and on that account deserves a higher place than is commonly assigned to it amongst decorative trees. But beautiful and floriferous as it is in spring, it is even more ornamental during summer when laden with its rich, red crop of fruit; the latter, owing to its tartness, is not so much sought for by birds as that of the sweet kinds. Morello Cherries generally realize good prices in the market, where they are usually sold in baskets containing a dozen pounds.—A. D.

May and Late Duke Cherries.—These two useful Cherries should have a place in every garden; for, by having trees of each variety on walls or the warmest and coolest aspects, a succession of excellent dessert fruit may be obtained as long as Cherries can be said to be in season. These kinds, too, have another advantage, and that is, they require scarcely any pruning in order to induce fruitfulness, as they form naturally fruit-buds and spurs on the current year's wood, and with a little pinching in summer, the winter pruning may be almost entirely dispensed with. As a succession to the supply from walls, these varieties are extremely useful trained as dwarf bush trees, and if well pinched in they may be grown as close together as Currant bushes and be quite as fruitful. Grown in this way they can be readily protected from spring frosts or the attacks of birds by means of fish nets, which should be securely fixed before the fruit changes colour. The Late Duke is exceptionally late in flowering; some trees of it on a north wall are only just expanding their bloom, while Morellos and other late varieties are in full flower. The black fly is a great drawback to successful Cherry culture; therefore, as soon as it is observed, the points should be dipped in Tobacco water, and in a short time afterwards the whole tree should be well washed with the garden engine. When grown as a wall tree the fan system of training Cherries is decidedly the best.—JAMES GROOM, *Henham*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Black Ants and Peach Blossoms.—If these pests had attacked "W. W.'s" Peach blossoms (see p. 352) with the same energy which I have seen them exercise on several occasions, I question whether he would have found the "saucer-of-water ears" effectual or easy of application. As regards the fertilizing of Peach and other fruit blossoms in houses from which bees are excluded, I should place more confidence in a camel-hair brush than on any number of ants. Some, like "W. W.," credit them with the destruction of insect pests, but I am of opinion that they are active agents in conveying them from one plant to another.—JAMES GROOM, *Henham*.

Fig Trees in the Midlands.—The Rev. Canon Angles, Barnack Rectory, has a Fig tree which occupies one side of a south roof. For twenty years past it has never been either pruned or nailed, and the crops which it bears yearly are simply enormous. Another reverend gentleman in this quarter (Stamford) has one of the same variety that overtops the wall from 5 ft. to 6 ft., and which I have repeatedly seen laden. Fig trees under the rule-of-thumb system of culture certainly bear fruit, but not with such freedom as the naturally grown trees. Three years ago I felt determined to try a similar plan, and am thankful to say with the best results. This season the promise is so good that I have treated the young shoots with a tie to the wall and main stems.—R. GILBERT, in "Gardeners' Chronicle."

A Large Orange.—An Orange grown by Mrs. Brewster, of Paradise Valley, California, while growing had to be suspended in a net bag in which it is yet shown. The two circumferences cutting each other at right angles, measure respectively 24 in. and 23 in., while the weight is 4 lbs. A Californian paper in noticing this fruit says:—"This Orange is considerably larger than the Pumulo Orange grown at Riverside recently carried to San Francisco by Mr. Caldwell. The latter weighed 3½ lbs., and its two circumferences measured 24 in. and 22 in." [The fruit here mentioned is probably the Pommefoe now often seen in our markets, and which is more delicate in flavour than the orange.]

New Early Peaches.—As many are anxious to know how the early Alexander Peach is succeeding in various sections, we ("Gardeners' Monthly") append the following, taken from letters handed to us:—Mr. Chas. Downing says:—"The Asnden's June, Honeywell, and Alexander, were all worked on the same tree, and though we could see by the leaves they are distinct kinds, ripened together, and if the fruits were all placed on a dish, no one could select one from the other. Early Beatrice is too small. These are the best early Peaches of fair size." Dr. Watt, of Niagara, Ontario, reports that in that high northern region the Alexander ripened on August 8. Mr. W. P. Robinson, of Atlanta, Georgia, went to Palmetto, fifty miles, to see it in fruit and does not regret the journey.

PLATE LXXVI.

RHODODENDRON AUCKLANDI HYBRIDUM.

Drawn by MRS. DUFFIELD.

THIS beautiful hardy variety of Rhododendron is one of a batch of seedlings raised from R. Aucklandi crossed with the best hardy varieties. R. Aucklandi flowered in the Lawson Nurseries about ten years ago, when the attempt was made to raise a hardy, fragrant race with the blood of this large, fragrant Indian species. The variety we figure partakes of the size and the delicate perfume of the parent, with the hardiness and the bright colouring of the better-known hardy kinds. Seven years ago the batch of seedlings referred to were planted out in an exposed situation to test their hardiness. The majority proved to be insufficiently hardy for open-air culture, but the particular variety now figured and a few others have withstood all the severe winters since without ever showing an injured leaf. It flowered in the spring of 1876 for the first time, a bush about 2 ft. through being covered with bloom. The beauty of the flower is of that delicately toned kind of which colour printing can but give an imperfect idea. We may, however, say from having seen the plant, that its beauty is of a very unusual character, and unique among Rhododendrons. It will form a valuable addition to hardy varieties, and also prove welcome as a conservatory plant. The plant is now being propagated in the Lawson Nurseries, but will not be obtainable in commerce until sufficient stock is ready.

INDIAN FORESTS.

At the last meeting of the Indian section held in the lecture hall of the Society of Arts, an interesting lecture was delivered by Mr. W. Taylor (late Commissioner of Patna) on the Primeval Forests of India. He said that although there were many tracts of country—as, for example, Scinde, part of the Punjab, and elsewhere in Central India—which were almost rainless, and with very little vegetation, yet on the slopes of the Himalyas and other mountain ranges, on the detached ridges in Central India, in the Deccan, and along the Eastern and Western Ghats, there were grand primeval forests, many parts of which probably no human foot had trod—great sources of wealth lying as yet undeveloped. Still, part of them had within the last 20 or 30 years come under the consideration of the Government, which had at last recognized their value, not only for timber for house and ship building, for railway sleepers, and for many other purposes, but also for their general and essential importance to mankind. The benefits of forests were great, and of more than one character. First might be mentioned their direct value as timber for fuel, for their fruits and products, such as india-rubber, dyes, and other productions. They also provided grateful shade to the people. The forests naturally were principally near the mountain slopes down which rapid torrents flowed, irrigating the plains and swelling the great rivers which rolled from north to south; and if it were not for the trees clothing the sides of the hills those waters would rush down in devastating torrents, tearing down bridges, overthrowing buildings, and carrying everything before them. The presence, then, of trees and vegetation on the hill-sides had the beneficial effect of impeding the downward rush of the streams, as well as of moderating and regulating the supply of water to the plains. He could give no better illustration of the relative influence of moisture upon vegetation than the district of the Terai—a tract of land from 15 miles to 30 miles in breadth, lying along the lower ranges of the Himalayan chain of mountains. Beyond that lay another district of about the same breadth, called in the native dialect the Bahadar. That, in fact, was one great filter-bed of sand and vegetation, through which the descending water slowly permeated. The water passed down through the earth until intercepted by a bed of clay and then re-appeared on the surface in the form of springs and wells—a general diffusion of the subsoil moisture. That belt of land, the Terai, was covered with magnificent forests, and it would at once be seen how much they must influence the surrounding country by their effect upon the supply of water to the streams and to the country generally. It was a great pity that Bengal had not been planted with trees, as had been successfully done in the Neilgherries, as well as towards Darjeeling and in many other places. The vast forests of India, great sources of national wealth, were all but unknown as regarded their value, and until recently were uncared for. In the year 1846 the Government of Bombay first deputed Dr. Gibson to assume some sort of supervision and care over these forests, with the view of providing wood for the

dockyards. The supervision then extended to Madras, and from Dr. Gibson passes on to General Cotton and Colonel Michael. With them was afterwards associated Dr. Klegboru, and now, happily, the whole forest system of India was more or less under supervision. A large tract of forest country had been demarked and laid out, and some 6,000,000 or 7,000,000 acres of forest had been brought under the supervision and care of the forest department. But there were still endless tracts of forest which were untouched and lay beyond the supervision which the civil engineers could give to them. The Onde forests were no longer to be left undeveloped, and in time the whole country would be, he hoped, so thoroughly explored that an immense increase would result to the commerce of Great Britain. A vote of thanks to the lecturer closed the proceedings.

The Fuchsia as a Climber.—Though formerly much employed as a conservatory climber, the Fuchsia is now seldom seen grown in that way. Few plants, however, are better suited for the

THE KITCHEN GARDEN.

ASPARAGUS CULTURE.

Of all vegetables none are held in more universal esteem than Asparagus, and yet its cultivation is but little understood, or it would not be the scarce commodity it is in our markets, where its price is so great as to preclude its use except by those in the most affluent circumstances. Considering its hardy nature, the great ease with which it may be grown, and the permanent character of the beds when properly made and cared for, this certainly ought not to be the case, nor is it so elsewhere, as in France and other countries, when in season, a good dish of fine large heads is generally placed upon the dinner-table.

Panax laciniatus.

purpose, inasmuch as they may be had in bloom under good management all the year round. In a small lean-to house at Cliveden, there is a very large Fuchsia which is attractive at all seasons of the year; it is planted at the back of the house, and trained down close under the roof. On the same stock have been grafted from time to time many different varieties, some of which are nearly always in flower, and the blossoms being of different colours, the effect produced is most interesting.—S.

Panax laciniatus.—This graceful fine-foliaged Araliad will form a valuable addition to plants suitable for table decoration; it is of medium growth, and when about 12 in. or 18 in. in height its appearance is strikingly beautiful. The stem is smooth and slender, slightly mottled with brown, the leaves are alternate, and the leaflets deeply cut or lacinated, and of a light and pleasing shade of green. It is a native of the South Sea Islands, and when shown by Mr. B. S. Williams, Holloway, at one of the meetings of the Royal Horticultural Society, it was awarded a first-class certificate.

Preparation and Treatment of the Beds.

The time of year having now arrived for renovating old beds and reforming new ones, many readers of THE GARDEN may be glad to know how they can best improve the growth of what they have or make such plantations as will afford them an abundant supply for the future. As regards old beds little can be done to add either to the quantity or quality of the produce for this season, as the crowns that are now producing heads for cutting were formed during last summer and autumn; and if these be small and weak, the whole should be left to grow instead of cutting them for use. This will so add to the strength of the plants by stimulating root-action as to recruit their exhausted energies; and to aid them in this a good dressing of thoroughly decomposed manure should be scattered over the beds and alleys as a mulching. Besides enriching the soil by the constant washing it must necessarily undergo during rainfall, it

will act as a conservator of moisture by intercepting evaporation, which has a very important bearing on the successful cultivation of Asparagus, for, being a native of our sea-shores, it cannot bear its roots in dry, sun-parched ground while making its growth. This being the case beds should not be without a top-dressing of some kind during the summer, and if in addition a soaking of liquid manure can be given once or twice during July and August, the plants will be greatly benefited. Salt applied now forms an excellent fertilizer and is highly beneficial in a variety of ways, as it keeps down weeds, destroys slugs, and helps to keep the soil in a uniform state as to moisture, in addition to which it imparts an improved flavour to the heads when cooked if applied just before cutting. My favourite mixture at this season for surfacing the soil in which Asparagus is grown, is about equal quantities of soot and salt, to which a little guano or superphosphate has been added, but the two latter must be used with a sparing hand, as 4 lb. or 5 lb. is sufficient for a good-sized bed. By annually using the above at this season, in addition to the autumn-dressing of manure, and not continuing the cutting after the first week in June, all exhausted beds may be rejuvenated, as there is scarcely any limit to the age of Asparagus plants. The practice of digging out the alleys is most barbarous, and cannot be too strongly condemned, as it severs many of the most active and important roots, and forms ditch-like channels for the retention of water during the winter, and serves no useful purpose whatever. Why such a practice ever came into vogue is a mystery, and why it should still be continued is still more inexplicable, but when once a particular custom is adopted it is a difficult matter to persuade people of its inutility, so tenaciously do many cling to old usages. The idea appears to have been that it was necessary to protect it from frost, but that is a most fallacious notion, for the Asparagus plant in its dormant state is as hardy as a Dock, and, if it were not, it could not endure the treatment to which it is annually subjected. I question if there be any other plant that would undergo the process of burial 12 in. or 18 in. deep during six of the wettest and dullest months of the year without showing unmistakable signs of suffering; and that Asparagus does manage to survive and struggle on, only shows how tenaciously it clings to life, and what a long-suffering subject it is. If, instead of digging out the alleys between the beds, and packing the soil so removed on the top of them, a good heavy dressing of pig or cow manure were scattered over the whole surface, and allowed to remain during the winter, the rich juices would be carried down, and the manure would become so sweetened and pulverized as to moulder away by the time the rich succulent heads of Asparagus make their appearance in the spring. It should be remarked that so long as Asparagus is in use, the whole of the heads, both small and great, should be cut, and not the strong only as is often the case, as then only the weak shoots left continue to grow, while many buds remain dormant for a time, and eventually die away altogether. As before observed, the cutting should not be too prolonged, as that weakens the plants; and when once it ceases, every encouragement should be given by keeping the beds perfectly free from weeds to get the stems as stout and robust as possible. In exposed situations these are apt to get blown about, and to prevent this it is a good plan to stick a few brushy Pea-sticks in the beds for their support, for should they get broken or damaged, the plants will be considerably weakened. The French, who are by far the best growers of Asparagus, pay as much regard to preserve the tops from injury as florists to their Dahlias or Hollyhocks, and the result of their careful attention may be seen in the enormous size of the heads.

Choice of Soil for New Beds.

As regards the formation of new beds, the principal thing is to make choice of a good piece of ground of great depth with, if possible, a naturally dry bottom, such as a subsoil of sandy gravel will afford, and this secured, the next step is to trench and prepare it for the reception of the plants. As the beds should last a lifetime, no pains should be spared in their construction, especially as success depends more on the way in which they are prepared than on any subsequent atten-

tion. Manure must be applied with a liberal hand; indeed, it is almost impossible to use too much of it for Asparagus growing, but although this is the case, it should not be in that crude, rank state that it is when fresh from the farmyard, for if buried in such an undecomposed condition, it lies inert in the soil, and is a long time before it is at all suitable as nutriment for the roots. In trenching the ground, a good wide opening should be made, not less than 3 ft. across, and, if the land will bear it, nearly or quite the same depth, so as to leave plenty of room to work in the manure, and to break up the soil in such a manner that the roots can ramify freely in search of moisture and food. In strong, heavy land Asparagus is apt to go off in the winter from excess of moisture, and, therefore, where such is the character of the soil, rotten leaf-mould, sharp river-sand, or road-scrapings should be added to the manure and worked in with it during the operation of trenching, so as to incorporate the mass well together.

Marking out and Planting.

The next process is to mark out the beds, the usual and most convenient width of which is 5 ft., with 2-ft. alleys between, a distance that allows ample space for all purposes. In planting the proper way is to strain a line down the centre of the bed, and with a sharp spade to cut a trench 9 in. or 12 in. deep in which to place the roots. Plants of a year old are the most preferable, and may be put in any time from now to the middle of June or even later with the greatest success, provided a dull, showery time is chosen for the work, and the soil is well washed in amongst their fibres before finally covering them up. The two outer rows should be 15 in. from the centre, and the plants about 12 in. apart in each. This allows more room than is generally given, but if fine heads be desired they cannot be had by overcrowding. Formerly Asparagus used to be planted just as it was beginning to move, but I have always seen it thrive better when it had made some top growth, as then the roots are actively at work and quickly recover from any injury they may have received; whereas earlier in the season the injured parts rot, either from the excessive quantity of moisture they contain in themselves or what they take up from the soil. One disadvantage in late planting is that the plants must be grown on the spot, as they do not travel well from a distance when in the forward state they now are unless their transit is unusually quick.

Sowing the Seed.

Some of the best beds I have were obtained from sowing the seed instead of planting, and I can strongly recommend the adoption of the plan by others as a safe and certain way of getting Asparagus established with very little trouble. The ground should be prepared precisely the same as if it were to be planted, and two or three seeds inserted in rows at 12 in. or 15 in. apart, and when up thinned out and left singly, after which the growth will be most rapid, and, at the end of the second or third year, little if at all inferior to any that may have been transplanted. As neither these nor one-year old plants will occupy all the ground the first season, the vacant spaces between may be made use of to grow some light summer crop, such as Lettuces, Radishes, or even Cauliflower if planted in the alleys between; but whatever is grown must not in any way be allowed to interfere or encroach on the Asparagus to rob it of its nourishment or draw it up weakly. The subsequent treatment of these young plantations should be in all respects the same as for the old established beds. Those who have not the time or the spare ground to start with fresh beds at once may still sow a row of seed in some rich, open part of the garden, so as to be prepared with fine strong plants for next season. The best and largest kind to grow is Conover's Colossal, an American variety introduced some years since, and although with me it does not attain the gigantic proportions it is said to do in that country, it is superior to ours.

S. J.

Late-planted Potatoes.—Mr. Gilbert's system and time of planting are in accordance with the practice of a large number of growers who make the cultivation of Potatoes a speciality. I have always observed that Potatoes planted in April grew more freely, were ready for use as early, and were in every other respect equal to

those planted in March; they generally escaped many of the calamities caused by early planting. These remarks do not of course apply to warm, well-prepared borders, on which protection is used. Last season most of our Potatoes were planted in the third week of May, and so far as the early kinds were concerned (Kidneys especially) we never had a finer crop, both as regards quantity and quality. Late kinds, however, planted at that time seemed to suffer worse than usual from disease, and their quality was, on the whole, inferior to that of the early varieties; planting thus late was not from choice but necessity. The ground being new was hard and dry through drought, and could not be got ready earlier. This season, too, we are placed somewhat similarly, for we have still (May 21) a quantity of Potatoes to plant; they are at present in a cool shed, spread out thinly, and have only sprouted about $\frac{1}{2}$ in. One of the evils from which Potatoes suffer severely is their being kept in a close structure with a temperature high enough to cause early sprouting. Thus treated, when placed in the cold ground, their vigour is either destroyed or impaired. When Potatoes are forced very gently with plenty of air they do much better in every respect than when grown in a temperature above 45° or 50°. Our pot Potatoes, which were ready in March, were grown in a cool Peach-house, with air on almost every day and night throughout the winter, and they were about the best we ever had so early in the season; they were sprouted in the first place in warmth, then well hardened off before being potted.—M. T.

GARDEN MANURES.

EVERY intelligent farmer is fully alive to the importance of keeping up the fertility of his land by frequent and liberal supplies of manure, and gardeners are certainly not behind in this all-important matter. It very often happens, however, that the gardener is placed at a disadvantage as regards obtaining an adequate quantity. As a rule, the garden is a secondary consideration compared with the farm as respects the raising of crops requiring manure. This is not as it should be, for gardens are generally so heavily and constantly cropped that it is impossible to keep up their fertility without heavy supplies of nutriment for the soil. Where vegetables are required in quantity the ground is usually cropped twice, and part of it three times during the year, and garden produce of every kind is very exhaustive to the soil. Even flower-beds, especially those that are required to yield two crops of flowers in the year, require plenty of decomposed manure or its equivalent. There are three things necessary for the proper cultivation of a garden, viz., trenching, manuring, and the rotation of crops. I have just stated that garden crops are very exhausting to the soil; to counteract this a clear perception of all the requisite conditions for continued fertility is necessary on the part of the cultivator. Science has come to the aid of experience to prove the importance of the three conditions here named. It is quite possible that a garden might be regularly manured and a proper rotation of crops observed, and yet the garden lose its fertility. All plants are composed of organic and inorganic constituents; these are derived chiefly, if not exclusively, from the soil through the medium of the roots. At present it is not my object to inquire what share the leaf has in feeding the plant; for, whether a plant derives any of its sustenance from the air through the medium of the leaf or not, it is agreed on all hands that it is nourished chiefly through its roots. A plant, in short, absorbs the nutritive qualities of the material in which it is planted; it carries away organic and inorganic material from both soil and manure. This being so, these materials must be restored to the land. Johnson tells us that 1000 lb. of the ash of Potatoes consist of the following ingredients:—Potash, 557; soda, 19; lime, 20; magnesia, 53; oxide of iron, 5; phosphoric acid, 126; sulphuric acid, 136; silica, 42; and chlorine, 42. This is the proportion in which a crop of Potatoes takes these inorganic constituents from the soil. But the same authority tells us that the same weight of Turnip ash is in very different proportions, viz.:—Potash, 419; soda, 51; lime, 136; magnesia, 53; oxide of iron, 13; phosphoric acid, 76; sulphuric acid, 76; silica, 79; chlorine, 36. The necessity will thus be seen at a glance from the analysis of these two ordinary garden vegetables, of restoring to the soil what has been abstracted from it, and also of a change of crops. The ashes of the Potatoes contain only 20 lb. of lime, while the same quantity of the Turnip ashes contain 136 lb., or nearly seven times as much. If a crop of Turnips were grown continuously on the same plot of ground, they would certainly degenerate, simply from want of a sufficiency of lime, as well as other materials requisite for its full development. Hence the importance of manure and a proper rotation of crops; but experience has proved that old gardens, the crops of which have been regularly changed and manured from time to time, fail to produce Turnips as well as other crops. What is the reason of this? A

change of crop does not restore fertility to the soil; nor does manure of whatever kind, or in whatever quantity applied, restore all the constituents that have been absorbed by successive crops. Trenching or subsoiling must be resorted to, in order to supply the mineral matters abstracted from the surface-soil by years of hard cropping. A rotation of crops simply means that a Turnip or a Cabbage will carry away what a Potato has left; but such rotation will go on exhausting the soil more and more; nor is manure alone able, as I have already said, to prevent this exhaustion, for the simple reason that the component parts of manure do not contain all the required nutriment for the soil that plants carry away. I would therefore impress on those who have the care of old gardens that they must trench, manure, and adopt a proper rotation of crops. Many of our ancestors were most excellent and successful cultivators; they could grow fruit and vegetables to perfection; they knew little, perhaps nothing, about chemistry; but modern chemistry has only confirmed the practice of the leading cultivators of previous generations, whose motto was—deep cultivation, thorough manuring, rotation of crops, and clean tillage. E. R. Q. P.

VEGETABLE MARROWS.

THE general use of these as a choice vegetable for all classes within the last few years marks one of those changes of public taste which are slow in their growth and exceedingly rare. Man is emphatically conservative in the matter of his food. Hence every new vegetable has to wait long and patiently before being accepted and used in a general way as an article of diet. Vegetable Marrows should be eaten young—say when about one-fourth or one-sixth their natural size. Cut in this state, and boiled quickly until quite tender in plenty of water, carefully strained, and served with melted butter, they are second to no vegetable that comes to table, not even excepting green Peas or Asparagus. Early cutting, careful cooking, and serving are the chief points to which attention should be paid; but there are others, one of the principal being rapid growth. Grow Vegetable Marrows quickly, and they are almost sure to be good; grow them slowly, and you will find them often tough and bitter. Hence the soil or place in which they are grown can hardly be too rich for them. Not but what they do fairly well in any good garden soil, but the richer it is the better. On a rubbish-heap, for instance, Vegetable Marrows grow with wonderful vigour, and fruit abundantly. It is also a capital plant for filling any space, nook, or corner, covering dead fences or walls, scrambling over outbuildings, or growing in any out-of-the-way or rubbishy place. Vegetable Marrows should be sown in April under glass. A temperature of 55° or 60° will soon cause their seeds to vegetate. As soon as the plants form a rough leaf pot them off singly in 6-in. pots, and return them to a frame until re-established. The plants may then be gradually inured to the open air, and finally planted out in their fruiting places about the end of May. It is of no use putting them out earlier, as they are tender and easily injured by frost. When they make a good start in their new quarters the shoots may be stopped to make each throw out from six to eight leading shoots or stems. These may be led off in different directions to form the plant, and it is seldom that any more stopping or attention will be necessary. After the plants reach a considerable size or age a Marrow will be produced under each leaf, and if the fruits be cut young and none be left to ripen seeds, the plants will go on bearing until arrested by frost in October. If planted on rich mounds or manure heaps the plants will need no water; but if on poor, thin, or sandy soil, they should be plentifully watered with manure or clean water, and must not on any account be allowed to flag, else mildew will follow on the heels of the check, and the plants and produce alike be destroyed. A yet simpler way for those who have no glass and are content to wait a little longer for their Marrows, is to plant the seeds in the ground at once—about the beginning of May. A hand-light, or bell-glass, or pot placed over them may bring them up all the sooner: but they will come up without any such aids to germination and make good progress, and the plants will yield a good crop throughout the late summer and autumnal months. As regards varieties, there is the New and Improved Custard, which is much liked by some; others consider it too rich and marrow-like to be pleasant eating. The flavour is distinct and peculiar, and it needs but little imagination to suggest the flavour of custards. Moore's Vegetable Cream has a rich, mild, sweet flavour, as the name suggests. But there are few or no Vegetable Marrows really superior to the old white and green striped, if these be grown rapidly and gathered young. D. T. FISH.

Tarragon.—Those who find any difficulty in growing this useful herb, should make a compost of road-scrappings, old mortar rubbish, and leaf-mould, and in this it will supply any quantity of produce.—J. GROOM.

GARDENING AND BULB GROWING IN HOLLAND.*

In Holland every man is a boatman more or less; everything begins and ends at the water-side, and where in the formation of a park or garden there does not happen to be already a perplexing superfluity of water, the Dutchman's love of the element leads him to the formation of straight canals and circular puddles. It is a most important feature of gardening and farming everywhere, for manures, soils, seeds, trees—whatever has to be carried to or from the land—is carried in boats or barges, and it is no uncommon thing for a nurseryman wanting trees for a customer, to push a boat into the quarter and draw out the trees with his hands without using pick or spade, or any other implement. A sandy soil full of water will not hold anything tight, unless it be the water, which never goes away. Nevertheless, the hollow polder with its verdant pastures and low level ditches, the great canals that rise above it and produce the curious spectacle of ships sailing in the air, the frequent changes of light and shade as the sunshine struggles through the humid atmosphere, the ever-recurring well-made road, and trees in regular rank and file, afford scenery agreeable to the eye, and immensely interesting to a connoisseur of Dutch pictures, while the cities and villages abound in features that, to English eyes, are at once distinctive, quaint, and picturesque. That the climate—more especially in the north—is characterised by greater cold in winter and greater heat in summer than we are accustomed to is well known. As a rule, glass houses of all kinds, including pits and frames, are furnished with substantial shutters, which can be quickly passed over the lights to convert the structures into dark boxes while severe frosts prevail. Reed mats are everywhere used to protect fruit trees and bulbs when making their spring growth, while the German stove in the bedroom tells the same tale of pinching weather in the dark season of the year. The want of good fuel of necessity exercises an influence on horticultural industries, and hence the amount of glass employed is quite infinitesimal as compared with its use in this country, or even in France and Belgium.

In respect of the style of Dutch gardens, generally speaking it is in every respect the same as the French. Clipped trees and geometrical complications are by no means so common as usually supposed, and it would be scarcely unjust to say that in Holland there are no gardens at all. A fair study of the domestic taste may be made in the little village of Broek, which is essentially Dutch, and in its way famous for typical representation. I noticed here a charming lot of Hollies and other handsome trees in the churchyard, the ground beneath them being golden with the little *Celandine*, and in the rear of Dame Fregere's house is a garden of clipped Hollies of the most fantastic sort, the trees being formed into a kind of round-topped hedge, from the summit of which rise a number of cocks and hens, and chimneys, and candlesticks, obtained by systematic clipping. A Dutch garden usually comprises a patch of turf of indescribable outline, enclosed and intersected by numerous walks, bounded by a series of canals which lead away to ponds and summer-houses, with a parterre of the orthodox geometric fashion, for a display of flowers. The inscriptions on houses, gate-posts, and pavilions are much more calculated to interest the stranger than the contents of the gardens; nevertheless, horticulture in Holland comprises skilful management of fruit trees and vegetables, and a moderate use of trees and ornamental flowers. That the last are not universally in favour may be judged from the fact that in the course of a fortnight's continuous and assiduous exploration I saw but one good display of bulbous flowers wholly unconnected with commercial culture, and that was in the public square in Amsterdam, where stands the statue of Rembrandt, at the foot of which were some brilliant beds of *Hyacinths* and *Tulips*. The most agreeable scenes of a strictly rural kind are at Haarlem, Alkmaar, and the Hague, where we see trees of fine growth unmitigated by saw or knife, with clean stems, containing sound timber, the product of some better soil than the loose sand or greasy peat met with generally on the surface. If you ask how these *Beeches*, *Oaks*, *Limes*, and *Elms* subsist on land that appears by its splendid covering of golden Moss too poor

to produce Grass even, you have but to remember that it is customary to build upon piles, and in driving these down a firm subsoil is met with, and beyond doubt it is the firm subsoil that makes the fine timber we see in a few specially favoured districts. Between Haarlem and the Dunes, and especially towards the ruins of Brederode, the soil is peaty, and trees of all kinds thrive upon it. Hence we see in the home gardens of the wealthy bulb-growers beautiful collections of ornamental trees and shrubs, and occasionally capital fruit gardens, the trees being for the most part trained as upright or oblique cordons. In the *Oak coppices* beyond may be heard all the song birds of Europe—the thrush, blackbird, nightingale, robin, chaffinch, and many that are scarcely known in Britain; in the open fields are seen myriads of rooks and starlings, and the storks are amusingly conspicuous.

In Holland wall trees are usually trained on lattices of wood, and wooden walls are much employed, and everywhere Reed mats are in use for protection, the spring frosts being peculiarly destructive, owing to the prevailing humidity of the climate. There is no parallel in Holland to the Kentish orchard of unpruned trees, there is no such thing known as the Apple tree that produces forty bushels of fruit; but so far as fruit growing obtains attention, it is pursued with artistic skill and patience; and the pruning and pinching are equal to the best work of the kind seen in French and Belgian gardens. In a country where peat runs into sand and sand runs into water, and the north wind is unimpeded, and rages in its own wild way over the land, fruit growing can never become an important industry; and perhaps the artificial treatment of fruit trees that prevails is amply justified by the circumstances.

In the culture of vegetables the Dutch are adepts. Everywhere may be seen Lettuces of remarkably fine quality, also Lamb's Lettuce, Cabbages of a peculiar yellow colour, that are of excellent quality when cooked, and good Broccoli and Cauliflowers. A travelling greengrocer's shop, drawn by a great dog, managed by a buxom woman, whose head is adorned with a broad band of gold, with gold blinkers behind the eyes, and spirals of gold projecting into space, like ram's horns from fairyland, will attract attention, not only by its general equipment, but by the multitude of baskets, for the far-spreading shop or barrow will carry at least a dozen large well-made baskets, all filled with the most tempting green stuff. If the Dutch demand special praise for any special thing in the vegetable way, they shall have a heap of adulations for their culture of the Cabbage Lettuces, for they come to market the size of a cricket ball, and as round and tight, the colour a bright golden green, the texture crisp and tender, the flavour buttery and delicate. All the Salads are well done; but there is room for improvement in respect of *Seakale* and *Asparagus*, and if there be no room for improvement, there is at least excuse for remark on the subject of Potatoes. Those served on good tables are always small, the largest being just the size as may be described by bringing the tips of the thumb and forefinger together to form a circle. These are usually excellent in quality, and the variety most prized is the Dutch Silver Skin. The neat little Potatoes destined for first-class tables are grown on the sand-hills; but in the bulb grounds large Potatoes are grown, and are sent away to the starving English, or find a market amongst the poorer classes in Dutch towns. The sandy soil is prepared for bulb culture by extravagantly manuring it with cow-manure at the rate of a shilling a barrowload (a barrowful being the unit in the commercial view of the subject), and then it is planted with Potatoes. Now for this culture round Potatoes are mostly employed, and the sets consist of large Potatoes newly cut into convenient-sized pieces. Our friends are not expert in exhibiting Potatoes, if we may judge them by a collection of some forty or fifty sorts presented at the Amsterdam exhibition. A sorrier lot of samples we might travel far and wide to see, but happily not many saw them, for they were removed the day after they were staged, and their place supplied by a fine collection of models of various kinds of fruits. It is somewhat singular that in a country where water fights with the land for supremacy, the Water-Cress is a thing almost unknown. We found a few in one of the small canals, and received for explanation that an English family had resided on the spot and had introduced the Cresses.

The bulb farms in the neighbourhood of Haarlem constitute

* Read by Mr. Shirley Hibberd at the Hackney Gardeners' Improvement Society.

a very distinctive feature in the horticulture of Holland, if, indeed, we may consider the business in the category of horticultural, and not of agricultural enterprises. Its extent, the spirited manner in which it is conducted, the respectability, intelligence, and geniality of the men engaged in it, and the social comfort that prevails throughout the district tell with emphasis how a profitable industry raises the standard of a people. To convey any adequate idea of the remarkable displays of colour the country presents when the bulbs are in flower is simply impossible. The utter absence of all art in the disposal of colours, the hard square blocks and sharp oblong strips in which the colours appear, so far from lessening our interest or weakening our surprise, tend rather to augment them both, for we know they are grown for trade purposes solely, and we do not expect either geometrical patterns or studied harmonies of colour. Chance harmonies occur that are wonderful, and if there be discords sometimes apparent, the

like foliage. On taking one out of the ground it is found to contain a vast number of oval bulbs about the size of a finger nail; these by the end of the season ripen into bulbs as large as Filberts. All true bulbs may be caused to form bulbils by judicious mutilation; but corms, such as the Crocus and the Gladiolus, cannot be operated on in this way, and, indeed, they form their progeny on the crown in clusters. Many kinds of Tulips naturally multiply with such rapidity that there is no need for any special operation to expedite the business, and of Crocuses considerable numbers are raised from seed. If it be asked at what age the bulbs begin to flower, the answer must be that with all the sorts it is no uncommon thing to see flowers in beds containing bulbs of the first season; and, indeed, the beds in which hollowed Hyacinths are planted show here and there little spikes carrying three or four flowers, the produce of bulbils that have not yet attained to an independent existence. Therefore, it is a question of no

Terrace and Trees in the Villa d'Este.

general splendour and the overwhelming magnitude of the display render it impossible for the mind to dwell upon trifling details. The floral industry of Haarlem and its suburbs is directed for the most part to the production of Hyacinths, Tulips, Ranunculuses, Anemones, and Narcissus, the two first taking the lead. Crocuses, Snowdrops, and Lilies are not much grown in this district; but the keen eye will detect patches of them in the course of a railway ride. In preparing the land for bulbs immense quantities of cow manure are used, and although the country produces this article in plenty, the great demand for it renders it very expensive. In every case a crop of Potatoes is taken off the newly-prepared ground, and after the Potatoes Hyacinths are planted, and after these Tulips. The routine culture of the bulbs is very simple. The bulbs selected for increase of stock are usually mutilated by cutting incisions in the plate, or the interior is scooped out, the result being that on the edges of the scales that remain vast numbers of little bulbils are formed. The mutilated bulbs are planted without any separation of the scales, and soon throw up tufts of grass.

moment what is the age of a particular bulb; generally speaking they are saleable after the second season, and in fine condition after the third, and as a new variety of Hyacinth can be got up for the market in five years, it is evident that the first start being safely effected the multiplication thereafter is in a geometrical ratio. A variety that now engrosses attention, and is being multiplied to the utmost, is King of the Blues, the best of the blue Hyacinths, and very telling when seen *en masse*. The raising of the seedlings is carried on by the smaller growers, who sell their best novelties to the larger men, the latter rarely giving their attention to such work as the production of new varieties.—“Gardeners’ Magazine.”

Terrace and Trees in Villa d'Este.—The illustration of the above may suggest the question, what would the terrace, &c., be without the trees? about as satisfactory as any other piece of ordinary masonry. In many terraced gardens admittedly beautiful, both here and abroad, may be noticed the same relief of the stone by vegetation; for example, at Clivedon, at Haddon Hall, and Shrubland.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 435).

Mallows.

Antonio.
*Sebastian.*He'd sow it with Nettle seed.
Or Dockes, or Mallows.*Tempest*, act ii., sc. 1.

The Mallow is the common roadside weed (*Malva sylvestris*), which is not altogether useless in medicine, though the Marsh Mallow far surpasses it in this respect. But the common Mallow is a dear favourite with children, who have ever loved to collect, and string, and even eat its "cheeses;" and these cheeses are a delight to others besides children. Dr. Lindley, certainly one of the most scientific of botanists, can scarcely find words to express his admiration of them. "Only compare a vegetable cheese," he says, "with all that is exquisite in marking and beautiful in arrangement in the works of man, and how poor and contemptible do the latter appear. . . . Nor is it alone externally that this inimitable beauty is to be discovered; cut the cheese across, and every slice brings to view cells and partitions, and seeds and embryos, arranged with an unvarying regularity, which would be past belief if we did not know from experience, how far beyond all that the mind can conceive, is the symmetry with which the works of Nature are constructed."

As a garden plant of course the Wild Mallow has no place, though the fine-cut leaves and faint scent of the Musk Mallow (*M. moschata*) might demand a place for it in those parts where it is not wild. But our common Mallow is closely allied to some of the handsomest plants known. The Hollyhock is one very near relation, the beautiful Hibiscus is another, and the very handsome *Fremontia californica* is a third that has only been added to our gardens during the last few years. Nor is it only allied to beauty, for it also claims as a very near relation a plant which to many would be considered the most commercially useful plant in the world, the Cotton-plant.

Mandragora, or Mandrakes.

- (1)
- Cleopatra*
- . Give me to drink Mandragora.

That I may sleep out this great gap of time.
My Antony is away.*Antony and Cleopatra*, act i., sc. 5.

- (2)
- Iago*
- . Not Poppy, nor Mandragora,
-
- Nor all the drowsy syrups of the world
-
- Shall ever medicine thee to that sweet sleep
-
- Which thou own'dst yesterday.

Othello, act iii., sc. 3.

- (3)
- Falstaff*
- . Thou Mandrake.
-
- 2nd Henry IV.*
- , act i., sc. 2.

They call'd him Mandrake.—*Ibid.*, act iii., sc. 2.

- (4)
- Suffolk*
- . Would curses kill as doth the Mandrake's groan.
-
- 2nd Henry VI.*
- , act iii., sc. 2.

- (5)
- Juliet*
- . And shrieks like Mandrakes torn out of the earth
-
- That living mortals hearing them run mad.

Romeo and Juliet, act iv., sc. 3.

There is perhaps no plant on which so many books and treatises (containing for the most part much sad nonsense) have been written as the Mandrake, and there is certainly no plant round which so much superstition has gathered, all of which is more or less silly and foolish, and a great deal that is worse than silly. This no doubt arose from its first mention in connection with Leah and Rachel, and then in the Canticles, which perhaps shows that even in those days some strange qualities were attributed to the plant; but how from that beginning such, and such wide-spread, superstitions could have arisen, it is hard to say. I can scarcely tell these superstitious fables in better words than Gerarde described them. "There hath been many ridiculous tales brought up of this plant, whether of old wives or some ranaque surgeons or physicke-mongers I know not. . . . They adde that it is never or very seldome to be found growing naturally but under a gallowes, where the matter that has fallen from a dead body hath given it the shape of a man, and the matter of a woman the substance of a female plant, with many other such doltish dreams. They fable further and affirme that he who would take up a plant thereof must tie a dog thereunto to pull it up, which will give a great shrooke at the digging up, otherwise, if a

man should do it, he should surely die in a short space after." This, with the addition that the plant is decidedly narcotic, will sufficiently explain all Shakespeare's references to the plant. Gerarde, however, omits to notice one thing which, in justice to our forefathers, should not be omitted. These fables on the Mandrake are by no means English mediæval fables, but they were of foreign extraction, and of very ancient date. Josephus tells the same story as held by the Jews in his time and before his time. Columella even spoke of it as "semi-homo," and Dr. Daubeney has published in his "Roman Husbandry" a most curious drawing from the *Vienua MS.* of Dioscorides in the fifth century, "representing the Goddess of Discovery presenting to Dioscorides the root of this Mandrake (of thoroughly human shape) which she had just pulled up, while the unfortunate dog which had been employed for that purpose is depicted in the agonies of death." All these beliefs have long, I should hope, been extinct among us; yet even now artists who draw the plant are tempted to fancy a resemblance to the human figure, and in the "Flora Græca," where, for the most part, the figures of the plants are most beautifully accurate, the figure of the Mandrake is painfully human.

As a garden plant, the Mandrake is often grown, but more for its curiosity than its beauty; the leaves appear early in the spring, followed very soon by its dull and almost inconspicuous flowers, and then by its Apple-like fruit. This is the Spring Mandrake (*Mandragora vernalis*), but the Autumn Mandrake (*M. autumnalis*) may be grown as an ornamental plant. The leaves appear in the autumn, and are succeeded by a multitude of pale blue flowers about the size of, and very much resembling the *Anemone pulsatilla* (see Sweet's "Flower Garden," vol. vii., No. 325). These remain in flower a long time. In my own garden they have been in flower from the beginning of November till April. I need only add that the plant is a native of the south of Europe and other countries bordering on the Mediterranean, but it was very early introduced into England. It is named in Archbishop Ælfric's Vocabulary in the tenth century with the very expressive name of "Earth-apple;" it is again named in an Anglo-Saxon Vocabulary of the eleventh century (in the British Museum), but without any English equivalent; and Gerarde cultivated both sorts in his garden.

Marigold.

- (1) *Perdita*. The Marigold that goes to bed with the sun,
And with him rises weeping. These are flowers
Of middle summer. *Winter's Tale*, act iv., sc. 3.
- (2) *Marina*. The purple Violets and Marigolds
Shall as a chaplet, hang upon thy grave
While summer days do last. *Pericles*, act iv., sc. 1.
- (3) *Song*. And winking Mary-buds begin
To ope their golden eyes. *Cymbeline*, act ii., sc. 3.
- (4) Great princes' favourites their fair leaves spread
But as the Marigold at the sun's eye. *Sonnets* 23.
- (5) Her eyes like Marigolds had sheathed their light,
And canopied in darkness sweetly lay
Till they might open to adorn the day. *Rape of Lucrece*.

There are at least three plants which claim to be the old Marigold. 1—The Marsh Marigold (*Caltha palustris*). This is a well-known golden flower—

The wild Marsh Marigold shines like fire in swamps and hollows gray.
Tennyson.

And there is this in favour of its being the flower meant, that the name signifies the golden blossom of the marsh or marsh; but, on the other hand, the *Caltha* does not fulfil the conditions of Shakespeare's Marigold—it does not open and close its flowers with the sun. 2—The Corn Marigold (*Chrysanthemum segetum*) is a very handsome but mischievous weed in Cornfields, not very common in England and said not to be a true native, but more common in Scotland, where it is called Goulands. I do not think this is the flower, because there is no proof, as far as I know, that it was called Marigold in Shakespeare's time. 3—The Garden Marigold or Ruddes (*Calendula*

officialis. I have little doubt this is the flower meant; it was always a great favourite in our forefathers' gardens, and it is hard to give any reason why it should not be so in ours. Yet it has been almost completely banished, but may often be found in the gardens of cottages and old farmhouses, where it is still prized for its bright and almost everlasting flowers (looking very like a *Gazania*) and evergreen tuft of leaves, while the careful housewife still picks and carefully stores the petals of the flowers, and uses them in broths and soups, believing them to be of great efficacy, as Gerarde said they were "to strengthen and comfort the heart."

The two properties of the Marigold—that it was always in flower, and that it turned its flowers to the sun and followed his guidance in their opening and shutting—made it a very favourite flower with the poets and emblem writers. T. Forster, in the "Circle of the Seasons," 1828, says that "this plant received the name of *Calendula*, because it was in flower on the calends of nearly every month. It has been called Marigold for a similar reason, being more or less in blow at the times of all the festivals of the Blessed Virgin Mary, the word gold having reference to its golden rays, likened to the rays of light around the head of the Blessed Virgin." This is ingenious, and, as he adds, "thus say the old writers," it is worth quoting, though he does not say what old writer gave this derivation, which I am very sure is not the true one. The old name is simply *goldes*, and Chaucer spoke of them as the "yellow-goldes."

But it was its other quality of opening or shutting its flowers at the sun's bidding that made the Marigold such a favourite with the old writers, especially those who wrote on religious emblems. It was to them the emblem of constancy in affection, and sympathy in joy and sorrow, though it was also the emblem of the fawning courtier, who can only shine when everything is bright. As the emblem of constancy, it was to the old writers what the Sunflower was to Moore—

The Sunflower turns on her god when he sets
The same look which she did when he rose.

It was the Heliotrope or Solsequium or Turnesol of our forefathers, and is the flower often alluded to under that name. "All yellow flowers," says S. Francis de Sales, "and above all those that the Greeks call Heliotrope and we call Sunflower, not only rejoice at the sight of the sun, but follow with loving fidelity the attraction of its rays, gazing at the sun, and turning towards it from its rising to its setting" ("Divine Love"—Mullholland's Translation).

Of this higher and more religious use of the emblematic flower there are frequent examples. I will only give one from G. Withers, a cotemporary of Shakespeare's later life—

When with a serious musing I behold
The grateful and obsequious Marigold,
How duly every morning she displays
Her open breast when Phoebus spreads his rays;
How she observes him in his daily walk,
Still bending towards him her small slender stalk;
How when he down declines she droops and mourns,
Bedewed, as 'twere, with tears till he returns;
And how she veils her flowers when he is gone.
When this I meditate, methinks the flowers
Have spirits far more generous than ours,
And give us fair examples to despise
The servile fawnings and idolatries
Wherewith we court these earthly things below,
Which merit not the service we bestow.

From the time of Withers the poets treated the Marigold very much as the gardeners did—they passed it by altogether as beneath their notice.

Marjoram.

- (1) *Perdita*. Here's flowers for you,
Hot Lavender, Mints, Savory, Marjoram.
Winter's Tale, act iv., sc. 3.
- (2) *Clown*. Give the word.
Edgar. Sweet Marjoram.
Lear. Pass. *King Lear*, act iv., sc. 6.
- (3) The Lily I condemned for thy hair,
And buds of Marjoram had stolen thy hair. *Sonnet 99*.
- (4) *Clown*. Indeed, Sir, she was the Sweet Marjoram of the Salad, or rather the Herb-of-grace.
All's Well that Ends Well, act iv., sc. 5.

In Shakespeare's time several species of Marjoram were grown, especially the Common Marjoram (*Origanum vulgare*), a British plant, the Sweet Marjoram (*O. Majorana*), a plant of the South of Europe, from which the English name comes, and the Winter Marjoram (*O. Heracleoticum*). They were all favourite pot herbs, so that Lyte calls the common one "a delicate and tender herb," "a noble and odoriferous plant;" but like so many of the old herbs, they have now fallen into disrepute. The comparison of a lady's hair to the buds of Marjoram is not very intelligible.

Marybuds (see Marigold).

Medlar.

- (1) *Apemantus*. There's a Medlar for thee, eat it.
Timon. On what I hate I feel not.
Apemantus. Dost hate a Medlar?
Timon. Ay, though it looks like thee.
Timon of Athens, act iv., sc. 3.
- (2) *Lucio*. They would have married me to a rotten Medlar.
Measure for Measure, act iv., sc. 3.
- (3) *Touchstone*. Truly the tree yields bad fruit.
Rosalind. I'll graff it with you, and then I shall graff it with a Medlar; then it will be the earliest fruit in the country, for you'll be rotten ere you be half ripe, and that's the right virtue of the Medlar.
As You Like It, act iii., sc. 2.
- (4) *Mercutio*. Now will he sit under a Medlar tree,
And wish his mistress were that kind of fruit
As maids call Medlars when they laugh alone.
Romeo and Juliet, act ii., sc. 1.

The Medlar is an European tree, but not a native of England; it has, however been so long introduced as to be now completely naturalized, and is admitted into the English flora. It is mentioned in the early vocabularies, and Chaucer gives it a very prominent place in his description of a beautiful garden:—

I was aware of the fairest Medlar tree
That ever yet in alle my life I sie,
As ful of blossomes as it might be;
Therein a goldfinch leaping pretile
Fro' bough to bough, and as him list, he eet
Here and there of buddes and flowres sweet.

The Flower and the Leaf.

And certainly a fine Medlar tree "ful of blossomes" is a handsome ornament on any lawn. There are few deciduous trees that make better lawn trees. There is nothing stiff about the growth even from its early youth; it forms a low, irregular, picturesque tree, excellent for shade, with very handsome white flowers, followed by the curious fruit; it will not, however, do well in the north of England or Scotland.

Shakespeare only used the common language of his time when he described the Medlar as only fit to be eaten when rotten. Chaucer said just the same:—

That ilke fruyt is ever longer the wers
Till it be rote in mullok or in stree—
We olde men, I drede, so fare we,
Till we be roten, can we nat be rype.—*The Reeve's Tale.*

And many other writers to the same effect. But, in fact, the Medlar when fit to be eaten is no more rotten than a ripe Peach, Pear, or Strawberry, or any other fruit which we do not eat till it has reached a certain stage of softness. There is a vast difference between a ripe and a rotten Medlar, though it would puzzle many of us to say when a fruit (not a Medlar only) is ripe, that is, fit to be eaten. These things are matters of taste and fashion, and it is rather surprising to find that we are accused, and by good judges, of eating Peaches when rotten rather than ripe. "The Japanese always eat their Peaches in an unripe state. In the 'Gartenflora,' Dr. Regel says, in some remarks on Japanese fruit trees, that the Japanese regard a ripe Peach as rotten."

There are a few varieties of the Medlar, differing in the size and flavour of the fruits, which were also cultivated in Shakespeare's time.

H. N. ELLACOMBE.

(To be continued).

English Names for Orchises.—The Rev. H. N. Ellacombe in his "Plant-lore of Shakespeare" says:—"The Orchis, though so common, is without an English name, for though I have asked country people for its name I have never obtained one." Here, in Kent, Orchises are called by country folks "Keatlegs" and "Neatlegs," in allusion, I suppose, to the shape of the tubers resembling a calf's foot; this relates to the early purple Orchis, *O. mascula*. —JOHN MARTEN, *Chilham, Canterbury.*

THE COLORADO BEETLE.

THE ninth annual report, recently arrived, on the noxious, beneficial and other insects of the State of Missouri, by the State entomologist, Mr. C. V. Riley, contains a section of the Colorado beetle which, being official information, is of interest to Europeans. During the past year the insect has swarmed in most of the New England States, and especially on the seashore. At many places in Connecticut the beetles were washed ashore in such numbers in September as to poison the air, and the captain of a New London vessel found that they boarded him in such numbers while at sea that the hatches had to be closed. A map is given showing its eastern progress, the line of most rapid spread from Colorado being along the line of greatest human travel and traffic. When the beetle was first studied, it was calculated it would not reach the Atlantic till 1881; but it has undoubtedly availed itself to no inconsiderable extent of every means of transportation afforded to other travellers, and often got a lift on eastern-bound trains, and most probably crossed the more barren plains bordering its native confines through man's direct agency—*ie.* by being carried. It has travelled in a direct eastern line 1500 miles since 1859. There are reasons why it has not spread so rapidly along the southern as along its northern line of march. The first is, the Potato is not in such general cultivation along the southern line; the second is, that the insect is northern rather than southern in its native habitat. The next reason stated is of greater interest to Europeans—*viz.*, that, while it cannot thrive where the thermometer ranges near 100° Fahr, the intensity or length of winter will hardly affect it, except in reducing the number of annual broods, and, consequently, its power of multiplication. The state of dormancy once entered into, it may continue a month or two without harm. Mr. Riley has noticed that as the insect has spread over the country, it has become modified in habit and has increased the number of its food plants. It has also undergone considerable modification, so that old descriptions of the species no longer hold good in all cases. This is very important where, in the accident of its travelling on ships, it is necessary to decide whether a specimen is *Doryphora decem-lineata* or not. Mr. Riley says that he has seen hosts in their north-easterly spread through Iowa and Wisconsin, in which the ground colour is white rather than yellow, and the size not more than a half that of typical specimens. The ornamentation of the elytra and legs has also varied, and the black line along the elytral suture is as obsolete

as in *Doryphora juncta*. In discussing the probability of its introduction into Europe, Mr. Riley replies to the paper by Mr. Bates published in the "Journal of the Royal Agricultural Society of England," in which he argues that because no American beetles have been acclimatized in Europe, it is not likely the *Doryphora* will be. Mr. Riley mentions that *Bruchus pisi* and *Tenebrio obscurus* have been acclimatized, and further points out the especial powers of adaptation to new conditions the Potato beetle has shown. There are hundreds of North American insects—and some of the most injurious, too—which no one fears will ever establish themselves in Europe, because they are restricted, and have for years been

restricted, to certain geographical areas. But the Potato beetle has already shown that it is a remarkable exception to this restriction. Should it ever reach England and establish itself, it would enjoy the temperate climate of that country and thrive. —"Times."

BOMBYX PITYOCAMPA.

THE account so interestingly given by "A. M.," in THE GARDEN (see p. 412) of the Processionary Bombyx, that devours the Oaks in the Bois de Boulogne, reminds me of a still more destructive Bombyx that devastates the young Pines of the Riviera and some of the Mediterranean islands; it is the Bombyx Pityocampa of Boisduval. Whole tracts are not infrequently decimated by the ravenous caterpillars of this moth. Its depredations are mostly visible on *Pinus maritima* and *P. halepensis*, but it will attack occasionally the beautiful Stone Pine (*Pinus Pinea*) the classical Pine of Italy. Its habits of life bear a close resemblance to those of the Oak Processionary caterpillar, though the nests constructed are smaller and consist of more chambers, but like

The Colorado Potato Beetle. A.—The Beetle. B.—Larvæ at different ages. C.—Eggs. D.—Pupa. E.—Caterpillar. F.—Wing case, showing the stripes.

those of their congeners, they, too, have one main exit and ingress for their foraging parties. Again, there is a difference in their manner of transformation. As your correspondent justly remarks, the Processionary caterpillar of the Oak makes up within the web and so assumes the pupa state; whereas the Pine Processionary, when full fed, passes into the ground, therein to await its transformation. The larvæ are both furnished with urticating hairs, which irritate and inflame the skin by contact. As in the case of our Gold-tail, the abdomen of the moth is provided with a tuft of wool for the purpose of covering her eggs with the down. A variety of the Pine Processionary, which is much smaller, is reported to occur in Northern Germany; I have not seen it.—PETER INCHBALD, *Hovingham Lodge, York.*

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Camellias that flowered early during the winter, and were immediately afterwards put in a little warmth to make growth, will have set, and the buds developed to a considerable size; they must not be kept in heat too long, or they will open their flowers before the time required. If the earliest plants be urged on too forward at this time, it is impossible to retard them afterwards; through inattention in this matter I have frequently seen *Camellia* flowers opening by the end of August and through September that were not wanted before Christmas. Plants that are sufficiently forward should be at once moved into a cool house, where they will receive plenty of air and be shaded from the sun; see that they do not want for water, as if ever the soil gets quite dry after the buds attain a good size, they will most likely drop, although this may not occur till a long time afterwards, and may not be attributed to the real cause by those not intimately acquainted with the habit of the plants. Any plants that have been hitherto later in blooming than desired should be kept longer in warmth, for it is in the earlier stages of bud-development that the time of their flowering can be regulated, any attempt at forcing them into bloom by the application of heat through the autumn and winter generally resulting in the loss of the buds. Those that did not flower till late in the spring will now be making active growth; they will be benefited by the application to the roots once a week of a mild infusion of soot-water, say as much soot as can be held in the hand to two gallons of water; this will assist the plants in making growth, will give the foliage a healthy, dark, glossy green colour, and will also help to banish any worms that may have got into the pots. Those plants that make their growth late require more shading than the earlier ones.

Azaleas.—Of these the latest flowered should now be encouraged to make growth by keeping the house or pit moist with less air than the generality of greenhouse plants require. All except the small-leaved varieties need little or no shade, save in the very hottest weather, and that for a few hours in the middle of the day. Where *Azaleas* are much shaded whilst making their growth, the leaves always become weak and so far devoid of substance that they fall off in large quantities in the autumn, which has a correspondingly weakening effect upon the roots. Where a house or pit can at this time of the year be devoted to them and such plants as *Camellias* that are making their growth, there is little difficulty in giving them the treatment they require; but where they have to be grown in a mixed greenhouse with the usual occupants, there is no alternative but to make a compromise betwixt the several requirements of the various plants; in this case they should be placed at one end of the house where the shading can be regulated as necessary, and the syringe freely used without wetting those subjects that do not need it, admitting the air that is wanted at the opposite end to where they are ranged.

Pelargoniums and Fuchsias.—Those large-flowered *Pelargoniums*, that were some time ago recommended to have the points of their shoots pinched out so as to induce their flowering after the earlier bloomers were over, should now have weak manure-water given them twice a week; if neglected in this respect the lower leaves will assume a sickly yellow condition, and the flowering be proportionately deficient. *Fuchsias* struck from cuttings in the spring and required to bloom late in the summer should again have the points of their shoots pinched out, and any flower-buds they may have formed picked off; neither must they have their roots confined in too small pots, as this, more than any other cause, will stop their growth and induce them to form flowers sooner than they are required. The earlier plants that are now blooming should have all seed-pods picked off as soon as the flowers have dropped, as the production of seeds is more exhausting to *Fuchsias* than flower-bearing. Given them liquid manure every other time they are watered, but it must be in a highly-diluted state, as if given them so strong as many plants will bear it causes the flower-buds to drop off. A free use of the syringe two or three times a week will keep red spider in check.

Dahlias should be planted now. To grow these well they should occupy a position away from trees, the shade of which, when even ten or a dozen yards distant, draws them up weakly, the roots also being equally injurious in impoverishing the soil; high walls have a similar influence, but to a less extent, in causing weak growth, nevertheless the position they occupy should not be exposed to strong winds, otherwise, even with the most careful staking and tying, they get broken. *Dahlias* are quick growers and gross feeders, and can scarcely have the soil made too rich for them; plant 6 ft. apart, with a stout stick

to each, to which tie them at once. It is a good plan to cover the soil for 1 ft. round them with half an inch of sand, over which slugs do not like to travel; where these are numerous means must be taken for their destruction or prevention, by dusting the surface near the plants with a little soot and lime, renewed as often as it is washed down by rain until they get sufficiently strong; the slugs should also be sought for morning and evening. In addition to the ordinary varieties there is now a section of small kinds, known as bouquet *Dahlias*, the flowers of which are not much larger than those of a *Ranunculus*; they are profuse bloomers, and, when used for cutting to fill vases or baskets, are much superior to the large kinds; their general treatment is similar to that required by the large-flowered section, with the exception that there is no necessity for thinning out the shoots to the same extent.

Apricots and Peaches.—This year *Apricots* are in most places a failure through the sharp frosts that we have lately had, which killed the fruit when as large as marbles; yet it is necessary to treat the trees, so far as their general management is concerned, so as to prepare them for another year. Mistakes in this matter are frequently made by those who have not had much experience in fruit culture by leaving the trees uncared for during those seasons that they have failed to fruit. They should be examined now, and all superabundant growth removed, retaining those shoots that are in the best position for laying in. Continue to destroy the grubs rolled up in the leaves so long as there is any appearance of their being present. Keep a good look-out for mildew on *Peaches*; it will be found to attack first the young leaves on a few of the branches, for if allowed to remain unmolested, in a very short time it will affect the whole tree. A thorough syringing with Gishurst, in the proportion of 2 oz. or 3 oz. to the gallon of water, will destroy it, but to be effectual the liquid must reach every affected part; dusting with flowers of sulphur, using one of the old-fashioned sulphur puffs, is equally destructive to the parasite. The advantage in the use of the puff over the more common expedient of dredging it on from a small bag made of gauze or fine net, is that the under surface of the leaves can be reached as well as the upper; the sulphur may be allowed to remain on for a week, and be then washed off with the syringe. In too many places *Peaches* on open walls will require little thinning, the sharp nights having already effected too much in that respect; but where they happen to be too thick this necessary operation should be at once carried out.

Gooseberries.—Keep a good look-out on these for caterpillars, which in some places are now making their appearance. If the grubs be detected whilst in a small state and confined to a few leaves on probably a single branch, they can be summarily dealt with by crushing betwixt the thumb and fingers, whereas if allowed to spread they quickly run over the whole tree, in which case it becomes necessary to use the Hellebore mixture; powdered lime or even dry road dust is distasteful to them, and causes them to fall off, but unless destroyed then they will soon recommence their attacks on the trees.

Raspberries.—There is often a great waste of strength in the canes by allowing them to produce a greater number than can be retained for bearing the ensuing year, and which necessarily have to be cut away; to avoid this, and concentrate the energies of the plants in the production of the present season's fruit and the growth of next year's bearing wood, the young shoots that spring up from the bottom should now be thinned to within something near the required quantity. In the case of young plantations that have not yet attained their strength, two or three bearing shoots will be enough—those that are stronger may have half-a-dozen. In thinning the young shoots it is not sufficient to cut or break them off level with the ground, for if so treated they will quickly spring again. I have found an ordinary planting trowel the best implement to use for the purpose, removing 1 in. or 2 in. of the soil, whereby the shoots can be taken off directly from where they spring, in all cases retaining the strongest. The ground amongst these, as well as *Gooseberries* and *Currants*, should be again hoed over; if this be attended to sufficiently often the weeds can be effectually kept down with comparatively little labour; delay in this work often causes the part of the garden devoted to these fruits to have an untidy appearance, and be a source from which the seeds of weeds of a light character are carried by the wind to the surrounding portions of ground.

Tomatoes should now be planted; they may with advantage be grown wherever there is a small portion of wall at liberty, as is often the case between fruit trees; a south wall is the best, but they will frequently succeed on a western or eastern aspect; on the two latter I should recommend the greater part of the shoots being continually pinched in close—so as to bring them into bearing early; in all cases it is better to confine *Tomatoes* to a much less number of shoots than is

often done, thereby enabling more plants to be grown on a given space. The thinner the shoots are kept, the earlier they produce fruit. In warm districts Tomatoes will frequently succeed on a sheltered border fully exposed to the sun; plant them out singly, using two or three sticks to each plant for support, to which they must be kept regularly tied as the growth advances, otherwise, from their fragile nature, they get broken by the wind. Where they are so grown, the ground is better for being poor, as their natural habit of making too much growth is still further increased where the soil is rich. The plants should stand 3 ft. apart each way, so as to avoid their shading each other.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

June 4.—Sowing Snowball and American Red-top Turnips among Currant bushes. Planting White Cape, Walcheren, Hammond's White, and Grange's Cauliflower; also Backhouse's White, Dilcock's Bride, Knight's Protecting, Reliance, and Cornish Broccoli. Plunging pot Roses in the sun, in order to get their wood well ripened. Mulching Strawberries and Raspberries. Earthing-up Potatoes, Peas, and Cauliflowers. Syringing Azaleas infested with thrips with Gishurst Compound. Manuring and digging land for Winter Greens. Tying Bath Cos Lettuce, thinning Leeks, watering main crops of Strawberries, and afterwards netting them; also thinning second-sown Beetroot, and hoeing among Globe Artichokes.

June 5.—Potting newly imported Masdevallias. Shifting seedling Petunias into 5-in. pots, and established plants into their flowering pots. Planting Scotch Kale, Cottager's Kale, Brussels Sprouts, Savoys, and Autumn Cabbages; also May-sown Lettuce. Putting in cuttings of Anne Boleyn Pinks under hand-lights. Re-arranging Dendrobe-house, and putting cinders on the stages on which to place the plants. Watering Calceolarias, Perillas, Centaureas, and Dahlias. Top-dressing pot Roses with horse manure and loam, mixed together in equal quantities. Cutting Laurels, and edging and raking flower beds and borders. Sticking Scarlet Runners and Peas, and hoeing between rows of Parsley.

June 6.—Potting Caladiums, Panicums, and Alternantheras for dinner-table decoration; also potting Ten-week Stocks and Asters, and shifting standard Heliotropes into 12-in. pots for conservatory decoration during the autumn. Sowing Broad Beans amongst Currant bushes. Planting Black Hamburg and Muscat of Alexandria Vines. Pricking out Wallflowers. Turning and watering manure for Melon and Cucumber beds. Staking Carnations, Pinks, Dahlias, and annals. Watering early Peach-house and exposing the fruits which are ripening to the full influence of the sun, leaving more air on the house night and day. Plunging Tuberoses that are coming into flower in pits. Raking round Rose trees and preparing more land for late Peas.

June 7.—Shifting large Cockscobs into their flowering-pots. Tubbing a large Jasmine and *Lapageria rosea*. Planting Winter Greens, Vegetable Marrows, and Tomatoes. Layering Keen's Seedling and Garibaldi Strawberries in small 4-in. pots. Putting in cuttings of Kalosanthes, double Wallflowers, and *Salvia splendens*. Staking Heliotropes, and drawing drills for planting Winter Greens, &c. Hoeing among Gooseberry and Currant trees; also between Raspberries. Sticking more Peas, Beans, and Scarlet Runners. Watering flower garden thoroughly where the soil has become dry. Pegging down all plants that require it. Thinning Plums, Peaches, and Nectarines where not already done, and nailing in the longest of the shoots.

June 8.—Shaking out plants of *Phalenopsis Scbillieriana* that appear unhealthy, and after washing the roots clean, replacing them in fresh baskets. Taking up Chrysanthemums from open ground and potting them for conservatory decoration, and shifting Globe Amaranthus into 10-in. pots. Sowing Radishes, Lettuces, and Mustard and Cress. Planting Cauliflowers in heavily-manured trenches. Putting in cuttings of Begonias and other fine-foliated plants. Thinning Onions and Turnips, earthing-up Cucumbers, and hoeing among Gooseberry trees. Cleaning out water-tanks, clipping Yew trees, and weeding and hoeing old Asparagus-beds. Washing Camellias, in order to free them from black fly.

June 9.—Potting a few Roses into 12-in. pots, and shifting latest-struck Chrysanthemums into larger pots. Sowing Neapolitan and Drumhead Cabbage Lettuces; also Paris Green and White Cos. Planting April-sown Cabbages and Cauliflowers; also Ice-plants and

Gourds. Pricking off seedling Primulas and placing them in a cool frame. Dusting soot and lime on Onion-beds, with a view to keep down the maggot and improve the health of the plants. Thinning Apricots a second time. Watering Orchard-house trees; also Strawberry-beds. Picking insects off wall fruit trees, and afterwards syringing them with soft water. Throwing out more Celery trenches, and earthing up Cauliflowers and Potatoes.

Hardy Flowers.

ANEMONES.—Some patches of these planted somewhat late in the open border are now blooming freely. The roots had been kept for something like three years in a dry state, and yet there are but few failures. The flowers are rather small because planted late, but a mulching with a little good manure, and some liquid manure-water in a rather weak form is increasing the size of the blooms, and their brilliancy of colouring. A few of the best varieties are being marked for more select treatment next year. They will be carefully lifted in the autumn, and planted in well prepared beds much earlier than this season. A good bed of Anemones might be planted to flower in May and June, and the rows made sufficiently wide to admit of Asters being placed between them. In this way a good useful bed for cutting from for the season might be secured.

CAMPANULAS.—Some of the dwarf growing species, such as *C. garganica*, *pumila*, *turbinata*, and *Barrellieri* are now coming into bloom. They are all in pots in a compost made up of the siftings of mortar-rubbish, leaf-mould, and loam, in which they do well. Some of the varieties of *C. turbinata* are well worth attention; they have a dwarf, tufted growth, and large and handsome erect bell-shaped flowers. At Chiswick, Mr. A. F. Barron has planted out a few beds of these which when in flower will well repay inspection. Of the large growing herbaceous Campanulas, *C. persicifolia* and its white variety which is known as *coronata*, and *C. Van Houttei*, a summer-flowering plant with handsome purple blue flowers, well deserve attention. In some old-fashioned gardens *C. carpatica* and *C. carpatica alba* are used as edgings and ribbon lines, and with considerable effect.

ECHEVERIAS.—Old plants of *Echeveria secunda glauca* and *E. metallica*, kept over from last summer in pots, are now blooming freely. *Pachyphytum roseum* also deserves mention. It requires a considerable amount of frost to kill the latter in a greenhouse if the soil be kept dry during winter. They are now furnishing charming drooping spikes of brightly coloured flowers. The *Pachyphytum* can be easily propagated by laying a few of the fleshy leaves on the surface of the soil in which the plants are growing. The more delicate *P. bracteosum* can also be propagated in the same way, but not with so much certainty.

FOXGLOVES.—Well established plants of these are now growing freely, and will require to be tied to stakes as a security against wind waving. A good soaking with water should be occasionally given, as the thick layers of leaves prevent any rain from getting to the roots. Some seed should be sown without delay to furnish a batch of plants for next season.

PENTSTEMONS.—To get a good bloom early in the summer, some plants raised from seed early in the spring of last year, and which bloomed in the autumn, should be kept through the winter. Such plants have grown in a large bush-like size, and are commencing to throw up their flower-stems. Young plants raised from seed sown in August of last year or early this spring, come in well to succeed them. The larger plants form conspicuous objects in the raised border; but for planting out in beds smaller plants are to be preferred. In all the attempts made to improve the Pentstemon and add to the colour of its flowers, we are yet without a blue equal to that of the beautiful *P. Jeffreyanus*, a kind which should have a place in every collection.

RANUNCULUSES.—These are now getting very gay, and hot sunshine soon dims the lustre of the flowers; therefore if a little shading can be employed their beauty will be thereby prolonged. Surface stirrings, top-dressing, and a good watering occasionally are absolutely necessary in the case of beds of this beautiful flower; and an occasional syringing in the evening is also of great advantage. The old scarlet Turban Ranunculus is now very gay in some of the market gardens round London. The earliest plantings of it are made in November, and continued till February and March.

STOCKS.—Plants of these from seed-pans and boxes should be got out into beds without delay. The soil must be good for Stocks if fine spikes of bloom are to be had; and in addition to manure a quantity of leaf-mould is a great assistance. The young plants require close attention, as slugs are apt to attack them and eat them up bodily: a dressing of lime is as good a remedy as can be applied. Stocks require every encouragement to grow into size before the

plants begin to flower. Mulching with manure, and occasional watering with liquid manure are great aids as regards the production of fine heads of bloom.

ZINNIAS.—Like Stocks Zinnias require planting out without delay. The single and double varieties alike require very rich soil in order to bring them to perfection both as regards size and colour. The double Zinnias now in cultivation are simply marvellous when finely grown, and well repay cultivation. In many parts of the country they are finely shown at exhibitions, at which they are always an attractive feature. D.

FLOWER SERVICES IN CHURCHES.

Of the various decorative adjuncts of public worship which have come to be included under the comprehensive misnomer of Ritualism, there is one against which it might seem difficult for the sternest Puritan to frame a plausible indictment. Whatever sacrificial or other theological significance, obnoxious to Protestant criticism, may be attached to chasubles, caddles, or genuflections, the flowers which form the natural charm of our gardens, and the purest and sweetest, if not the choicest, ornament of our drawing-rooms, cannot surely be other than graceful and acceptable in our churches. We are not sure, indeed, that this process of reasoning, simple as it appears, has always been allowed, and, in fact, with the scanty exception of Holly sprigs at Christmas, the use of floral decoration to symbolize festal joy is of comparatively recent introduction into English churches; but the obvious grace and appropriateness of such a usage has done much to disarm opposition, and we believe we are right in saying that in many churches which would be loosely described as moderate Evangelical, or very moderate High Church, where vestments and lights are regarded as an abomination, the altar is fragrant on high festivals with a profusion of blooming nosegays. This result may, perhaps, be due in part, as the reporter of last Tuesday's ceremony in the "Daily Express" suggests, to the happy thought of the rector of St. Katherine Cree in introducing, nearly a quarter of a century ago, a special Whitsuntide flower service into that historic fane for the benefit mainly of the younger part of his congregation. Yet it must in fairness be admitted that, if the character of a religious usage is always to be religiously defined by its origin, a much stronger case might easily be made out against the association of flowers with Christian ritual than against any of those forms and ceremonies which the combined wisdom of Lord Penance and the Privy Council has so elaborately condemned. Chasubles and copes, according to the most probable view, were simply derived from the Roman lay dress of ordinary life under the Empire; the worst that can be urged against them is that they were possibly modelled on the official dress of the Levitical priesthood, and thus carried with them a certain sacerdotal association, though of this there is no evidence. The religious use of flowers, however, is directly connected with some of the most questionable incidents of Pagan worship, though we are not aware that any special Christian festival took the place of the "Floralia," as St. Valentine's Day appears to have taken the place of the "Lupercalia." May is always more or less a festal season of the Church, but the date is determined on wholly independent grounds. And the modern Roman Catholic custom of consecrating the month to the honour of the Virgin Mother, though due, no doubt, to the same instinctive sense of fitness which fixed that period for the feast of the goddess Flora, is of far too recent origin to have been borrowed directly or indirectly from any usages of Pagan Rome. As Dr. Newman puts it—

We give to thee, May, not because it is best,
But because it comes first, and is pledge of the rest.

It may seem strange, however, that other than innocent ideas should ever have been connected with this feast of flowers, and a word of explanation will not be out of place.

For some reason or other the garden was redolent in classical literature of associations the reverse of fragrant. Priapus, of evil repute, was its presiding deity. It gave its name to the most sensual and unmanly of the ancient schools of philosophy, as is implied in Præd's familiar lines on St. Paul preaching at Athens—

And the fair garden's Rose-encircled child
Smiled unbelief, and shuddered as he smiled.

Flora, the Roman goddess of flowers, according to the received tradition retailed by Plutarch, Macrobius, Lactantius, and others, was a courtesan, and left to the city wealth acquired by her profligacy. The date and source of the legend is questionable, but there can be no question at all as to the gross and unbridled licentiousness of the Floralia, or games said to have been instituted in her honour under Romulus, and lasting five days, from April 28 to May 2. Pliny assigns the

origin of her feast to the command of an oracle in the Sibylline books in 238 B.C., but we have little authentic information about it till the observance was restored some sixty years later by the ædile Servilius, acting under orders of the Senate, because the vegetation that year (173 B.C.) had suffered from the inclemency of the weather. Ovid has discussed at length in the Fifth Book of the "Fasti"—

Quare lascivia major
His foret in ludis, liberiorque jocus.

And the nature of the solemnity is still more unmistakably illustrated by Martial, "Ad Catonem nimis Ansterum" (Epig. i. 3). It is related that on one occasion Cato desired to be present at the celebration, but when he found that the people were ashamed to call for the public exposure of the actresses on the stage, according to custom, while he was there, he retired in order not to interrupt the proceedings. It is probable, however, that the Floralia were originally rural festivals observed both in Italy and Greece, which became corrupted after their introduction into towns, and this may have given rise to the uncomplimentary story of the goddess Flora, with whose worship the celebration had then come to be connected. The Christians of course borrowed nothing from these orgies, but they had touching legends of their own about visions of martyrs who consoled their surviving friends with gifts of flowers from Paradise, and the like, and the use of flowers as an adjunct of Christian worship is of very early date.

We have already intimated that the church of St. Katherine Cree, where Dr. Whittemore has established the children's flower service, possesses an historical interest of its own. It was consecrated by Laud when Bishop of London in 1631, and Hume has devoted several pages to what professes to be a detailed account of the ritual used on the occasion, and an indignant comment on the "ceremonies to which Laud sacrificed his own quiet and that of the nation." But one may, perhaps, be permitted to doubt the justice of his strictures so far as it depends on the accuracy of his report, for it does not require the skill of a liturgical expert, or anything beyond the most superficial acquaintance with the Eucharistic service of the Church of England or the Church of Rome—which last Laud was accused of imitating—to see that the ridiculous antics ascribed to him bear not the slightest resemblance to either rite. If, indeed, Hume's account is to be at all literally taken, this most prelatial of prelates must have performed the Communion Service—as, according to a famous Privy Council Judgment of twenty years ago, he was bound to perform it—with the Prayer of Consecration left out. That he pronounced a solemn malediction on any who should divert to profane uses the sacred building which he was engaged in dedicating is possible enough; and it is some consolation in these levelling days, when so many of the City churches are either doomed or actually destroyed, to reflect that St. Katherine Cree still retains unchanged the sacred character originally conveyed to it by the last of the great archbishops, whose biography Dean Hook has left us. Nor is it unreasonable to assume that Laud, who had a keen eye for the didactic aspects of ceremonial, would have viewed with approval the striking spectacle presented by the interior of St. Katherine's on Tuesday evening last. The following description is taken from the fullest report of the service we have come across, and it suggests a very pleasing picture to the eye:—

The fame of the flower service has spread abroad, and from many parts of the metropolis listeners gather together to hearken to the genial discourse that is especially addressed to the younger portion of the congregation on these occasions. Last evening, from an early hour, Leadenhall Street was crowded by these, their destination easily recognizable by the fresh bouquet of spring flowers that all attending are requested to bear as a badge. Still more densely thronged was the interior of the sacred edifice, and it is doubtful whether it had ever held so many worshippers since that January day in 1631, when Laud pronounced within its newly-raised walls the solemn denunciations against those who should pollute them by musters of soldiers, or twisted, profane law courts, which were in after years to be twisted by men thirsting for his blood, into one of the acts of accusation that were to secure to him the crown of martyrdom. Very full of contrast at all times is this quaint specimen of the architecture of the days of the first Stuarts, with its strange blending of the Pointed and the Italian styles, its mullioned windows and Corinthian columns, its goined ceiling, with the intersecting ribs adorned with armorially enriched bosses, and its Ionic pilasters crowned by an entablature and pediment. On its plain Gothic walls the monument where Sir Nicholas Throckmorton, some time Chief Butler of England to Queen Elizabeth, and Ambassador to France and Scotland, reposes at full length, in ruff and plate armour of equal stiffness, beneath a canopy of black marble, ornamented with skulls, crossbones, and hour-glasses, and that setting forth the virtues of Richard Spenser, Turkey merchant, look equally out of place; as to the old-fashioned pews of time-darkened wood, which we have the promise of the rector are shortly to be swept away, and the pulpit recalling in outline a carved wooden goblet. But last night a yet greater contrast was afforded by the inmates of the pews in question. The fresh young faces of children peered up from their box-like recesses, while on the ledges in front of them bloomed bunches innumerable of flowers, far eclipsing in brilliancy of colour the rich hues of the armorial

hearings emblazoned in that great east window, the radiating mullions of the upper part of which recall by their arrangement the terrible wheel to which the Alexandrian virgin was doomed by the tyrant Maximin. One and all had obeyed the request to bring bouquets, and the church was fairly scented with their fragrance.

Hymns were sung composed for the occasion, and Dr. Whittemore preached an appropriate sermon, addressed especially to his younger hearers, from the words of Habakkuk (iii. 17, 18), "Although the Fig tree shall not blossom, yet will I rejoice in the Lord," in the course of which he informed them that the Church would be restored, and the unsightly pews removed, before this time next year. The aisles as well as the pews were crowded, and many parents were present with their little ones, who had been in the habit themselves of attending the annual flower service from childhood. The conspicuous success and popularity of the rite confirm the evidence supplied by the services formerly held at St. Lawrence Jewry and elsewhere of the excellent purposes to which City churches may be applied by incumbents who have a mind to utilize them instead of clamouring for their destruction. Lord Penzance's reign has already been signalized by the virtual closing of one such church, which used to be thronged with devout worshippers both on Sundays and weekdays. Let us hope that many City rectors may be found to emulate the active zeal of Dean Cowie, Dr. Whittemore, and Mr. Rodwell, and that "the three aggrieved," who "come to reform where ne'er they come to pray," may graciously condescend to leave their neighbours unmolested in devotions that are at least preferable to that "worship chiefly of the silent sort" for which our City churches have too long enjoyed an unenviable notoriety.—"Saturday Review."

SOCIETIES AND EXHIBITIONS.

FLOWER SHOW AT ORLEANS HOUSE, TWICKENHAM.

THIS Show took place on Friday and Saturday last, and, considering the liberal schedule of prizes which was provided, the exhibits, though good, were not nearly so numerous as might have been expected. They were arranged on Grass banks under two large tents. New and rare plants were exhibited by Mr. Bull, and attracted much attention. Amongst them we remarked good examples of *Dieffenbachia maculosa*, *Croton Disraeli*, and *C. triumphans*, *Maranta Massangana*, and *Dracæna Goldiana*, all plants possessing special interest. The same exhibitor also furnished a group of coloured-leaved new *Dracænas*. Mr. John Wills likewise showed *Dracænas*, as did also Mr. Legg, gardener to J. S. Rutter, Esq., Cleveland House, Clapham. Mr. Wills had likewise a group of new plants, amongst which we noticed *Arctocarpus Cannoni*, *Anthurium Doehardi*, *Maranta Leopardina*, and a painful of well-grown plants of *Bertolonia Van Houttei*. Roses in excellent condition were exhibited by Messrs. George Paul and Turner; amongst the most conspicuous kinds may be mentioned *Juno*, *Celine Forestier*, *Paul Verdier*, *La France*, *Maréchal Vaillant*, *Madame Willermoz*, and *Charles Lawson*, all beautifully in bloom. Roses grown in 8-inch pots were also shown by Messrs. Paul & Son and Mr. Moorham, gardener to Messrs. Christy, Kingston. Of Orchids, the only large collection came from Messrs. Jackson & Sons, who had well-flowered, healthy plants of *Sarcobolium retusum*, *Odontoglossum citrosum roseum*, *Vanda snavis*, *Dendrobium Devonianum*, and a remarkably attractive plant of *Cattleya Warneri delicata*. Messrs. Rolleston also showed Orchids, amongst which were *Cattleya Regnellii*, *Lelia purpurata*, and *Dendrobium thyrsoiflorum*. Palms and Ferns were well shown by Messrs. Hooper & Son and Mr. Wimssett, and collections of stove and greenhouse plants and Cape Heaths were contributed by Messrs. Jackson. Mr. B. S. Williams exhibited a miscellaneous group of plants, among which were healthy and well-flowered examples of *Genetyllis*, *Anthuriums*, *Odontoglossums*, *Sarracénias*, *Palms*, and *Dracænas*, the whole being edged with small *Crotons*, *Aralias*, *Rhopalads*, and Ferns, amongst which we remarked a neat little plant of the new *Adiantum palmatum*. Mr. Kinghorn, Richmond, had also an effective group of plants, amongst which were *Dieffenbachia Bausei*, *Croton Weismanni*, *Coccos Weddelliana*, and a beautifully-coloured plant of *Ananassa sativa variegata*. Mr. Ley, Croydon, furnished a good collection of Palms, *Crotons*, and *Marantas*; and Mr. Cornhill, gardener to J. S. Virtue, Esq., Outlands Park, had capital examples of *Dieffenbachias*, *Alocasias*, and a very fine plant of *Ananassa bract-ata variegata*. Fine-foliated plants were likewise shown in good condition by Mr. Legg, who had fine examples of *Dracæna Shepherdii*, *Cycas revoluta*, *Alocasia Lowii*, and a grand plant of *A. macrorrhiza variegata*. Indian Azaleas were contributed by Mr. Turner, Messrs. Jackson, Mr. Child, and Mr. Ratty; the last named exhibitor had a dozen standard plants, well-flowered, and devoid of that stiff, formal appearance too often to be found in exhibition plants, especially standards. Show and Fancy *Pelargoniums* were exhibited by Mr. Turner and Mr. James, both of whom had unusually fine plants laden with flowers. Conspicuous amongst the show varieties were *Triomphe de St. Mandé*, *Prince of Prussia*, *Duchess of Cambridge*, *Prince of Denmark*, and *Prince Leopold*; and amongst the fancy kinds the best were *Princess Teck*, *Ellen Beck*, and *Excelsior*. Table plants in 6-in. pots were contributed by Mr. Wills, Mr. Bates, Poulett Lodge, and Messrs.

Hooper & Sons; they consisted chiefly of *Pandanads*, *Crotons*, *Cupania filicifolia*, *Aralias*, and similar subjects. Amongst *Caladiums*, which were furnished by Mr. Morell, gardener to J. S. Rutter, Esq., and Mr. Cornhill, were good plants of *Edward André*, *Reine Victoria*, *Prince Albert Edward*, and the old, but still, in some respects, unsurpassed *bicolor splendens* and *Chantinii*. Mr. James showed well-grown herbaceous *Calecolarias*, and Mr. Bates had a finely-flowered group of *Gloxinias*. *Mimulus*, *Forget-me-Nots*, *Brompton Stocks*, and *Pansies*, came from Mr. A. Dean, Bedford. *Auriculas* in pots were shown by Mr. Turner, who also furnished a collection of cut blooms of *Tulips*. *Roses* in a cut state came from Mr. William Paul and Mr. Mayo, and Mr. Mott, Kensington, showed three hand bouquets. Messrs. Webber & Co., the only exhibitors of fruits, sent a capital basket of English-grown *Grosse Mignonne Peaches*, *St. Michael's Pines*, and baskets of *Muscata* of *Alexandria* and *Madresfield Court Grapes*, the last one of the best early *Grapes* in cultivation, being good alike in appearance and flavour. Messrs. Rolleston, to whom the arrangements of the show were entrusted, filled up all vacant spaces with choice flowering and ornamental-leaved plants from their nursery at Tooting.

OBITUARY.

MISS EMMA OSBORN.—This lady, the daughter of Mr. Robert Osborn, the first of the family connected with the Fulham Nurseries, died on the 25th ult. She was well known to many of the older frequenters of the nursery, and devoted herself to flower-painting, exhibiting occasionally at the water-colour exhibitions in London.

A Centenarian Gardener.—Few of the present generation can date from the year 1777, yet there has just passed from amongst our midst a man whose manhood was spent during the stormy period of '98. James Durham, whose life was spent in the service of Hans Hamilton, Esq., of Sheephill, as gardener for several generations, has just passed away at Blanchardstown, county Dublin. The latter years of his life were spent at Sheephill, where, by the kindness of Mr. Hamilton, he was enabled to spend the last twenty years of his life free from care. Most of his children being dead, he was followed to the grave in Mulhuddart churchyard by a numerous train of grand and great-grandchildren, and also by the numerous retainers of the Sheephill estate.—"Freeman's Journal."

NOTES AND QUESTIONS—VARIOUS.

Maive-coloured Lilies of the Valley.—All my Lilies of the Valley have come up very small this season, and there has not been one white amongst them. They have been a deep shade of maive. Is this unusual?—T. S., Gosport. [You have doubtless got *Convallaria rosea*, which is greatly inferior to the common *Lily of the Valley*.]

Lentils.—The price of Lentils in the west of London is 11. a lb.; abroad they are not half that price. When they become damp they are never really fit for use. They require no soaking before being cooked. The French boil them slowly for about half-an-hour, then drain off the water, add gravy, seasoning according to taste, and finish cooking them on a slow fire for about three quarters of an hour. Another mode is simply keeping them from burning by adding a piece of butter after draining off the water, with a small quantity of finely-chopped Parsley and Garlic.

"Rush Sunday."—A picturesque custom still lingers in the West of strewing the floors of the churches on Whit Sunday with Rushes freshly gathered from the meadows. This custom attains its highest perfection in the church of St. Mary Redcliffe, at Bristol. On "Rush Sunday" the floor is strewn with Rushes. All the merchants throw open their counters for the vicar to take his choice of their flowers; and the parrot, the lecturer, the choir, and the communion rails and table present a scene of great beauty.

Lantana Le Grenadier.—This fine high-coloured *Lantana* formed a prominent feature in a collection of six stove and greenhouse plants shown the other day at Renling. It was well grown and trained much as one would an *Aphelaxis*. The flowers are brilliant maroon flushed with orange, and the trusses being large and freely produced, the plant taken as a whole was most effective.—D.

Cauliflowers and Lettuces under Glass.—This is the kind of season when even the smallest amount of protection has a marked effect on early crops. I had a large pit filled with Cauliflower and Lettuce plants fit for planting out in March, but the unfavourableness of the season induced me to leave enough for a crop of both under glass; the Cauliflowers were planted about 1 ft. 6 in. apart, and the Lettuces between them. The latter have been as crisp as midsummer Lettuces, and we shall have plenty of Cauliflowers by the time the late Broccoli is over, although the lights have been off for some time and utilised in other ways.—J. Groom.

Lettuces under Glass.—I can fully confirm Mr. Hobby's remarks (see p. 399) regarding this subject. I tried the experiment this season and with good results, for I have cut Paris Cos Lettuces during these last three weeks, and shall be able to cut until those in the open ground are fit for use. I made my first sowing in January and another early in March, which will give me a good succession. Where early *Saxa* is in demand, I should recommend every one to try this plan; the trouble and cost are slight, compared with the quantity and quality of the produce.—F. BULLOCK, *Farnham, Götteshof*.

A Fertilizing Flower Pot.—One of the latest inventions is a "fertilizing flower pot," said to be made of earth, firmly compressed. In repotting, pot and all are transferred, when the pot becomes part—and a very useful part—of the soil. Such pots consisting of loam and cow-manure, and readily made in a mould, are very useful.—J. H.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLORAL DECORATIONS.

(WILD FLOWERS).

WHILE staying with a friend a few weeks ago in the neighbourhood of London, who regretted she could not have fresh flowers on her dinner-table as often as she could wish (having only a very small garden and no glass structure), I suggested that she might arrange a vase of wild flowers as a change, but the answer which I received was, there were no wild flowers to be had suitable for decorative purposes so near London. Now as there were several large fields, &c., not far from her residence, I thought it strange that no flowers could be obtained, so I went out on a ramble in quest of a few of some description, as I felt certain that in the hedgerows which I had seen there must be some; and my perseverance was rewarded, for I found several varieties which I arranged as I shall presently describe. First as to the stand in which they were grouped: I selected one of basket rock, as it looked more simple and rustic, and, to my mind, most in keeping with the flowers which I was about to arrange in it; its form was that of a flat tazza, above which was a very much smaller one supported gipsy-fashion on a tripod. The flowers which I found were as follows:—Hemlock, Buttercups, May, Bluebells, Vetches, and Ox-eyed Daisies; and in the way of foliage, Ivy, Grasses, and Hemlock leaves, the arrangement of which I shall endeavour to describe. Up the rods which formed the tripod and supported the top tazza, I twined trails of Ivy, selecting young shoots, as the leaves of these are always smaller and of a lighter shade than more matured sprays, and therefore better adapted for decorative purposes. I then took some sprays of Vetch, and twined these also up the rods and amongst the Ivy. I then took some Hemlock leaves and arranged them round the edge of the tazza, so as to droop outwards (these leaves have a pretty Fern-like appearance, and are well suited for this purpose), selecting some young and some of a more mature growth, so as to have as many varieties of shades of green as possible. Next came the May, this I had to break into small pieces, some of which I placed in the lower tazza to form a foundation for my other flowers; but much of this plant should never be employed in floral decorations, as its perfume is sickly, and unpleasant to many. I then worked in my Ox-eyed Daisies, Blue Bells, Hemlock, and Buttercups; the two last-named I placed above the other flowers, in order to give as light an appearance to the whole as possible. The upper tazza I arranged in a similar manner, with the addition of a plume of light Grasses, a few spikes of which I also placed amongst the flowers in the lower tazza round the centre-piece. I grouped four specimen glasses, in two of which were blooms of Hemlock and Buttercup, Grasses, and Hemlock leaves; in the other two Hemlock, pink Clover, Grasses, and Hemlock leaves. The leaves of the Hemlock picked for this purpose should be very young, or they will be found to be too large and coarse-looking. When the above arrangement was finished, it had a very pretty appearance, though composed, one might almost say, of a handful of weeds, which were picked within $6\frac{1}{2}$ miles of the centre of London.

ANNIE HASSARD.

TWO NEW AURICULAS.

ABSENCE from home prevented me sending you sooner some remarks on a few of the less well-known Auriculas which I saw at the Crystal Palace and at Manchester. However, they may be of use to other lovers of Auriculas who were not fortunate enough to have seen the two fine shows of the National Auricula Society. Mr. Simonite, of Sheffield, exhibited a seedling, called Frank Simonite, which is, indeed, a valuable addition to that rather weak class, the white edges. It is a fine, bold flower, a grand truss, and holds its head well up above its abundant foliage. It is circular, flat, and even; its paste is dense and smooth; the body-colour is a lovely

shade of violet. I am exceedingly glad to find that two such growers as Mr. Simonite and Rev. F. D. Horner are turning their energies towards violet, blue, and many body-colours in the edged flowers. For too long a time the old traditional law which forbid any body-colour except black, or only tolerated maroon, has operated injuriously on the popularity of the Auricula, by giving a sameness and tameness to the flower which its lovers sometimes were hard pressed to vindicate. But in the hands I have mentioned we may confidently look for a great increase of brilliancy by the introduction of those body-colours into otherwise well-pointed flowers. There is, however, in everything good the *aliquid amari*; and the bitter in the Auricula lover's cup is this, that Nature seems to have sternly laid down the law, that no shade of blue or violet in the body-colour shall co-exist with a bright gold tube. Alas, that it should be so! for, to my mind, a bright eye in an Auricula is as desirable, and a weak, dull, empty-looking one as unlovely, as in the human countenance. Happy will be the man whose patient care and skilled observation shall wrest from Nature the secret of this law, as he will then be on the fair road to brightening up the lovely but languid faces of Frank Simonite and C. J. Perry with a beaming golden eye. John Simonite is another of Mr. B. Simonite's white-edged seedlings. Being sent out by him—or rather shown by him, as it is not yet sent out—is guarantee of its high qualities. It is round, flat, and smooth, of course; the paste is good; the body-colour is black; the tube is only lemon-colour, but is not dull. Indeed, with such a body-colour there is no reason why it should not be far from dull, as black grounds often give the brightest of gold tubes. We may well expect that some future child of Mr. Simonite will be an improvement on this. Every judge has, more or less, to play the unpleasant part of *advocatus diaboli*, and, therefore, I am in duty bound to say that the weak point in John Simonite is a sunken tube. I believe, however, that sometimes this defect, though present in the seed-plant, wears away in course of time and cultivation. Let us hope this may prove the case with this very excellent variety.

FREDERICK TYMONS.

Cloghran, Co. Dublin.

CURIOUS EFFECTS OF GRAFTING COLEUSES.

LATE last summer I grafted certain kinds of Coleus, the most remarkable of which is Duchess of Edinburgh, grafted with Brillant de Vaise and Golden Gem. I kept them during the winter partially at rest, and in February I potted them and started them into growth on a gentle bottom-heat. As soon as they had made fresh leaves I found that Brillant de Vaise had inoculated the stock, the leaves on one shoot above and one below the graft having become spotted and mottled with dull yellow and reddish brown, with an occasional flake or two of the magenta rose-colour of Duchess of Edinburgh, while Golden Gem, on the same plant, remains unaffected. Some time back I removed the top of the stock which grew very vigorously, some leaves being wholly green, others dark velvety-crimson edged with green, and mottled and blotched with yellow and dull reddish-brown. Up to the present time this plant has not altered. Of the next two breaks which I took off and struck as one would cuttings, one is almost the same as Duchess of Edinburgh, with spots of yellow here and there, and some of the leaves are very beautiful, being pink, cream-colour, and light green; this is the prettiest shoot, but the slowest grower. The other is dark crimson edged with green, and very much mottled with amber; this is now becoming very attractive. I also grafted C. Brillant de Vaise on C. elegans, which has a yellowish-green ground heavily netted and veined with bluish-crimson. This was also inoculated, the leaves of the stock turning quite green. I also grafted others, on one of which I put five varieties, using C. Emile Chaté for the stock, and the following for grafts, viz.:—C. Merrimac, Lady Burrel, Duchess of Edinburgh, ruber, and Beauty of Widmore, but as yet no change has taken place; they all exhibit equal strength except the last, and that is on the centre shoot of the stock. I find that Duchess of Edinburgh, with its many and varied hues of colour, comes much brighter, and retains its leaves much longer if grafted upon C. Souvenir de Lierval.

R. H. B.

NOTES OF THE WEEK.

WISTARIA WREATHS.—In Mr. Robert Osborn's garden at Fulham I was charmed the other day at the sight of several specimens of *Wistaria garlanding* in the most natural way old Thorn trees and a standard *Magnolia grandiflora*. One is so accustomed to see the plant trained that its unique qualities as a free climber are seldom allowed fair play. The delicate wandering shoots running over the tree, and the blue racemes gracefully mingling with the Thorn flowers, form a lovely combination, and one which it is gratifying to know can be formed of simple hardy materials in the open air.—R.

TRICHONEMA RAMIFLORUM.—This pretty little denizen of the Riviera has been very effective during the bright sunshine of the last three days; it is one of the latest of the family to bloom. In size of flower it little exceeds *T. Columnæ*, but it is much brighter in colour, pale mauve marbled with darker lines and a yellow throat. The blooms are very numerous, and a patch of them when fully expanded is a very pretty sight.—H. HARPER CREWE.

AN INNOVATION AT SOUTH KENSINGTON.—The Council of the Royal Horticultural Society must have probably misapprehended the feeling that generally prevails among horticulturists, when it resolved to introduce the public presentation of the medals to exhibitors. Horticulturists are fond of exhibiting to the public gaze the plants and flowers that are the products of their industry and skill, but wisely shrink from making exhibitions of themselves. The first attempt at this awkward change at the usually pleasant meetings at South Kensington was not a very attractive spectacle: the loud voices of the speakers could not be heard in the lofty glass house. The prize winners answering their names and then crawling up the steps to the dignitaries above reminded one irreverent observer of the ascents to the throne in the Vatican, when a very high personage allows certain of the faithful the honour of kissing his slipper.

MUSCARI ATLANTICUM AND M. ARMENIACUM.—These two handsome Grape Hyacinths have been in full beauty during the last fortnight. The former was, I believe, first introduced into this country from the neighbourhood of Oran by the late Mr. Giles Munby, to whose kindness I am indebted for the few bulbs I possess. With the exception of *M. armeniacum*, it is the last of the family to bloom. It seems to come between *M. conicum* and *M. racemosum*, but is easily to be distinguished from both by its time of blooming and the colour of its flowers, which are a bright Prussian blue. *M. armeniacum* has long been cultivated by Messrs. Osborn, of Fulham, to whom I believe most of us are indebted for the bulbs we possess. My single bulb came to me from this source through Mr. Ellacombe. It has this spring thrown up no fewer than five heads of bloom which will, I hope, yield seed. Its flower-spike is longer than that of any other species, and the bells have a delicate lavender-mauve hue unlike those of the rest of the family.—H. HARPER CREWE, *Drayton-Beachamp Rectory, Tring.*

AOTUS GRACILLIMA.—This old-fashioned New Holland plant is seldom seen in good condition, but when well flowered, it is one of the most effective of indoor plants. Examples of it in the Pine-apple Nursery, grown in 8-in. pots, bear from ten to twelve long, gracefully-drooping branches, thickly beset with small, bright orange, *Genista*-like blossoms. If when in bloom good plants of this *Aotus* be placed in hanging baskets, the branches droop lightly over the sides and form attractive objects. A fine specimen of it was exhibited the other day at South Kensington by Mr. Ollerhead; it was 5 ft. or 6 ft. in height, and, being allowed to grow in a natural manner, its profusion of slender thickly-blossomed branches rendered it strikingly effective.—S.

DWARF COCKSCOMBS.—Cockscombs, when in flower, are attractive under any circumstances, but they are seen to best advantage in May or early in June, in the shape of neat little plants, suitable for placing in the front rows of conservatory stages. Some grown for this purpose in Mr. Hudson's garden, Clapham, are now in beautiful condition; the seed is sown in pans, and when the plants are up they are potted into 3-in. pots, and when the combs are visible the tops are taken off with two pairs of leaves attached to them, and inserted in 5-in. pots in sandy soil, and plunged in a brisk bottom-heat, and in a few days roots are formed; after that the combs speedily expand, and during May and June the cuttings form plants not more than 5 in. or 6 in. in height, each furnished with healthy green leaves and a brightly-coloured comb, measuring lengthwise from 6 in. to 8 in.—S.

LARGE TOMATOES.—At the Royal Horticultural Society's meeting, held the other day at South Kensington, Mr. Iggalden, of Ossett Hall, showed a dish of Hathaway's Excelsior Tomatoes, the largest and handsomest which we have seen so early in the year. They were the produce of plants growing in boxes placed at the end of a

Vinery, and Mr. Iggalden attributes his success to his having fertilised the flowers as fast as they expanded. Thus treated the fruit set quickly and grew much more rapidly than would otherwise have been the case. Fertilising the flowers would of course be impracticable where large quantities of plants are grown, but it is an operation that is amply rewarded by abundance of large, finely-shaped, smooth-skinned fruits of first-rate quality.—C. S.

BRITISH POLYGALAS.—Those interested in these small plants will find a good account of them by Mr. A. W. Bennett in the June issue of the "Journal of Botany," which, however, publishes the descriptions without the plates referred to in the text.

EARLY CHERRIES.—Cherries of large size and fine colour, though, as one might expect, not quite ripe, come now in great quantities to the London market from the neighbourhood of Avignon. Apricots from Spain continue to be very numerous and well-flavoured.

DENDROBIUM CONCOLOR.—Few Dendrobies are more showy than this when well flowered, and growing as it does on blocks of wood or stumps of Tree Ferns, suspended from roofs of houses, its large, pendent clusters of pale yellow blossoms are very attractive, and last in good condition for a long time. Excellent plants of it grown in this way are now flowering profusely in Messrs. Veitch's nursery at Chelsea.—W.

THE INNER TEMPLE GARDENS.—By the kindness of the Benchers these gardens are now open to the public every evening between the hours of six and eight o'clock. The privilege thus granted is taken advantage of principally by the poor children inhabiting the neighbouring courts and alleys, many hundreds of whom enter the gardens every evening. The gardens will continue open until the end of August.

RHODODENDRON JASMINIFLORUM.—This, one of the most beautiful of all tender Rhododendrons, is now flowering freely in a greenhouse in Messrs. Veitch's nursery at Chelsea. Its blossoms, which are borne in unusually large clusters, have a remarkably chaste, waxy appearance, and they are moreover very sweetly scented. Both as a decorative plant and for furnishing cut bloom, this *Rhododendron* has few equals. The spice-scented *R. Edgeworthi*, in the same house, is also bearing numerous large, white flowers, delicately shaded with pink, and the large, creamy-coloured *R. Veitchi* is likewise finely in bloom.—C. S.

TESTIMONIAL TO MR. WILSON.—It has been decided, at a meeting held on the 26th ult., to present a testimonial to Mr. F. W. Wilson, who has lately left the Crystal Palace after twenty-five years' service. Mr. Wilson's unflinching courtesy and thoroughly zealous efforts to promote and carry out successfully the various interesting natural history and other shows at the Crystal Palace have earned for him the respect of a wide circle of friends. Mr. C. E. Elliott, of the Ceramic Court, Crystal Palace, has consented to act as honorary treasurer and secretary, and he will be happy to attend to all communications in connection with the fund or receive subscriptions.

PRIZE ROSES.—Prizes, consisting of two silver cups of the value of ten guineas each, given by the Hon. and Rev. J. T. Boscawen, for Tea and Noisette Roses, at the Bath Show the other day, were awarded as follows:—Twelve varieties, three blooms of each, distinct—Silver cup to Mr. C. Turner, of Slough, for *Devoniensis*, *Maréchal Niel*, *Celine Forrester*, *Madame Willermoz*, *Niphotos*, *Gloire de Dijon*, *Safrano*, *Souvenir d'un Ami*, *Marie Van Houtte*, *Madame de St. Joseph*, President, and *Madame Falcot*. The cup in the amateurs' class was awarded to Mr. Charl. Clarendon Park, Salisbury, who showed, amongst others, good blooms of *Maréchal Niel*, *Catharine Mermet*, *Devoniensis*, *Celine Forrester*, *Amabilis*, and *Adam*.

NEW PARKS FOR SALFORD.—The Salford Town Council some time since determined to construct three additional parks—at Seadley, Broughton, and Ordsall—for the recreation of the rapidly-increasing population of that borough. Seadley Park was opened a year ago; the Albert Park, Broughton, was on the 12th ult. formally dedicated to the use of the public; and the park in the Ordsall district is expected to be completed in a little more than twelve months.

SALE OF THE GARSTON VINEYARD.—This well-known establishment, founded by Mr. Meredith, and lately the property of the Cowan's Patent Company, has again changed hands, and, as we learn, has been purchased by Mr. John Cowan, lately managing director, for a considerable sum, the Company having decided on confining their business to the London establishment.

CHISWICK HOUSE.—We hear that His Royal Highness the Prince of Wales has given up Chiswick House, the lease having expired. Mr. John Wills, of South Kensington, has been appointed to supply the floral decorations and direct the gardening at Marlborough House

THE NEW RHUBARB.

THIS, the true *Rheum officinale*, is one of the handsomest plants which has been introduced into our gardens of late years. According to the Chinese, this yields the root known to pharmacists as Canton or Russia Rhubarb. It has for some time been successfully cultivated in botanic and

long been a favourite garden plant. It is found growing wild in the neighbourhood of Mount Rhodope in Asia Minor, and on the banks of the Volga in Russia, where it goes by the names of Great Patience, Alpine Patience, or Monk's Rhubarb. The regions in which this species of Rhubarb is found are almost inaccessible, and Dr.

The New Rhubarb (*Rheum officinale*).

other gardens. The plant is a very valuable acquisition, although it is not certain that it is the only variety which furnishes good Asiatic Rhubarb. The family of Rhubarbs is one which is well known. They have, generally speaking, large palmate leaves, green above and whitish underneath, and bear yellowish-white terminal panicles of flowers. Common Rhubarb (*Rheum Rhaponticum*) has

Thorel, who has visited this part of the Asiatic continent, tells us that, so to speak, its habitat is surrounded by a range of mountains which almost blockade the approach of travellers from the south. It is on the plateaus inhabited by the Grand Lamas, which seem to be almost shut out from the rest of the world by impenetrable fastnesses, that this Rhubarb finds its home. Most of the so-called Chinese Rhu-

barb, says Dr. Thorel, comes from this part of Thibet, but a certain amount is also found in the mountains of Yunnan and Setchonan in Chinese Tartary, especially on the slopes of Mount Likiang, a mountain over 16,000 ft. high, the summit of which is covered with perpetual snow. It is said to thrive best at an altitude of 12,000 ft. above the sea-level, which is close to the snow-line in these latitudes. According to Dr. Baillon, the roots of the *Rheum officinale* grown at Bouffemont closely resemble the Rhubarb of commerce in colour and general appearance, but to the horticulturist this beautiful species is more interesting as an ornamental plant. As will be seen from the accompanying woodcut, this plant, on account of the beauty of its leaves and flowers and the boldness of its habit, is entitled to become as great a favourite in this country as it is in France. It is of luxuriant growth, easily propagated, and perfectly hardy, bearing our northern winters with the greatest impunity. It is really a grand plant for placing near the shrubbery on the turf, or for the wild garden, where its fine form would be very striking. It would be well in certain gardens to form a little colony of fine-leaved, hardy plants; in a small glade with rich soil a novel and fine effect could readily be produced by a good selection, embracing the *Ferulas*, *Heracleums*, *Rhubarbs*, *Acanthuses*, *Yuccas*, the common *Artichoke*, *Gunnera scabra*, and many other vigorous, hardy subjects that have been enumerated in *THE GARDEN* from time to time. C. W. Q.

TRIMMING TREES IN HEDGEROWS, &c.

THE scientific agriculturist may plead that wide-spreading trees and picturesque hedgerows are a bar to improved agriculture, and the profitable introduction of the steam plough requires the fields to be of regular shape and of considerable size, but in highly-cultivated districts there is often too great a tendency to trim and lop every tree into something approaching the appearance represented by the annexed sketches. The man of energy, whose sole aim and ambition in life is to make

two blades of Grass or two ears of Corn grow where only one grew before, is doubtless a very desirable man to have in any community, but unless one takes a comprehensive view of things there is a danger of falling into error. Trees, like birds and all other living things, have important functions to perform in the economy of Nature; meteorologists tell us that the rainfall of a country or district is largely influenced by the sparseness or plenitude of its tree growth; and we all know something of the value of shelter, not only

to man and beast, but to all cultivated crops; though I admit, from the artist's point of view, the grey, Moss-grown Pollard may be effective in the foreground of a tree picture, yet deformity in any shape, if often repeated, must have a depressing effect. There is, I know, abundance of room for improvement in rural districts in the arrangement and management of hedgerow timber, but that improvement should be obtained by judicious thinning, by removal of the worthless

trees, not by ruthlessly lopping off the heads and branches of all alike. At all seasons, but especially now, there is a wondrous charm in woodland scenery, and no man of taste should permit the trees bordering his field to be ruthlessly headed down or trimmed up like bare poles. Good sound timber is almost as essential as Grass or corn, and the lopped or trimmed-in trees are always worthless, except for fire-wood. Therefore, apart from the outrages often committed upon Nature by the woodman's axe, there is generally, when all things are fairly considered, little or no gain derived from the practice. E. HOBDAY.

HALL PLACE, TONBRIDGE.

THIS, the residence of Samuel Morley, Esq., M.P., adjoins the village of Leigh, near Tonbridge. The mansion, a modern erection, is situated on a gentle eminence, and surrounded by a well-wooded deer park. When the estate came into the hands of the present owner, the old mansion was taken down, and the present one built on a new and more elevated site; the original pleasure grounds and kitchen gardens were, however, retained, and much enlarged. The surplus material from the foundations of the mansion was formed into a mound and planted. By means of this mound and plantation, the walls and other erections connected with the kitchen garden are wholly concealed from the grounds on the private front of the house. On this mound is built a brick tank capable of containing over 1000 gallons of water, supplied from a well in the valley. The water is forced upwards through a line of pipes about half a mile in length by means of the water power of an adjoining stream and the use of a turbine wheel. The elevation of the tank—about 30 ft. above the average level of the ground—is found to supply ample power to work hydrants, with which the gardens are everywhere provided. On the north or carriage entrance front, the lawn slopes towards a lake about 13 acres in extent, formed when the mansion was built. This lake occupies a natural valley in the centre of the deer park, and beyond, on elevated ground, is a considerable breadth of woodland, consisting chiefly of Oak, Elm, Beech, and Lime. During the progress of improvement, a considerable number of large Horse Chestnut and other deciduous trees were successfully transplanted when in full leaf, but of these we hope shortly to give more detailed particulars. Many fine and interesting trees are scattered about the grounds, such as Cedars, *Taxodiums*, and various Conifers, including an example of *Pinus insignis*, 40 feet high. H.

HALL PLACE, TONBRIDGE (Designed by Mr. Manscock).

- 1. Kitchen Garden and forcing-houses.
- 2. Terrace.
- 3. Open lawn.
- 4. Reservoir.
- 5. Stables.
- 6. Forecourt.
- 7. Parterre garden.
- 8. Wilderness.
- 9. Lawn on carriage entrance.
- 10, 11, and 12. Bridges.
- 13. Boat-house.
- 14. Park grounds.
- 15. Grass walk.

PENTSTEMONS AND THEIR CULTURE.

AMONGST Pentstemons we have a wonderful wealth of colour varying from pure white to glowing scarlet, the intermediate shades consisting of pink, rose, purple, carmine, and purplish-lilac. If good plants of Pentstemons be put out by the end of April; they will commence to bloom about the middle of June, and will continue to yield a succession of flowers until winter sets in. They require a deep, moderately rich soil, and a position fully exposed to the sun. They can be raised from seed any time between March and August; but those raised early in spring will bloom the same year, and those sown after midsummer will not flower until the following season. The seed should either be sown in pans in light, fine soil, and placed in a close, warm frame, or on a gentle hotbed. As soon as the plants are large enough to handle, they should be pricked out on a bed of rich soil, encouraged to grow, and planted in their blooming quarters as soon as possible. When raised in the autumn, they should be pricked out into pots or boxes, and wintered in a cold frame, or they may be wintered on a sheltered border, and protected during severe weather with mats or Spruce branches. The best way, however, is to procure a stock of named sorts, and perpetuate them from year to year by means of cuttings, as is done in the case of Verbenas and Zonal Pelargoniums; for, out of say a hundred seedlings, perhaps not more than half-a-dozen will be worth saving. When a stock of named sorts is obtained, young plants can be struck in the autumn, and the old ones destroyed when a sufficient quantity of cuttings has been obtained. There is no difficulty as regards propagating Pentstemons; on the contrary, they may be increased and grown in every respect the same as common shrubby Calceolarias. Towards autumn the plants throw up numerous side shoots, and as many of these as are required may be taken off and struck under hand-lights or in cold frames. During winter they should be protected by a cold frame, and planted out early in April in a deep soil and in a sunny situation. The following are good sorts and well worth growing, viz.:—Black Knight, Bridesmaid, Agnes Laing, Grandis, Snowdrop, Henry King, Painted Lady, Stanstead Surprise, Olio, Victor Hugo, The Emperor, Queen Victoria, Madame Patey, James Rothschild, Maria Field, Mrs. A. Sterry, Albert Jardieu, Colin Bell, Duc de Lorraine Eclat, Flower of the Day, George Sand, Sarpasse, and Souvenir, de St. Paul. K. R.

GROWING FERNS IN LOAM.

SOME time ago we pointed out the propriety of using more loam and less peat for Ferns, and said we intended to use loam more generally in future, and we have now to record farther experience in the matter. Early in February we potted about 300 plants, consisting of a general collection of stove Ferns, in a compost of loam and leaf-mould and a very little peat, one-eighth perhaps, or less; in fact, all the strong-growing sorts of any kind were potted in the compost used for the stove plants, and for the more delicate *Adiantums* more leaf-mould and sand were added, but still leaving the staple pretty loamy. The plants are now beginning to grow away pretty freely, and, saving the *Gymnogrammas*, which do not show much difference as yet, all the specimens may be said to exhibit a marked increase of vigour, particularly the Maiden-hair kinds, which are producing fronds freely at least three times as large as they did in a compost consisting principally of peat, and the colour of the foliage is all that could be desired. The plants were looser in taking to their shift than usual after being potted, and we were beginning to doubt the advantages of loam; but, now that the roots have got hold, they are sending their fronds up clear of the old foliage with unusual vigour. No liquid manure has been given any of the plants as yet. We are not here speaking of the advantages or disadvantages of having large plants; but it is good to know what sort of compost suits the Fern best. With us the loam will be an advantage, for we need large plants in small pots for furnishing. Our loam, we should state, is of the heaviest kind, not to be actually clayey, for which allowance must be made; some of the brown turfy loams that we have seen would probably be better unadulterated for Ferns. At all events, we have no hesitation in saying that for the general run of stove and greenhouse Ferns peat is entirely unnecessary, and too hungry a compost to use in large proportions. A well-known London nurseryman, who called upon us when we were having the plants potted, predicted disappointment by using the loam, particularly of the Maiden-hair varieties, but his prediction has been falsified.—“Field.”

Large-leaved Caladiums.—I find that these do best when grown on without shifting—that is, when put at the first into the pots in which they are to remain. Amongst a number of plants treated in this way we have at the present time a specimen of *C.*

esculentum, which was potted early in March in a 10-in. pot. It has now fine healthy leaves, each larger than its predecessor—the first leaf, being 2 ft. 9 in. in depth, and proportionately broad and the last formed, only unfolded a day or two, 3 ft. deep, and over 2 ft. across, and it is still growing. Whether the plant will now flower or produce another leaf still larger remains to be seen; but had it been shifted into a large pot, no doubt the leaves would have been checked in their growth. I once had a plant of the same kind, which was treated in the same way (one bulb being potted at the beginning in a 14-in. pot), that had leaves close upon 5 ft. deep. When placed on a man's back it completely covered it, and it was so broad that it could be folded round him, looking very much like a coat with one tail.—J. S. W.

Gilbert's A. F. Barron Melon.—After a second season's trial I can strongly recommend this as a late summer Melon, especially where facilities for supplying bottom-heat are limited. In many places early Melons are not cared for, but a really good Melon in August is always everywhere appreciated. Those who are clearing out pits that have been used for bedding plants need not wait to raise the young Melon plants in pots, unless they have the plants ready, as, if the seeds be planted in the hills of warm soil where they are intended to remain, the plants will come up quickly and do well. It is perhaps as well to plant three or four seeds round the hill of soil and finally thin out to two, selecting of course the best.—E. HODDAY.

Sarracenia at Glasnevin.—To any one who takes an interest in quaint forms and the anomalous development of vegetable life, the North American Pitcher-plants (*Sarracenia*) just now in flower in the Victoria-house at Glasnevin would be quite a study. On a shelf stand, in single file, some three dozen or more healthy specimens of these singular plants, comprising, we should think, all the species in cultivation. Amongst them are several specimens of *Sarracenia purpurea*; also examples of *S. flava*, with its pale greenish-yellow flowers, in striking contrast with those of the preceding. Then we have Dr. Moore's hybrid *S. Mooreana*, perhaps the most interesting of the series, on account of its stately habit and striking resemblance to both its parents (*S. flava* and *S. Drummondii*). Then come *S. rubra*, *S. variolaris*, and though last, far from being the least interesting, the Parrot-like *Sarracenia*, *S. psittacina*, with its singular anaphoræ, not standing up like those of the others, but radiating from the crown, like the spokes of a wheel, and with perfect regularity, and resting on the surface of the pot. The Glasnevin specimen has three flower-scapes, but the flowers were not quite expanded when we (“*Irish Farmers' Gazette*”) saw them last week. Taking it all in all, it would be difficult to meet elsewhere with a series of these singular productions so extensive and varied as they are here. It must not be inferred from the mention of the Victoria-house that they are grown at Glasnevin in a high temperature. No such thing. From the time the *Victoria regia* dies down in autumn till about the present time there is no fire-heat whatever, or, at all events, very little, applied to this house.

Hybrid Foxgloves.—I can endorse all “A. D.” says (see p. 111) about Foxgloves. I was the raiser of *Digitalis gloxiniaeflora*, and had many years ago far more beautiful varieties than any I have seen for some years. I have hybrids between *Digitalis purpurea* and *D. grandiflora* which will be very interesting and beautiful, combining the perennial character of *D. grandiflora* with the colours of both parents. These hybrids seed freely, but are very shy in vegetating, and I may safely say that no two plants are alike. Foxgloves need fear no rivals, either in the wild garden, the woods, or the backs of flower borders. I have bloomed them in pots in cold greenhouses, and it is in these they may be operated upon by the hybridizer. They will grow almost anywhere, and are still capable of vast improvement as regards the shape of the flowers. I once had one which bore very large bells, so open as to show fully a beautifully spotted interior on a white ground; this came true from seeds. All the hybrids between *Digitalis purpurea* and *grandiflora*, *D. lutea*, or *parviflora*, will be perennial in habit, and choice forms may be easily propagated by means of cuttings, which seem to thrive as well as seedlings when once they get a start.—W. ELLIOTT, *Stapleford Hall, near Nottingham.*

Fungus in Hotbeds.—Can any of your readers give me any information as to the cause of the growth of a fungus in a hotbed, which I made some weeks since for the purpose of starting *Achimenes*, *Gloxinas*, &c., consisting of four loads of good stable manure? The fungus in question grows very rapidly, and entirely blackens the leaves of the plants, the soil, and the pots, and though I dig up a great deal of it almost daily, still I find that it affects the growth of the plants very considerably. I have just planted out my *Cucumber* plants in the frame, but I fear they will never produce any fruit. I have made hotbeds for several years, but have never met with a fungus of this nature before. I shall be glad to know if there be any means of overcoming it short of destroying the bed altogether.—J. B.

THE FLOWER GARDEN.

A NOBLE HARDY EVERGREEN BAMBOO.

WE have at various times called attention in THE GARDEN to the merits of this very distinct Bamboo, which thrives freely in various parts of the southern counties. It does not, like various other valuable subjects of a like nature, require a warm mild or seashore climate, as we have noticed it thriving vigorously in the home counties, and even doing fairly well in the smoke in the Duke of Buccleuch's garden at Montagu House. We, however, had no idea of its full value till the past winter, throughout which several finely grown bushes of it have been the finest evergreen ornaments of the Parc Moncean; one of these was drawn for us by Mr. Godard, in January, and from the sketch the accompanying engraving was made. The plants were about 10 ft. high, of very free growth, and well furnished, and the leaves, which are considerably broader and larger than those of the other hardy Bamboos, are of a fine green. It would be difficult to find more graceful ornaments for the flower-garden or pleasure-ground.

IMPORTING NEW WATER LILIES.

IN a recent number of the "Botanische Zeitung," Dr. R. Caspary describes a new African Water Lily, which he names *Nymphaea zanzibariensis*. But it is not so much for the sake of the new species that we refer to it here, as for the opportunity of repeating his instructions respecting the best way of transmitting seeds of these beautiful aquatics for long distances, to preserve their vitality. For many years Dr. Caspary has made the *Nymphaeaceae*, or rather the genus *Nymphaea*, his special study, and it has been his object to cultivate as many forms as possible in order to test the value of characters which can only be imperfectly seen and appreciated in dried specimens. In his endeavours to introduce different species, he has gained some experience in the conveyance of their seeds, which may prove useful to some of our readers. Sent dry from the tropics, and exposed to great heat on the journey, they are almost certain to lose the power of germinating; and sent in water they are quite certain to rot. Dr. Caspary lost many valuable consignments from various parts of the world before he thought of the means described below. True, it is only in part new, and no more than the adaptation of an old idea. It is simply drying the seeds quickly after collecting, and then squeezing them into moist loam or clay in a tin box. When the clay or loam is dry the box is soldered down air-tight. In this way the seeds may be sent for any distance without losing their vitality. Dr. Caspary has also frequently received good seeds sent from very distant countries, which had been embedded in moistened powdered charcoal, and otherwise treated as with clay or loam. J. M. Hildebrandt, who discovered and introduced seeds of the new species described by Caspary, used white carbonate of lime (chalk), and when the seeds arrived they were in a solid mass of this substance. They were at once put into a basin of water, which was kept at a temperature of 22° R. (81°·5 Fabr.). They laid dormant for two months, and then germinated in numbers. Many plants were safely wintered in 1874-5, and in the course of 1875 seven strong plants in large bowls produced flowers. In 1876 one tuber was planted in a box 4 ft. square, and this was sunk in a tank 23 ft. in diameter in a house in the Botanic Garden at Königsberg. Treated thus it developed into a fine plant

Rambusa Metake (10 ft. high).

and bore flowers up to 9 in. in diameter, and always two or three together; and the leaves were 2 ft. in length. It proved to be a new species; and, more than this, the most beautiful of the genus—eclipsing even *N. gigantea*. The sepals are of a deep green, and destitute of spots on the outside, with a broad crimson margin, and of a deep violet-crimson within; petals deep blue, with a whitish spot at the base, the outer ones crimson near the base; and the outer filaments yellow. Dr. Caspary concludes with an appeal to those in a position to do so, to send him seeds of African species not in cultivation, especially the forms found in Lower Egypt in the inundated rice fields; and he is willing to pay 30s. or 50s., or more, for good seeds of a species. He would be glad to get the *N. cœrulea albiflora* of Sieber. Such fruits should be selected from which the parts of the flower have rotted away, and placed in a moist box. In the course of three or four days those containing mature seeds will have burst, and the seeds should then be placed in warm water to allow the coil to rot off, which, according to the "Gardeners' Chronicle," will take place in a day or two. The seeds which have sunk to the bottom should then be taken out, slightly dried, and packed in the manner described above.

Growing the Fragrant Water Lily.—If lovers of flowers only knew how easily the fragrant white Water Lily (*Nymphaea odorata*) could be cultivated, we are quite sure that it would be grown

far more extensively than many other less fragrant and beautiful flowers that take more time and trouble to cultivate. This Lily once planted in a pond or small stream that does not entirely dry up in summer, will need no further care, and will increase from year to year. People who have not the facilities for growing it in a pond or stream, can have their Lily gardens in tubs and aquariums where they can admire and gather this most fragrant and beautiful flower that grows on land or water. Take, for instance, a strong barrel, saw it in two, fill this one-third full with fine black garden soil, or meadow mud if handy, plant the roots in this mixture, covering them 2 in. deep, add water gently so as not to disturb the roots until the tub is full. This is all the care needed—always keep the tub full of water. Set this on a brick or board platform

in any place you desire. The tubs with their contents should be placed in a cellar during the winter, kept from frost, and not allowed to entirely dry up. For ponds and streams, tie a stone close to the roots, large enough to sink them, and drop this into the pond or stream where you wish them to grow. For aquariums put in 5 in. of fine black loam, cover the roots 1 in. deep in this, and sift on the loam fine sand enough to entirely cover it.—B. MANN, in "Gardeners' Monthly." [This is the American hardy white Water Lily, not ours. We hope some readers of THE GARDEN have already established it. We believe it is obtainable in some nurseries.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Veronica Halkei at Glasnevin.—This is stated (see p. 420) to be a valuable greenhouse plant. It is quite a hardy shrub, or nearly so, at Glasnevin, where it is planted at the foot of a wall, and where several plants of it in aspects north and south are now flowering profusely.—A. BALFE, 28, Westland Row, Dublin.

Ivy-leaved Pelargonium Nemesis.—This beautiful variety has brilliant magenta or rosy-crimson flowers. Its dwarf, compact growth and free-flowering habit render it suitable for forming a bed in the flower garden. It is also attractive as a basket or vase plant for conservatory or terrace decoration during the summer months. The first flower-buds open with a bright carmine tint, and gradually change to magenta. In its respective colour it is the finest yet offered for summer groups or pot culture.—E. G. H.

THE KITCHEN GARDEN.

BROCCOLI AND ITS CULTURE.

THIS is one of those vegetables the culture of which needs more than ordinary care, and the keeping up a supply from the time when Cauliflowers are over until the following summer requires some practical experience. As a rule, in private establishments Broccoli is cut when about one-half its full size—therefore the great aim should be, not the production of gigantic heads, but a constant succession of firm compact Broccoli of medium size. Some choose a few good kinds and make successional sowings, whilst others select a number of varieties that will naturally succeed each other, although they may all be sown and planted out at the same time. This is doubtless the best plan when the ground intended to be occupied with Broccoli can be all sowed and got ready at one time, but it frequently happens in establishments in which the demand for vegetables is greater than the ground allotted for their culture can supply, that part only has to be planted as the ground becomes vacant. Many people plant Broccoli between rows of Potatoes, and where the ground is limited, and the kinds of Potatoes grown are dwarf and planted a good distance apart, it is doubtless a good system. Where this plan is adopted, the very hardest pieces of land should be selected for the Broccoli; for the firmer the soil, the better they stand the severity of the winter. They also come into use more regularly in rotation in their several seasons, and form larger and closer hearts than if planted in less compact soil. Supposing two rows of early or second early Potatoes are planted from 20 in. to 24 in. apart, there should be two rows of Potatoes between every two rows of the Broccoli, which will place the rows of Broccoli about 3½ ft. or 4 ft. apart, and this distance is not too much, as it gives both crops plenty of room to develop themselves. The Potato haulm should be turned from the Broccoli to the unoccupied space between each two rows of Potatoes. It is now a very common practice to plant many of the Brassica tribe with a crowbar; the holes are filled in with fine soil, and the ground afterwards thoroughly soaked with water.

Sowing and Planting.

Though June is the month in which most cultivators try to get their plantations of Broccoli finished, yet it is frequently July before the work is done. Plants put in in August will make good heads, but the sooner the planting is done after the middle of June the better, though planting early ensures the finest plants and largest heads. The time of sowing or planting does not materially affect the plants as regards the time they come in use. The usual time for sowing Broccoli varies from February till April according to different localities; as a rule from the end of March to the middle of April is the best time if the weather be genial. The best manner of sowing is in shallow drills about 6 in. apart, and if the seed can be depended upon as being good, it should be sown thinly. The whole sowing may be made at the same time, for convenience sake; and, by planting a good many varieties a regular supply throughout winter and spring may be ensured when the winters are reasonably mild—for it is certain that no practice as to time of sowing or planting will ensure the heads forming at a certain time, if during winter we have protracted periods of frost or cold, during which all growth is at a standstill. Plants from sowings made early in April as recommended will under favourable circumstances be large enough for pricking out by the middle of May; they should have a moderately rich open border assigned to them where they can have the benefit of the sun to keep them strong and sturdy. Young plants should be pricked out 7 in. or 8 in. apart, and by the beginning of June the ground should be prepared and finally planted out, choosing a showery time if possible, otherwise recourse must be had to the watering pot. Many people never transplant their Brassicas previous to their final planting, but where time can be spared it is much the best practice, as the plants grow larger and stronger, and are better able to resist the attacks of slugs, snails, &c., than small plants put out direct from the seed-bed.

Though it is by no means an unusual thing to see little heads of Broccoli in cottagers' gardens where the soil is seldom turned over more than a spade's depth, and not over liberally manured, yet the plant likes a deep and rich soil. If practicable, the ground should be trenched two or three spades deep, or at least double-digged. When there is not time for doing either of these, the ground must be dug over a spade deep only, taking care to break the soil up thoroughly, as deeply as a good spade will do it, and working in some well-decayed manure at the same time. Planting should be proceeded with as soon as the digging is finished. If the planting be done in June or July, from 2½ ft. to 3 ft. must be allowed between the plants; if deferred till August they need not be allowed so much room. If the weather be dry, the seed-bed, or that from which the plants are taken, should be watered well the night before to soften the soil. The holes to receive the plants should always be made sufficiently large to admit of them being easily put in without breaking their roots. "Buttoned" and stunted plants are in many cases caused by bad planting. They are put in with broken and mutilated roots; and those that have a tap-root often have it bent double in getting it into the hole, and, instead of the point being at the bottom of the hole, it will be sticking up above the surface. No one should wait for wet weather to commence Broccoli planting, it is better to get it done at once, watering copiously once or twice, after which they will thrive till rain comes. When the plants are fairly established, and have grown a little, they must be earthed up with a hoe, more to prevent the wind from twisting them about than anything else.

Soil and Manure.

Broccoli thrives best in a deep loamy soil, well drained, but it is not very particular in this respect, and will produce fine heads in any well-enriched soil of which the staple is loam. In old garden soils in which humus has accumulated, it is often attacked with the grub or maggot, which causes "clubbing." In such cases lime may be applied with great advantage, or burnt clay and fresh loam, if it can be afforded. The ground should be trenched two or three spades deep previous to planting, and the manure, if rotted, well incorporated with the soil, or if rank, buried in the bottom of the trench. If trenching cannot be done, then Broccoli should follow some other crop, such as Potatoes or Onions, or any crop not belonging to the Cruciferae or tap-rooted section, such as Carrots, Turnips, or Beet, and the ground should be dug as deeply as a good spade will go, and well manured. Where the soil in which Broccoli is to be planted is naturally of a light character, if moderately rich, it should not be dug, but made as firm as possible round the plants. The best kind of manure for Broccoli is undoubtedly well-rotted stable manure, with a sprinkling of soot added to destroy worms. Watering is seldom necessary after the plants have become well established.

Heeling-in Broccoli.

As regards the heeling-in or laying of Broccoli, there has been much dispute; many growers think it a great advantage, whilst others think it at least unnecessary. That it has merits and demerits, there can be no doubt; but, as a rule, private growers are in favour of the practice of laying, their object being—firstly, to check growth, as they believe that disturbing a considerable portion of the roots has the effect of hardening and solidifying the whole plant, and of enabling it better to withstand severe weather; secondly, to place the plants in such a position that the sun, during alternate frost and thaw, will not get to the hearts, as these suffer more from frost in the night after being thawed by the sun in the day than when continuously frozen. For this reason the heads are laid so as to face the north or west. To accomplish this, if the rows run east and west, they commence on the north side of the first row, and take out a spit of soil just the width of the spade, so as to form a trench within 2 in. or 3 in. of the stems of the plants, laying the soil, as the work proceeds, on the side away from the row. This necessarily removes the soil from the roots, no more of which is to be broken off than can be avoided. All the plants in the row are then regularly bent over until their heads rest on the ridge of soil taken out

of the trench. When this is done, commence with the next row, taking the soil out so as to form a similar trench, and laying it in a ridge upon the stems of the row of plants bent over, so as to cover them right up to their bottom leaves; and, in this way, proceed until the whole is completed. If the rows stand north and south, the work is begun on the west side. By this process, as will be seen, all the roots on one side of each row, and a portion of those on the other, are considerably disturbed. This causes the leaves to flag a good deal for a week or two, which has the desired effect of checking growth. The more vigorous and large the plants, the greater the supposed necessity for thus preparing them for winter. In light soils, where they can be got up without much mutilation of the roots, should it be desirable to get the ground ready for some other crop before the Broccoli is off in spring, they may be taken up altogether and laid in some more convenient place, lifting them, as far as possible, with all their roots intact. Where time can be spared, I believe this to be a good system, as I have frequently noticed that where Broccoli is properly managed in this way, it is only during exceptionally severe winters that it gets destroyed, and the drier the land is the more frost the plants will bear without injury. The length of time during which this vegetable affords a succession, at a period of the year when there does not exist much variety, makes it worth while to do all that is possible to preserve it. Fortunately, however, severe injury to the Broccoli crop is the exception rather than the rule, and is quite as likely to be the consequence of imperfectly-ripened stems as of hard weather. The immense breadth of Broccoli grown for the London markets renders any process of heeling-in almost impossible. A few hundreds of plants might be so managed; but when hundreds of thousands are in question, the case is different. There are very large breadths of Broccoli grown in Kent, the consignments in some seasons averaging as much as 12,000 heads per day; in some cases it is probable that there were a quarter of a million plants in a piece, and one scarcely sees a failure anywhere. We sometimes see near the Shepperton station on the Thames Valley Railway, some splendid breadths of Broccoli as much as 18 or 20 acres in extent. Such large plots as these show that market growers cannot afford to "heel-in" their crops of this esculent; and yet they are in every way excellent, and failures seldom occur.

Varieties.

There have been many new varieties lately added to our list of Broccoli, many of which are of especial merit, but still it is not advisable to discard old and tried varieties to make place for those of less certain value. There are many varieties that are new in name only, and often when we think we are selecting a dozen kinds, we are in reality only selecting a few bearing several names. Then again some kinds will succeed better in some localities than in others, according as the soil or situation is suited to them. Amongst the many good kinds of Broccoli for succession the following may be mentioned as some of the best, Grange's Early White, Adams' Early White, Snow's Winter White (this is perhaps the best in cultivation), Early White Cape, and Osborn's Winter White: the foregoing are early and midsummer kinds. The best late kinds are Chappell's Cream, Dilcock's Bride, Wilcove's Late White, and Cattell's Eclipse, the latter being the best late variety in cultivation and will last out in the spring until Cauliflower is plentiful. The Sulphur, Purple Sprouting, and Late Purple are all hardy kinds and very useful, but as a rule their colour is objected to in private establishments. Among new varieties of Broccoli lately sent out the two following are highly recommended, as being great acquisitions to all growers of this valuable vegetable:—One variety was sent out by Messrs. Watts, of Northampton, under the name of Excelsior; and the other by Mr. Cooling, of Bath, under the name of Matchless. They are both midseason sorts, coming into use from the middle of March to middle of April. Both kinds are thoroughly protected by their leaves, and may be cut snow-white before the heads are exposed to the air; while their flavour, when cooked, is everything that can be desired in a Broccoli. When the heads come in too fast, as in other varieties the leaves can be tied over them to preserve their

colour; and, either for growing for market purposes or for private use, these two sorts are said to be the very best in their season. Another new variety, sold under the name of The Leamington Broccoli, has recently been certificated by the Royal Horticultural Society, and is said to possess good qualities. S.

CHICORY AS A SALAD.

THE Chicory is a comparatively little known plant in this country, but it deserves extensive cultivation as a winter salad on account of its wholesomeness and easy culture. When Lettuces and other things are scarce, there is never any difficulty in having plenty of Chicory, and it is to a large extent a substitute for both Lettuce and Endive. The latter are apt to be lost during the winter from various causes; but the Chicory is a hardy root, and if sown in time the roots will be strong, and, like Seakale, may be taken up and forced when wanted. There are summer varieties of the Chicory, too, it should be mentioned, but they are wholly unknown in English gardens, and are only noticed in gardening works. In "Robinson's Parks, Promenades, and Gardens of Paris" they are more particularly referred to, and we are told that "the Chicorée Fine d'Été and C. Rouennaise are the best summer kinds; C. de Meaux is the large one, used in a cooked state, as we use Spinach; and C. de la Passion is a large variety, passing through the winter well without protection. The Scarolle, for winter or autumn salad, is a really noble kind of Endive, with smooth leaves, a vigorous constitution, fine flavour, and every good quality that such a plant should possess; and yet it is not at all sufficiently known or grown with us. The best kind is the Ronde or Verte, but the Blonde is also good. Of the wild Chicory there is an improved variety, Chicorée Améliorée, which forms little heads 4 in. or so in diameter in early spring, and is then very acceptable in a salad-loving country. By putting a cloche over stools of this variety, these little heads may be had all the winter. To blanch them slightly is an improvement; but this variety must on no account be employed to yield the Barbe, that popular Parisian winter salad. That is simply the common Chicory." It is of the culture of the last-named variety we intend to speak here, but we have given the above extract concerning the other kinds, as being the only particularised account of them we know of in any English work on gardening. When grown for blanching, common Chicory is usually sown from now till the end of June; if sown sooner, it goes to seed. The object of the cultivator should be to get good strong roots, capable of producing a good quantity of leaves when they come to be forced. The plant is not particular as to situation, but it should have a rather light and moderately rich and deep soil. Being a tap-rooter like the Carrot, it sends its Carrot-shaped roots straight down, and when it can do so freely, the plants are always much stronger. The ground should be deeply dug with a spade or fork, or trenched (if it has not been done in the winter time), and the seed sown at the same time in drills not less than 15 in. apart; and when they can be handled well, the seedlings should be thinned out to 1 ft. asunder in the rows. After this, the only attention they will require will be hoeing between the rows and watering in dry weather till November or December, when the plants will have shed their leaves, and be ready to take up for forcing. The forcing of the roots is comparatively an easy matter, which entails little or no preparation. When the leaves have decayed, a number of roots should be taken up and laid in soil, in some cold shed or other structure where they will not be frozen, and from this store they can be removed in batches for forcing as wanted. This is merely a precaution, be it understood, in case of severe frost or snow setting in and preventing them being lifted from the bed, where the main lot should be allowed to remain. The quantity of roots to be forced at a time will depend upon the demand for the salad. Fifty plants are sufficient at a time for a considerable establishment, and a batch may be put into heat about every three weeks; but for a small family as many roots as can be put in a 12-in. pot will be sufficient. Whether the roots are forced in a bed, or in pots or boxes, they should be buried up to within an inch of their crowns in light soil of any kind, watered, and placed in a temperature of from 50° to 60°, and be kept in the dark. If a dark shed or cellar be not available, the crowns may be covered with an inverted flower pot or box, which will do quite as well; in this way Chicory is sometimes forced in a kitchen. The leaves soon push, and they should be cut when they are young and tender, and always just before they are required for salad, for which purpose they are prepared like Lettuce or Endive. The roots will push a second and even a third time after being cut, but the growth is weaker every time, and the better plan will be to introduce a succession of fresh roots before the previous supply becomes exhausted. C.

THE FRUIT GARDEN.

A "FRONT" GARDEN OF FRUIT TREES.

The accompanying illustration shows a type of fruit garden common enough in and near Paris, and which well deserves the attention of all interested in the improvement of small properties. A mere spot of ground is planted with carefully selected and choice fruit trees well trained, and the result is, even from an ornamental point of view, better than it often is where subjects are planted that have beauty only to recommend them. Our view is from a sketch taken in winter by M. François Courtin, of a small garden facing the street leading from Vincennes to Montreuil. Beneath the trees Pansies, Pinks, and other hardy flowers grow: the presence of the trees does not prevent the little garden being made gay with flowers. In winter, the graceful pyramidal Pear trees and well and simply-formed Peach and Plum trees against the walls certainly look better than the contents often presented by little gardens arranged with another aim. In spring there is the beauty of fruit-tree blossoms, and in autumn the crown of trees—beautiful and good fruit. The art of the engraver, even in its best form, can give but a suggestion of such a garden, but probably this will show how desirable it is to make, more than ever, full use of our opportunities of planting fruit trees in small gardens. The market distribution of the good things produced by our fruit growers is so very imperfect that it behoves the owner of even the smallest garden to secure as far as possible his own supply. We may even say that much of the monotonous entanglement now known as shrubbery might well be exchanged in small gardens for well-grown and well-chosen fruit trees.

A Front Garden of Fruit Trees.

Covering Early Vine Borders.

As Mr. Baines does not seem disposed to discuss the real question involved in this matter, and upon which the practice he recommends really hinges, I have little more to add. All that I contend for is that in Vine culture, the root and top temperatures should bear a reasonable proportion to each other, and what that proportion should be I have already stated; and were I to advise generally, I should prefer laying down some such rule to recommending a particular practice that was most assuredly not applicable in all cases, and which in some cases might lead to disastrous results. I further believe that I am supported in my views by most authorities on Vine growing, while logically I do not see that they can be disputed. Mr. Baines' own practice in everything, I think, but Vines, is also in my favour, and it seems he would with some subjects go in the contrary direction even much farther than I should. At p. 275 of THE GARDEN for April, Mr. Baines tacitly recommends a bottom-heat for Cucumbers of 85° or 90°, which is perhaps as far above the mean temperature necessary for these plants, as a Vine-border, treated as he recommends, would be below the mean temperature of the Vinery—all of which is very inconsistent teaching. Such a temperature is, however, neither necessary nor desirable for the Cucumber, even in the warmest season, let alone in the month of April, when the maximum heat can seldom be got up to the above figure. Cucumbers can be grown successfully all the year round, and sometimes without changing the plants, in a bottom-heat of from 70° to 75°, figures which are much better not exceeded during the cold season at least. Cucumbers pushed on by the mere force of a high bottom-heat, irrespective of the amount of light and the top temperature, are never either healthy or long-lived.—J. SIMSON.

Planting Orchards.—Too often when a new Orchard is planted to take the place of a worn-out one, rough holes are made where the old trees were taken out, and the plants are put in just as one would a post to hold a gate. In other cases, when old trees begin to fail, they are cut over and grafted with other kinds; but the roots dying (which is the real cause of failure) leaves these grafted branches a thicket of dead and cankered sticks. Though cattle and sheep are often put to graze under the shade of Orchard trees, with the view of producing something more than the Orchard supplies, the returns are small compared with what they would be were the pasture having its wants properly looked to, or the trees cultivated with a minimum of skill. It is not correct to suppose that because certain counties have a name for fine fruits that much skill is displayed in the management of the trees. In most cases they are left to themselves, and become so crowded that crops are had merely from the outer margins. This wasteful and negligent system is not only confined to the eastern and southern counties, which have long had a reputation for fine fruit—Kent especially—but in Somerset, Wilts, Worcester, and other counties, large tracts of valuable land will be found covered with neglected Orchards, wasting space which ought to supply either abundance of fruit or valuable farm-produce. But both being attempted on the same land, and neither the one nor

the other giving satisfaction, it is clear that immense waste is the result. Improvements are, however, taking place in fruit tree management in some districts, not only by better sorts superseding worthless kinds, but by a proper system of planting and thinning being carefully followed out. In Worcestershire especially cultivators plant thickly at first; and as the trees require more room, those which can best be spared are lifted and either sold or transplanted into fresh Orchards; kinds, too, are grown which fruit freely, and which are known to succeed in the district.—M. T.

Calville Blanche Apple.

—This Apple grown as cordons on the French Donein stock, bears abundantly on the bottom of a south wall where a little protection can be given to the blossoms in frosty springs; but to see it in all its beauty and size, it is best grown in pots in an Orchard-house. When well grown and ripened, it is one of the best varieties which we possess; and in February, March, and April no other Apple proves so grateful, espe-

cially to invalids. When well grown, it is too valuable for baking purposes, but in some seasons here, where the fruit has been grown on espaliers, and not ripened well, it has been used in the kitchen, and found to be the most delicious of all sauce Apples. There is another Apple which, when grown in pots, possesses the greatest beauty, namely, Cox's Pomona. A little tree of this placed on the dinner-table, with a dozen or two of its highly-coloured fruit, is a worthy companion to the yellow-fruited Calville. When the Pomona is on the Paradise stock, and grown in pots either in the orchard or in the open air, with plenty of air and sun-heat, it never fails to acquire that brilliant red colour which is so attractive in Apples.—W. TILFERY, *Wellbeck*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Peach Culture at Niagara.—A correspondent of the "Country Gentleman" has been giving some interesting information about Peach culture along the Niagara River, and thus speaks of the Peach:—"Most of the Peach orchards in this region are in full vigour. They bore good crops for the past five years in succession. This year, from some unknown cause, there are very few. It is estimated that the Peach orchards of the township of Niagara contain 40,000 trees, and it is likely to become noted as one of the best Peach regions of the State. The best Peach region appears to be confined to a breadth of a mile or two along the river. Farther inland this crop has not been so successful, until we reach the neighbourhood of Lockport.

THE NEPENTHES OR PITCHER-PLANTS.

THE *Nepenthes* rank amongst the most singular and interesting subjects belonging to the vegetable kingdom; indeed, they are singular enough to form the sole genus of the Order of *Nepenthaceæ*. They never fail to attract the attention and excite the curiosity of the most careless beholder. There are about twenty species known to botanists, and they are chiefly natives of Sumatra, Borneo, and the adjacent islands of the Indian Archipelago. One is found in Ceylon, two in Mada-

plants are found more difficult to cultivate successfully than they are, and which at the same time do not impart nearly so much interest to a selection of plants. I would, therefore, strongly urge all who possess a house for stove plants to include at least half-a-dozen of the most striking Pitcher-plants, and I will vouch for it that, with nothing more than ordinary attention, they will prove to be of great interest. They, more than most plants, give character to any collection, however extensive or however select.

Nepenthes Chelsoni (a hybrid raised by Messrs. Veitch between *N. Dominii* and *N. Hookeriana*).

gascar, and a few in Continental Asia. A good many hybrid *Nepenthes* have been raised in this country, chiefly, if not exclusively, in the nursery establishment of Messrs. Veitch & Son, under the manipulation of their celebrated hybridist, Mr. Dominy. It is a common and erroneous idea that the *Nepenthes* are very difficult plants to propagate and cultivate. This is much to be regretted, for it has very greatly prevented their more general cultivation. I know of no reason why a few *Nepenthes* should not form conspicuous objects wherever there is an ordinary plant stove, in which generally many

Various methods have been recommended for the successful propagation of *Nepenthes*. Some of these methods are tedious, and others are complicated, and, as a rule, uncertain in proportion as they are complicated. Some recommend and practise the layering of young shoots in spar, fine gravel, or coarse sand. Others strike them from cuttings by preparing a bed of chopped Sphagnum, on which small empty inverted flower pots are set, and the cuttings are put down through the hole in the bottom of the pot, allowing their base to rest on the Sphagnum. The simplest, quickest, and most certain way

with which I am acquainted is to put fresh sawdust to the depth of 6 in. in the warmest part of the propagating pit where there is a bottom-heat of from 95° to 100°; and after making the sawdust moderately firm, to insert the cuttings, and cover them with a glass case or large bell-glasses. The secret—if secret it can be called—of success, is to keep the sawdust constantly warm, wet, and close. In this way I strike nearly all sorts of *Nepenthes* cuttings, with not 5 per cent. of failures, and find that they are ready to pot up well-rooted in about six weeks after they are inserted. The striking of *Nepenthes* in this way may be regarded as one of the most simple and certain of all gardening operations. In selecting the cuttings preference should be given to those which are moderately firm, somewhat slender, and short-jointed. These make the best foundation for compact, bushy plants. I have, however, made up long growth of such as *N. Rafflesiana*, *distillatoria*, and others, into cuttings, with one or two joints and a leaf or two, and find them root quite freely. The very hard and the very soft young growths are those which are most likely to fail when made into cuttings. It is easily known when the cuttings have formed sufficient roots to be ready for potting. They begin to grow freely when they have roots about three-quarters of an inch long; those that have been made by cutting up long shoots push young growths from the axils of the leaves, and when the roots are of the above length, is the proper time to pot them—for if left till they extend, they are so brittle that they cannot be handled without breaking them. In getting them out of the sawdust, place the fingers of the right hand under them, holding the cuttings in the left, and raise them gently out of the bed. Then give the stems a gentle tap with the finger, to knock all the sawdust out of the bunch of fine hairy roots; for if sawdust be left about them to any extent, it breeds fungus in the pots or baskets into which they are put.

The young plants may be put either into pots or small baskets made of wire or Teak. What I prefer is, to establish them first in small pots, and then transfer them to baskets; for Pitcher-plants show themselves best when suspended. For a large cutting 3-in. pots are of sufficient size. Thorough drainage is of the first importance; for though this genus of plants requires a great supply of water, it must never stagnate about their roots. The pots should therefore be a third full of charcoal, broken to the size of Broad Beans, and with the dust sifted out. The potting material which I prefer is fresh living Sphagnum Moss, and the fibre of the best Orchid peat, with all earthy particles sifted out of it—two parts of the former and one of the latter, well mixed together; and in the process or operation of potting a good few pieces of charcoal are mixed with it. A firm seat of this material is made for the base of the cutting and its whorl of roots to rest on. The pot is then carefully but firmly filled up, and slightly rounded off above the rim of the pot, as in potting Orchids. A stake is put to each plant, to which it is fixed, and they are then ready to be returned to the glass case or hand-glass again. Plunge them to near the rim of the pot, give them a thorough soaking of water, and keep them close and moist for a fortnight or three weeks; after which raise them out of the bottom-heat, and inure them by degrees to the air of the house or pit. They soon commence to grow freely, and can then be placed in any shady part of a moist stove not far from the glass. If bushy, dwarf basket-plants be the object, pinch the tops out of the plants, to cause them to break into several growths; but if rafter-plants be desired—especially in the case of *N. distillatoria*, *N. ampullacea*, and *N. Rafflesiana*—do not pinch them. Cuttings struck in early spring and managed thus are well established in their small pots, and ready for transfer into larger pots or baskets, as the case may be, about the middle or end of July. The material used for potting is the same as has already been described, with fully more charcoal mixed with it; and a few pieces of dry horse-droppings are added in the process of potting, and put chiefly near the surface of the pots or baskets. When shifted they can be suspended within 2 ft. or 3 ft. of the glass, in positions where they can be freely syringed every afternoon. Shade from the direct rays of the sun is necessary, and they require to have the material about their roots always moist. They thrive well hung up anywhere in a stove which is kept sufficiently moist and shady for stove-

plants that are grown for the beauty of their foliage, and they do not need half the care and attention that *Crotons*, &c., require. Early spring cuttings, treated as described, will furnish a good display of moderate-sized Pitchers the same autumn—and this is not much longer than the mere rooting of the cuttings takes under some of the old methods.

To grow *Nepenthes* into specimens varying in size according as the extent of accommodation at command may lead the cultivator to decide, it will be necessary to examine the young plants treated of above about the end of February or early in March; and if the pots or baskets be found well filled with roots, and the material in which they are growing adhering to them, they should be shifted into pots or baskets of larger sizes, always remembering that *Nepenthes* do not need a great amount of root-room—the chief points in their after-culture being to provide them with fresh living Sphagnum, and just the fibre of the most fibrous peat. They dislike, above all things, inert fine soil. The drainage should be perfect, and some pieces of charcoal should be mixed with the Sphagnum and peat. Any long, straggling growths which may have been produced should be shortened back soon after they are shifted; and the pieces cut off may be put in as cuttings. Provided *Nepenthes* be grown in material that suits them, they may be termed very easily-grown plants, their chief requirements being a liberal supply of water and daily syringing overhead. Some varieties, such as *N. distillatoria*, *N. ampullacea*, and other strong growers, are very suitable for training up the rafters of a plant-stove. To beginners who want to grow only a select few, I would recommend the following:—*Nepenthes Rafflesiana*, *N. Hookeri*, *N. distillatoria*, *N. hybrida maculata*, *N. Sedeni*, *N. Dominiana*, *N. intermedia*, and *N. lanata*.—"The Gardener."

Lælia pumila Dayana.—This welcome addition to dwarf winter-blooming Lælias was imported by Messrs. Low & Co., of Clapton, with whom (as well as with Mr. Day, of Tottenham) it has recently flowered. A remarkably vigorous plant of it was shown by Sir Trevor Lawrence, of Burford Lodge, Dorking, at a recent meeting of the Royal Horticultural Society, and received a first-class certificate. In habit and time of flowering it agrees with *Lælia pumila*, but the colours are much more effective, and the flowers are more shapely, and of a more wax-like texture. This plant and its ally *L. pumila* (*Cattleya pumila* or *C. marginata* of gardens), were imported together from the same habitat, and it is said that forms of it are almost wholly of a dark maroon-purple tint, the white-throated sub-variety being, however, the most beautiful.—B.

Propagating Santolinas.—A few old plants of these should be taken up in the autumn, cut close down, and potted; they should then be stored away in a cold pit or frame during winter, and in spring removed to the propagating pit. As soon as the young growths have attained 1 in. in length, they should be cut off with a sharp knife, and have the bottom leaves trimmed off; the cuttings should then be inserted in pots or pans, prepared as for *Verbenas*. The soil should be kept moderately moist, and as soon as the cuttings are rooted they should be removed to a cooler place and gradually hardened off. *Santolinas* will also strike root if taken off in the autumn and inserted in sharp sandy soil firmly trodden down; they should be put in firmly, and a hand-light placed over them. When struck abundance of air should be given them, but during sharp weather the lights should be put over them.—S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Echinocactus Cumingii.—I have now in flower a seedling of this species, saved from a plant in my possession, and which bears bloom of a pale primrose colour which turns almost white before fading. The flowers are perhaps hardly so large as those of the type. Out of the batch which I raised from one berry, I only retained two examples for my own collection, and the other, which is of slower growth, appears to promise flowers of the original colour, which Labouret calls yellow ochre. Cacti, like all other plants, of course vary occasionally from seed, but this is the first time I have seen this species of a different colour.—JOHN E. DANIEL, *The Terrace, Epsom.*

A Violet-scented Fern (*Aspidium fragrans*).—This is a low-growing little Fern, having short, finely-cut fronds which exhale a most delicate fragrance not unlike that of Violets. The plant forms radiating tufts of fresh green leaves, and it grows well in a close moist Wardian case or under a Fern shade, it deserves to become popular as a distinct and pleasing decorative plant. We have several other Ferns all more or less odorous, but none more desirable than this. It succeeds best in a fresh compost of turfy loam, peat, and sandstone grit, to which some living Sphagnum Moss may be added.—B.

TRAPS FOR INJURIOUS INSECTS.

WASPS, HORNETS, FLIES, &c.

THE numbers and fecundity of the Wasp in certain seasons are as well known as the mischief that they do to our fruit, and the annoyance that is caused by the dread of their sting. It is entirely our own fault, however that they trouble us in such numbers. If all the cultivators who have an interest in ridding themselves of the Wasp would give themselves the trouble, and come to some arrangement for united action, in a very short time the species would disappear. It appears, indeed that at

Fig. 1.

Thomery, near Fontainebleau, where every one destroys it because it attacks the Chasselas Grape whose cultivation is the trade of the country, the Wasp is now nearly unknown. Among the means employed for their destruction are some very simple traps. These are the bottles of which we give figures 1 and 2, in which is placed water sweetened with honey or sugar. The bottle (fig. 1) is hung easily along espaliers, and there destroys a great number of the insects which the ripe fruits (Pears, Peaches, Grapes) attract.

As to the apparatus represented by the fig. 2, it can also

Fig. 2.

be employed against Wasps, but is rather intended to destroy house flies, the scourge of country houses. A is a plate upon which rests the carafe C, and which is raised underneath and pierced by a large opening. The Flies enter there, but do not take the same course to get out, because they always try to rise: they fall into the soapy water with which the foot of the bottle is filled.

There is another still more energetic, but more dangerous means which is sometimes adopted in France, but which we do not recommend—flat dishes, such as plates, are hung by

three strings, in front of the espaliers. In these dishes is placed a mixture of syrup and arsenic: the syrup may be replaced by honey or any other analogous substance. All the Wasps soon fall dead on the ground. Unfortunately the Bees fall there at the same time, attracted by the same bait.

There was in the exhibition of 1867 a sufficiently original machine for catching Wasps and Hornets in their nests: it was a double cone, about 3 ft. in size, made of perforated metal, placed by means of a handle either on the ground upon the orifice of the nest of the common Wasp, or upon trees or walls over their nests for Hornets. The apparatus is placed at night when all the insects have gone home, and the base is surrounded by earth heaped up to prevent any amongst them from escaping. The Wasps ascend into the cone in the morning through a passage that is opened for them, and when safely entrapped they can be suffocated by brimstone or similar means.

A. M.

IN PALESTINE.

THE better acquainted I become with the country east of the Jordan, the more I am amazed at its fertility and natural resources. The scenery everywhere among the Gilead hills is picturesque and beautiful. The forests and cultivated fields, the green valleys and grassy slopes, remind one of the park scenery of England. The hills in many parts are well wooded, but besides this there are also dense forests of large fine old trees, such as are not elsewhere seen in this peeled and poverty-stricken land. The upper portion of Wady Yabis is called "el Akhdar," i.e. the green, and its gardens and orchards, as well as its fields of Grass, combine to render it a charming place. But Wady Ajlun surpasses the Yabis in respect to cultivation and beauty, because it is larger, and the fountains which feed its copious stream are at a much higher level in the mountains. Ain Jemeh is near the head of this Wady, and the fountains and streams flowing among the Olive trees and Walnut groves there make this one of the most delightful valleys in Syria. There are three other flourishing villages, Ajlun, Anjara, and Keferenji, all except the latter in the immediate neighbourhood of Ain Jemeh; and the valley at that point is full of ancient ruins, which extend clear up to Kallet er Rabad itself, showing that this locality has been occupied by towns or cities from remote times. At one place on this Wady I saw an orchard of unusual extent, in which there were at least eight kinds of fruit trees—the Fig, Olive, Apricot, Quince, Plum, Lemon, Apple, and the Pomegranate growing side by side. The valley is full of mills, flour-mills, of which I counted about twenty, but not all of them were in working order; and not only on this, but on many other streams as well, the number of ruined mills surprises one. For instance, on the line of the Zerka, or Jabbok, I counted between twenty and thirty ruined flour-mills, besides a very few that were in operation. I learn that in some cases the locality chosen for a site is not a good one, and the investment proves a failure; and in the more dangerous sections, as has doubtless been the case on the Zerka, the people have been either driven away or murdered, consequently the place and the business have been abandoned.—"Athenæum."

Sir Wyville Thomson on Patagonian Vegetation—Recently at a meeting of the Botanical Society of Edinburgh, Sir Wyville Thomson gave an address on "The Character of the Vegetation of Fuegia and Southern Patagonia." He stated that he had passed through the Straits of Magellan in the Challenger, and had taken the opportunity of landing on some of the islands at the west end of the channel. He had collected a considerable number of plants, which he had brought home with him, and which he presented to the Botanical Society. The vegetation of Fuegia, he remarked, was most curious. Its chief characteristic was the immense jungle of scrub and brush. The trees were not very large nor very close to one another, and so there was no appearance of a forest. Beeches were most commonly to be met with, and they were not very long-limbed, owing to the vast debris of old vegetation. When he (Sir Wyville) visited the district it was Christmas time, and consequently the depth of summer, and the plants were in full bloom. Among the creeping plants he noticed large bunches of the Mistletoe growing up the trunks of the trees. The ends of the Straits, he mentioned, were remarkably distinct in the character of their vegetation. The islands at the west end were exceedingly rich in plants, consisting mainly of a jungle of brush; while in the east the land was very low and covered with Grasses and low herbage, the trees being not nearly so tall. The general features of the vegetation of Fuegia were extremely like those of the southern parts of Norway and Sweden. The temperature only changed by a few degrees, and vegetables from our own country would not seed, owing to the few degrees of summer-heat. The lecture was illustrated by dried specimens of the plants described.

FLOWER VASES AND STANDS.

THE Royal Horticultural Society did useful work when some years ago it offered prizes for the best arrangements of flowers and fruits for the decoration of the drawing-room and dining-table; but the original and beautiful examples exhibited by Mr. March and others soon came to be lost sight of, and originality stifled, by the prizes for dinner-table arrangements being invariably given to the now stereotyped suite, consisting of either a central Palm of the Cocos Weddelliana type, flanked by two March stands filled with precisely the same mutilated flowers and Ferns, or to three March stands, the taller one being in the centre. The floral vases for the drawing-room table have been nearly universally neglected, although it is here, perhaps, that we find most scope for the really artistic—that is to say, the beautiful—arrangement of flowers, more especially hardy ones; although both hardy natives and tender exotics may often be combined in drawing-room vases with the best results, there is a great difference between the tastefully-filled vase found on the drawing-room or hall table in most old country houses and modern dinner-table vases; it is not, however, too late to mend, and what we now plead for is a more natural style of grouping in the last-named class of decoration. No good flower painter will ever hand down to posterity pictorial copies of our modern bouquets and groups of dinner-table flowers as Van Huysum has done in the case of floral vases of his time. The flower pictures of that and other artists may therefore serve to teach us how beautiful our drawing-room vases may, under tasteful management, be made. Our modern floral decorations, of which that now engraved is an example, however neat and graceful in form, never give us glimpses of floral luxuriance and tints of pure colour as do the old-fashioned masses of Lilies, Irises, Narcissis, and Tulips arranged with their own, and consequently most appropriate, leafage. Mr. Aldous did, however, recently exhibit a most original and graceful vase for the drawing-room table at South Kensington; it consisted of Solomon's Seal and one or two spathes of the white Arum Lily springing from a naturally-arranged base of filmy Maiden-hair Fern and coloured flowers; but both the judges and the press alike left it unnoticed. Modern floral arrangements for the dinner-table will certainly fall into disuse, owing to their formality and want of true artistic beauty. Not so vases skilfully filled with hardy flowers; such vases every true flower painter is pleased to imitate, and every lover of flowers to enjoy and admire.

F. W. B.

Artificial Flowers, called Barometers.—These are now being exhibited in a number of Parisian opticians' shops. They are coloured with a material composed of chloride of cobalt. When exposed to sun and dry air the leaves become deep blue; when the air is saturated with moisture, they become pinky. All the intermediate shades are easily observed.

Leaves.—The chemists of the German arboricultural and agricultural schools have made a thorough investigation into the properties and composition of forest tree leaves. They have found the chemical analysis of the leaves of several species of forest trees to be much richer in phosphates and other fertilizing ingredients, than they generally get credit for in this country, so much so that we would call the attention of all interested to their value as excellent litter when collected and kept dry till used, and very valuable manure they make, according to analysis given by the German chemists.—"Journal of Forestry."

PLATE LXXVII.

THE ARMENIAN GERANIUM.

Drawn by H. HYDE.

It is odd that, notwithstanding the number of years hardy Geraniums have been grown in our gardens, we should have now to figure the handsomest and most valuable of them all—*G. armenum*. Our plate, drawn by Mr. Hyde from a plant in Parker's nursery, gives a better idea of the plant than any verbal description could possibly do; however, it is difficult to render the true colour. It is a very robust perennial, sometimes 3 ft. in height, and is as hardy as a Dandelion. It flowers abundantly in midsummer, and sometimes in smaller quantities till late on in the autumn. One of its merits is, indeed, the startling abundance of its large and handsome flowers: as to culture it only requires planting in any ordinary garden soil; as to position, it will suit well for the mixed border, also for grouping with the finer perennials in beds and on the margins of shrubberies. Like other good plants, this came to us without any flourish of trumpets, without even its name being announced at first. The writer noticed it in flower in M. Boissier's garden near Lausanne in the summer of 1868, and, seeing that it was both new and very handsome, brought home a few seeds of it, which were given to Messrs. Backhouse of York. Messrs. Backhouse distributed it at first under the name of one of the older hardy Geraniums (*G. Lambertianum*). Dr. Regel, who obtained it from that firm, found it distinct from that species, and, imagining it to be a new one, figured it in the "Gartenflora" under the name of *Geranium Backhouseanum*. Soon afterwards M. Boissier, on being referred to, pronounced it to be his *G. armenum*, first introduced through him to the Botanic Garden at Geneva, where it first flowered in Europe. The plant is now easily obtainable in most nurseries where hardy plants are grown. It should find a place in every collection of hardy flowers. W. R.

Vase of Flowers.

Annual Candytufts.—Candytufts have long ranked amongst the most popular of hardy annuals, for they are very hardy, robust in growth, and remarkably free-blooming plants. From the Purple Candytuft and what is

known as the White Rocket, by dint of careful selection, several improved kinds have been obtained. The purple variety has been sub-divided into lilac, purple, and rose, all of which, when true to character, are very pretty, but they have a tendency to revert to the original type. The finest selection is the crimson, of which I have seen fine masses at Dedham. The new carmine variety, now in course of distribution, is said to be very fine in colour, but I have not seen it. The white Candytufts are also very effective, especially the best form of the Rocket Candytuft; a few years ago some dwarf kinds were introduced from the Continent, but the flowers were small and ineffective, and inferior to those of the English forms. Candytufts may be sown in autumn in light, warm, rich soil, and sufficiently thinned out early in spring, or they may be sown in spring as early as possible. They must have good soil if they are to be effective, and they must be thinned out at the proper time and attended to a little as they make growth. They are scarcely early enough to flower in ordinary spring gardens, but in the open border where they can be sown in large patches they form bright spots in May and June.—D.

TREES AND SHRUBS.

SABINE'S PINE.

(PINUS SABINIANA).

This beautiful glaucous, grey-coloured, long-leaved Pine was introduced into Britain from Upper California in 1832 by Douglas, then botanical collector to the London Horticultural Society, and was named in honour of Mr. Sabine, then secretary of that Society. Douglas describes the trees in their natural habitats as being "of tapering form, straight, and of regular growth, from 40 ft. to 120 ft. in height, 2 ft. to 12 ft. in circumference, and, when standing far apart or solitary, clothed with branches to the ground." Some few reach 140 ft. in height, but those are not of great circumference. The wood is white, soft, even-grained, and perhaps not very durable. The leaves are in threes, very rarely in fours, from 11 in. to 14 in. long, and drooping during winter. Since its introduction this tree has become extensively distributed throughout the country, but as a rule it has not succeeded well; indeed, it has been a most disappointing tree, except, perhaps, in a few favoured localities. At Holkar in Lancashire there is a fair specimen of it, and at Kew, too, it is succeeding tolerably well. Where it does thrive and grow vigorously and when it is clothed with its long, glaucous, drooping foliage, it is an object of singular beauty distinct both as regards feature and form. It is highly ornamental planted as a specimen tree in pleasure grounds or in the foreground amongst other Conifers of darker foliage in a Pinetum. It should be planted in sites quite sheltered from cutting and prevailing winds and where there is a good depth of rich vegetable or alluvial deposits; when planted in thin, poor soils and exposed to winds, it presents a ragged, miserable appearance, and its branches gradually become, as it gets old, almost divested of leaves; indeed, in such positions it has been known to perish outright. The idea, therefore, of *Pinus Sabiniana* ever becoming a useful timber tree in this country may be at once discarded. Its cones, it is said, are very remarkable, being about 12 in. long and rough and prickly on the outside; they grow in clusters round the branches, are recurved, press on the wood for support, and remain on the tree for several years. Statistics from any of your readers who may possess or know of good specimens of this tree would be interesting, stating age, height, present condition, soil, or geological formation, or any other particulars as to habit and suitability of climate.

Longleaf.

GEORGE BERRY.

Sabine's Pine (*Pinus Sabiniana*).

FORESTS AND OPEN SPACES.

THE bill introduced by Government for regulating the New Forest is, we understand, likely to meet with some opposition. The New Forest contains about 63,000 acres, a portion of which is barren moorland. A space of about 20,000 acres has been in past years reduced to a mere formal plantation of Oak and Fir, planted by successive Governments for the sake of timber. Over this area the Government is, under the present bill, to retain power of planting and replanting, but the remainder of the forest (with the exception of one private enclosure not dealt with under the bill) will be left open to the public, and that in its natural state, allowing of free growth and of various kinds of trees. The scheme prepared by the Commissioners for Epping Forest has only just been received. This scheme offers compensation, which some consider over-liberal, to the grantees—that is, those who have purchased pieces of land unlawfully enclosed by lords of manors in past years. Where such land has not been built upon or improved, it has been argued, against the grantees, that the amount the holders would expect would be the value of the land calculated on the basis of its agricultural rather

than its building value. Such, indeed, was the decision of the Master of the Rolls in the case of the grantee who was made a party to the suit to try the rights of grantees. But the Commissioners have recommended a higher rate of compensation. Very various opinions, however, are entertained as to the price which has been actually paid by the majority of the grantees. If it be the fact, as some affirm that, as a rule, this land has changed hands several times, and that the present holders have paid full value for it as building land, it is not unreasonable that they should be compensated on that scale, in spite of the land having been illegally enclosed. Others, however, say that, as a rule, 760 acres held by the grantees have only been purchased by them at agricultural price. Whichever basis of cultivation it is decided is the fair one to adopt with respect to the present owners, it appears quite just that the proposal should be adopted that the lords of the manors, who are under the scheme to receive one-tenth of the agricultural value of all unenclosed land in compensation for their rights, should have deducted from the sum to be so paid them whatever amount they have previously received for land unlawfully enclosed by them. The bill

for the Forest of Dean will not, it is understood, be proceeded with by the Government. All that is really needed can, there is no doubt, be done without any bill. The Crown has power to sell small pieces of land in the immediate neighbourhood of the villages for the purpose of building miners' cottages, which are much needed. Colonel Kingscote, on Friday night, denied that the Government did, in fact, exercise this power, but this omission, if real, it is hoped, will be remedied, and the rest of the forest be allowed to remain open. With regard to the smaller metropolitan open spaces, we are glad to notice that Mr. Whalley's bill has passed the House of Commons and is now before the House of Lords, under the charge of the Duke of Westminster. Its main object is to enable the Metropolitan Board of Works to accept and maintain open spaces handed over to them without a special Act in each case. This provision is very important just now, when many London parishes may be prepared to follow the example of St. George-in-the-East and St. Martin-in-the-Fields, and allow their disused churchyards to be planted and used as public gardens. For the one sake of the poor districts it seems more fair that the cost of such planting and maintenance should be borne by a Metropolitan than a local rate, though

A Highland Forest for the Queen.—It is stated that the arrangements are almost completed for the purchase by Her Majesty from Colonel Farquharson, Invercauld, of the forest of Ballochfine, which adjoins the estate of Balmoral. The forest is on the estate of Invercauld, and comprises within its grounds the largest area of naturally grown Scotch firs in Scotland. It is unequalled for the size, beauty, and symmetry of the trees. Ballochfine has been held by the Queen on lease for a number of years at an annual rent of £1500 sterling.

we admire the spirit with which the two vestries have come forward in the instances we have cited. All these Bills are being carefully watched by the Commons Preservation Society, which in past sessions has been instrumental in initiating proceedings which have resulted in preserving Hampstead Heath, Plumstead, Wimbledon, Wandsworth Commons, and many others, and which this session has successfully opposed railway encroachments threatened to Mitcham and Barnes.

"Whangee" Walking Canes.—Under the name of "Whangee," a jointed Bamboo is, according to the Linnean Society's Journal, imported in considerable quantities into this country, it is said from China, for the manufacture of walking-canes. For a long time the scientific name of the plant producing these canes was quite unknown; latterly, however, they have been attributed to the genus *Phyllostachys*, *P. nigra* being the species chiefly accredited with their production; on this point, however, there is still some doubt. From whatever species of Bamboo they may be produced, one thing seems clear, that the "Whangee" canes, as seen in trade, are not the stems proper, as is generally supposed, but the underground stems, the small circular markings surrounding each joint being the scars whence the roots have been given off, and the indentations on the alternate sides the points from which the aerial stems have arisen. The aboveground stems assume a different character, being, of course, minus the root-scars, which is a distinguished mark and a point of beauty in the commercial cane. Thus two distinct canes seem to be produced by the same plant, one from the underground, and the other from the aboveground stem. A specimen which I have from a plant grown at Chatsworth, seems to me sufficiently to illustrate this. One thing is remarkable, that all the imported "Whangee" canes are white, while the English-grown specimen is black. This I can account for only by supposing the former to be systematically bleached at the same time that they are straightened before exportation. The length required for a walking-stick is perhaps unusual for the rhizome of a Bamboo; but this may be attained by keeping the stem buried beneath the soil until it has grown to a sufficient length. That this may be done as a system is possible, when we know that in Algeria the young sticks of the Medlar are gashed transversely, while they are growing, to give them a knotted appearance, and so enhance their value in the market.

Ivy on Houses.—Horticultural journals have lately been discussing the question whether or not a covering of Ivy makes a house damp. Of course, the Ivy clambering up the gable of a house cannot make the house damp, any more than a topcoat can make a man's underclothing damp; on the contrary, it will tend to preserve it dry. If, however, the rain be sufficiently heavy to penetrate the covering of Ivy and to wet the wall, the fact of the Ivy keeping out wind and sun will, of course, tend to keep it wet, just as a topcoat would keep underclothing wet if the rain had drenched the wearer to the skin. Ivy is undoubtedly very bad in this respect in positions where the wet from any special cause is liable to drive in behind it. A faulty spout or an awkward bit of roof may sometimes be found to shoot the water down at the back of the Ivy. In this case the covering of green would do for a wall very much what a topcoat would do for the man whose umbrella poured all the rain down inside his coat collar. The leak in the spout, or the faulty construction of the roof, which might only stain the outside of the bare wall, would be sufficient to completely saturate and permeate the wall covered with Ivy. In such a case the wiser plan would be stop the downpour of water; the more obvious plan, however, is to strip down the greenery, and as this will be followed by speedier drying of the external wall, the interior dampness may disappear also, and the Ivy will be debited with the mischief. All this seems so obvious as to be scarcely worth pointing out. Yet it is owing to the neglect of these obvious considerations that a common prejudice has arisen against this beautiful parasite, which Nature seems so kindly to have provided for the special purpose of hiding the dreary ugliness of what Mr. Ruskin calls our packing-cases. With roofs and spouts in good condition, and especially with a projecting eave over it, Ivy is as beneficial as it is beautiful, and is not used a tenth part as much as it should be.—"Globe."

A Noble Oak.—Mr. Wilson, of Shrewsbury, lately purchased from Colonel Edwards, Great Ness, a fine Oak, supposed to be the largest sound tree in Shropshire. At 5 ft. from the ground it measured 20 ft. in circumference, or 7 ft. in diameter, and with its immense tops contained upwards of 600 cubic ft., and produced about three tons of bark. The total estimated weight is at least thirty tons. An Oak is said to have been felled near Newport, in Monmouthshire, in 1810, measuring 28½ ft. in circumference. It was supposed to be 400 years old, from the number of rings in the grain; and it was stated at the time that the timber sold for £670 and the bark for £200.

THE LIBRARY.

CULTIVATED PLANTS.*

MR. BURBIDGE needs no introduction to the readers of THE GARDEN, who are indebted to him for so many literary and pictorial illustrations, and the favourable estimate which they will have formed of his qualifications cannot fail to be increased by the careful perusal of the handsome volume which now lies before us. Connected at the commencement of his calling with the Royal Horticultural Society's gardens at Chiswick, passing on subsequently to Kew, and making ample use of the opportunities offered him by each of these institutions, it is not to be wondered at that Mr. Burbidge has produced a book full of information, both original and compiled. We learn from the preface that, while primarily intended "as a popular handbook in plant propagation and improvement," it is also meant to "serve young gardeners as a stepping-stone to works of a higher scientific character, and more especially to those of Charles Darwin." Both of these objects it is eminently qualified to accomplish: but it is, moreover, a book which will have an interest for very many besides the class for whom it is especially intended. The amateur gardener cannot fail to benefit by the good practical advice given on such matters as seed-saving and seed-sowing, propagation by division, layers, and cuttings, or by grafting and budding; while the summary of observations upon hybridizing, cross-breeding, and artificial fertilization abound with useful hints to those who dabble in these interesting branches of experimental horticulture. This part of the volume—and, indeed, the whole of it—is eminently suggestive; in fact, if we were asked to select one epithet by which to characterize the book, the one just mentioned would be that which we should choose. Thus, speaking of cuttings, Mr. Burbidge says:—"It is curious to observe that while many gardeners strike *Ericas*, *Epacris*, and *Azaleas* readily from cuttings, they rarely, if ever, think of attempting to propagate new or rare *Conifers*, or hardy evergreen and deciduous shrubs in the same way. How often do we see, in looking over a great garden, *Dracenas*, *Ericas*, *Crotons*, *Gardenias*, and other exotics propagated by the hundred; but how rarely are we shown a batch of young *Hollies*, *Abies*, *Piceas*, or a pan filled with rooted cuttings of some rare and beautiful hardy *Conifer* or ornamental shrub!"—and yet the one is just as easy to propagate from cuttings as the other. Again, in another passage—"It should always be borne in mind that our fruit tree culture is unnatural, that is, we do not want a crop of natural fruit, but enormous crops of unnatural ones, that is to say, the more the succulent seed-vessels exceed the seed in propagation, the better we are pleased." It would be impossible to put more strongly the aim of artificial as opposed to natural selection, the former tending to the benefit of the species, the latter to that quality in it which is of most importance to man. The practical gardener will find in the "propagator's calendar," with which the volume concludes, succinct but sufficient directions for his guidance in this branch of his profession during each month of the year.

The bulk of the work is occupied with a general review of some of the most popular groups of cultivated plants, with notes on their propagation and natural affinities. This is somewhat oddly arranged alphabetically under the Latin names of the different natural families. It contains a sketch of the horticultural history of each group, especial attention being paid to the hybrids, the origin of which is given wherever possible, and the author's acquaintance with the literature of the subject is manifest throughout. Foreign and English gardening periodicals are freely quoted, and many interesting facts, which would probably be lost sight of in such journals, are brought under notice, and thus rescued from forgetfulness or obscurity. References to published figures render this portion of the work still more complete and useful. While work done is thus fully chronicled, suggestions for future experiments are thrown out when necessary. Thus, for example, speaking of the *Palmaceae*, Mr. Burbidge writes:—"It is rather singular that none of our lynx-eyed propagators have suc-

* "Cultivated Plants: their Propagation and Improvement." By F. W. Burbidge. London: Blackwood, 1877.

ceeded in hybridising Palms. Their bisexual flowers would rather facilitate cross-breeding than otherwise; and if fruit-bearing plants can be procured of *Cocos Weddelliana*, *Chamaerops humilis*, *Calamus ciliaris*, or any of the dwarf-growing species of *Geonoma*, *Areca*, or *Chamaedora*, pollen could in most cases be procured from such allied species or genera as continue flowering nearly all the year round in one or other of our great botanic or public gardens." The only hybrid Palm mentioned by Mr. Burbidge is one obtained by M. Denis, of Hyères, by fertilizing a variety of *Chamaerops humilis* with the pollen of the Date Palm (*Phoenix dactylifera*). Attention is also especially directed to the *Melastomaceae*, in which group little has been done by hybridizers, although the few results obtained have been remarkably beautiful. Some of the important results which have been produced from apparently accidental variations are duly chronicled, such as the Suffolk Wheat, which originated about thirty years since with an Ipswich farmer, "merely by the accident of a very fine ear sticking behind the button of his coat as he was one day descending the ladder from the mow." The Potato Oat is the result of a single stalk which was found growing in a Cumberland Potato field fifty years ago; and, among fruits, the Black Eagle Cherry (which, on its first fruiting, was condemned by the Fruit Committee of the Horticultural Society), owed its preservation "to the intercession of one of Mr. Knight's children, who had planted the stone from which it sprang, and so one of our best Cherries was preserved to our gardens." The Irish Yew, again, which is doubtless a chance seedling from the common Yew, was "found in 1780 on a mountain near Benoughlin, whence it was introduced to the gardens at Florence Court, the residence of Lord Enniskillen, and from this solitary example all those now grown have originated." We believe that the well-known Purple Beech, now so frequent in gardens, is stated to have originated in a natural sport found in a forest in Germany. The Pansy, which is supposed to be a cross between *V. tricolor* (the Wild Heart's-ease of our corn-fields), and *V. altaica*, was first raised by Lady Mary Bennet, assisted by her gardener, Mr. Richardson, at Walton-on-Thames, about 1810 or 1812. The Foxglove is one of the plants which Mr. Burbidge commends to the notice of his readers, saying, truly enough, that if some intelligent florist would but take up its improvement, it would soon become one of the handsomest of hardy garden flowers. It is strange, indeed, that this matter of the improvement and utilization of our wild plants has not been taken up more extensively, there are so many of them which would probably amply repay any trouble which might be spent on them, such, for example, as the common blue Germander Speedwell (*Veronica Chamædrys*), which might soon be made into a very useful border plant for spring bedding.

It should be mentioned that the volume under notice is rendered additionally attractive by some excellent woodcuts. It is almost certain to reach a second addition, in which case we trust that the somewhat large crop of typographical errors will be reduced, and that the cover will be adorned with some more artistic device, or failing this, be left plain; for the singular combination of a plant of *Lagurus* (?) and an Acorn germinating in a way hitherto unheard of is neither accurate nor artistic. When we have said that there is a very full and excellent index, and that the book, from one cover to the other, is full of useful information and practical suggestions, we are of opinion that we shall have sufficiently commended it to the notice and careful perusal of all readers of THE GARDEN.

B. J.

"THE AMERICAN FRUIT CULTURIST." *

This is an admirable book by an experienced and able cultivator, long accustomed to express himself with clearness and force in writing on pomology. It is a model of clearness and thoroughness, and is illustrated with over 500 accurate illustrations. The present is the eighth revised edition. The first edition of the "Fruit Culturist," the basis of the present work, was written more than twenty years ago, and a year before the appearance of Downing's first edition of the "Fruits

"The American Fruit Culturist." By J. J. Thomas. New York: W. Wood & Co.

and Fruit Trees of America." It was subsequently much enlarged, and several revised editions afterwards appeared. The rapid progress made of late years in the culture of fruit has required a still further revision. The present edition has been newly arranged, and most of it rewritten. Being intended as a guide to the practical cultivator, its object is to furnish useful directions in the management of the nursery, fruit garden, and orchard, and to assist in the selection of the best varieties for cultivation. It does not claim to be a complete work on the pomology of the country, but aims to give full descriptions only of valuable or promising fruits suited to the country at large, or which may have been popular in certain districts. Varieties which are very little known, whose position or value is undetermined, or which have been found unworthy of further attention, are consigned to the general descriptive list and index, where their leading characteristics are briefly noticed. As some confusion would result from a promiscuous assemblage of all the different varieties, a systematic arrangement has been adopted for the principal fruits. By placing them under separate and characteristic heads, the cultivator is enabled to distinguish and remember each sort with more readiness than where all are thrown indiscriminately together. The names of those fruits which have been proved of the greatest general value, or which have received a large vote in their favour, either in particular regions or throughout the country, are distinguished by being printed in small capitals. One of the chief points for determining the classification is the time of ripening; and the principal fruits are separated into summer, autumn, and winter sorts. As the time of ripening, however, varies several weeks in different parts of the country, and no exact line could be drawn for these three divisions, it would be strictly correct to classify them as early, medium, and late. With this understanding, however, the terms used will answer the purpose, and will not mislead. It is pleasant to think of the impetus to good fruit culture such a book gives in land with such an excellent climate for fruit-growing in nearly all parts of its vast extent. Although concerning what is to us for the most part a new world of fruits, the book has many chapters of value to cultivators everywhere, and we shall probably, at a future time, reprint some of the matter of most interest to the English reader. With a fine sunny climate, abundance of land, and advisers such as the author of this, it is not surprising that the Americans are supplying the markets of Europe as well as their own country with hardy fruits.

Early Vegetables in New York.—"The Grocer" gives the following information in regard to the early vegetables sent to the New York market:—Among the first vegetables to arrive in this market is Asparagus. Our first supply comes from California, and is shipped in the ice cars containing salmon; it brings about 3s. per bunch. A little later on we receive Asparagus from Florida at 4s. per bunch. Gradually as the season advances, our sources of supply work northward to Savannah, Charleston, Norfolk, until about the first of May, when the product of the New York market gardens begins to appear. California also has the honour of supplying us with the first Cauliflower, which is shipped in the same manner as Asparagus, and is worth when it first appears about 4s. per head. Among the most prominent of our January arrivals may be mentioned Cucumbers and Lettuces, the first arrivals of both of which we receive from Massachusetts. The first Cucumbers to arrive are very large, measuring from 12 in. to 14 in. in length, and cost sometimes as much as 10s. each. About the middle of June, when the season is at its height, 3d. each is more than can be realized by the New Jersey and Long Island product. Lettuces come also from the Boston hothouses, and are worth 4s. per dozen. In May we begin to receive Lettuces from Long Island at half that price. Canada also contributes her part towards supplying us with luxuries by sending down the finest Rhubarb and Mushrooms received here. The latter are grown in large galleries 20 ft. underground, on the estate of Col. Rhodes, near Quebec. Green Peas have begun to arrive in small quantities. Early Potatoes, Onions, and Tomatoes, come from Bermuda at first, and later in the season from Savannah, Charleston, and Norfolk.

Rye.—It is usually thought that Wheat is the most nutritious of all our cereals, and this opinion is current in almost all works relating to food. Recent investigations by Professor Wanklyn and Mr. Cooper appear to show the contrary. They give the first place to Rye. Rye contains more gluten. It is one-third richer than Wheat. Rye, moreover, is capable of thriving in almost any soil. This fact ought to have an important bearing now that Wheat is rising to war prices.

THE TREES OF PARIS.

THE first thing that strikes an English visitor to Paris is the height and bright aspect of the houses and the abundance of trees, the verdure of which, especially at this season, imparts an air of freshness and beauty on all sides. The English traveller, on issuing from the Gare du Nord, that is to say the station of the French "Great Northern," and driving to one of those favourite quarters of New Paris which have sprung up around the Arc de l'Etoile, will pass along a series of streets, avenues, and boulevards all rendered charmingly fresh and attractive by rows of well-selected trees—first, perhaps, an avenue of Horse Chestnuts, now in full bloom; next, a long line of Paulownias, every branchlet terminated with a spike of purple Foxglove-like flowers, which have given to the Paulownia its popular name, the "Foxglove Tree," just as the Horse Chestnut well deserves, though it has not yet received, the name of the "Hyacinth Tree." In other places Limes are substituted, and I noticed that an avenue of *Ailantus glandulosa*, with its tropical-looking pinnate foliage, produced a charming and luxuriant effect; while in other places the

are filled to repletion with a profusion of flowers that appear to enjoy, and even luxuriate, in their position; and the external palisading, generally of good design and touched with a little judicious gilding, is often, up to a certain height, converted into a pleasant green wall by means of Ivy closely trained to a wire netting, as represented in a recent number of THE GARDEN, making their prison walls an ornament to their captivity. Sometimes this pretty screen of greenery terminates at the height of 4 ft. or 5 ft. in an unbroken and carefully-maintained horizontal line, often in a waved line, and sometimes in a series of escalops, either concave or convex the concave producing, of the two, the more agreeable effect. Many of the new boulevards and avenues of New Paris, in addition to ample trees, are bordered on either side by broad spaces of turf ornamentally planted with flowering shrubs and flower-beds. In these street edgings, as one may fairly term them, the Horse Chestnuts—white and red—Lilacs, Laburnums, and Hawthorns, being just now in full bloom, and brought into absolute luxuriance by the few sunny days which have been so long waited for, impart to the avenues so

Gardens near the Louvre.

Oriental Plane plays a distinguished part. The comparatively smokeless atmosphere of Paris is, it must be admitted, far more favourable to tree growth than that of London; but we might do very much more than has been yet attempted, and if the use of smoke-consuming fire-grates were enforced, there is no reason why London should not rival Paris in the attractive feature of street trees. The beautifully warm and creamy-toned stone of Montmartin, of which the greater part of Paris is built, is one of the secrets of the attractive aspect of the buildings, which conveys at once an impression that causes the traveller involuntarily to exclaim, "Paris is beautiful." Even while passing through the comparatively simple architecture as that presented by the houses of the Boulevard des Batignolles and other third-rate thoroughfares of New Paris, such an exclamation is amply justified; but when he approaches the immediate region of the Arc de l'Etoile and the upper portion of the Champs Elysées, the traveller can scarcely refrain from exclaiming "Paris is superb!" Indeed, the combination of fresh foliage with bright and stately architecture is not to be matched in any other city of the world. The small gardens in front of houses of superior character

treated a lavishness of beauty that, heightened by the long rosy tresses of a kind of Tamarisk hanging in the lovely position of showers of flowers, makes these plantations seem rather the pathways of some fairy city, such as one reads of sometimes but never sees, than the ordinary streets of a European metropolis—yet which are absolutely realised in this wonderful New Paris. At the west end of London something similar might be effected in many situations ready to hand, if only the taste of those who rule such matters in England could be just a little educated. In Westbourne Terrace, for instance, there is a space on either side of the carriage road already planted with shrubs; but they are so closely shut up within stucco walls and balustrading of the same shabby material, that the necessary amount of light and air is denied them, and they always look miserable and unattractive in their continuous struggle for bare life; whereas, if the balustrading of sham stone were swept away, and the black soil between the shrubs clothed with fresh green turf, carefully tended, and renewed as often as required, then with some little ingenuity exercised in the choice of such shrubs and flowers as would be sure to enjoy themselves in that situation, something very bright,

open and pretty might be effected, in place of the dingy attempt at the introduction of a little foliage which is at present rather an eyesore than an ornament, and the exchange of which for more open space would be a positive gain. Our authorities would cavil at the phrase, "turf which should be carefully tended and renewed as often as required." They would shrug their shoulders, and ask, "who is to bear the expense?" Do they imagine that Paris has been made as beautiful as it is, and maintained, without expense. Why, I find that each tree that lends its leafy beauty to these endless avenues and boulevards costs the Municipality of Paris 100 francs a year. The first outlay is a mere trifle in comparison with the steady and continuous expense that is required, but could a certain amount of public money be better spent than in the

have no hope of seeing in London anything like the tree beauty of Paris.

NOEL HUMPHREYS.

The Fern-leaved Aralia (A. filicifolia).—This very elegant, fine-foliaged plant has stems of a deep olive colour, blotched with pale green; the leaves are dark green, glabrous, twice pinnately divided, with a single lobe at the end; the pinnae are about eight in number on each side of the midrib, each one being divided nearly to the base into linear, minutely saw-toothed and spine-pointed segments. The younger leaves are more finely cut than those first formed. It was exhibited last year at the Brussels International Exhibition, under the title of *Aralia spectabilis*; but the name of *A. filicifolia*, which was given to it by its discoverer, Mr. Charles Moore, has taken precedence. It was introduced, we believe, by

The Fern-leaved Aralia (*A. filicifolia*).

healthful and beautiful adjunct of trees and flowers to every great centre of civilization? Economy and tight pocket buttoning are doubtless civic virtues which have contributed their share towards the wealth and prosperity of England—but virtues of that class may be overdone. I have known model Englishmen, of good means, good education, and possessing many good qualities, who were such utter slaves to this British virtue of tight pocket buttoning—that they have strongly objected to taking a house with a garden, on the sole account of the expense of "keeping it up." These gentlemen have defended their views to me by declaring that they really have "no objection to flowers"—but that "keeping up" a garden of their own, seemed to them a weak-minded waste of money. Till such views are greatly moderated, we can

Mr. B. S. Williams, of Holloway, from the South Sea Islands.

The North American Papaw Trees.—In our collections of trees it is rare to find the North American Papaw, and yet to many its fruit is very agreeable and refreshing, quite as much so as the Banana. The tree is entirely hardy, of rapid growth, curious in flower, and an abundant bearer. Chapman in his "Flora of the Southern States" enumerates three other species, which may be designated, according to their several peculiarities, as Small-flowered, Great-flowered, and Dwarf Papaw. These are all shrubs, and may not prove hardy in the North, unless we except the first of them, which has the highest northern limits of growth. The Papaw is the only representative which we possess of an otherwise tropical family of edible-fruited trees. Prominent among its members may be mentioned the Custard Apple and the Sour Sop of the West Indies, and the Sweet Sop, native of the Malay Islands. The cultivation of the native Papaw is of the very easiest character, either by seeds or suckers, and it may be grown in almost any kind of soil. As an ornamental tree it is deserving of notice.—"Weekly Tribune."

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 459).

Mints.

Perdita. Here's flowers for you,
Hot Lavender, Mints, Savory, Marjoram.
Winter's Tale, act iv., sc. 3.

The Mints are a large family of highly-perfumed, strong-flavoured plants, of which there are many British species, but too well known to call for any further description.

Mistletoe.

Timon. The trees, though summer, yet forlorn and lean,
O'ercome with Moss, and baleful Mistletoe.
Titus Andronicus, act ii., sc. 3.

The Mistletoe was a sore puzzle to our ancestors, almost as great a mystery as the Fern. While they admired its fresh, evergreen branches, and pretty transparent fruit, and used them largely in the decoration of their houses at Christmas, they looked on the plant with a certain awe. Something of this, no doubt, arose from its traditional connection with the Druids, which invested the plant with a semi-sacred character, as a plant that could drive away evil spirits, yet it was also looked upon with some suspicion, perhaps also arising from its use by our heathen ancestors, so that, though admitted into houses, it was not (or very seldom) admitted into churches. And this character so far still attaches to the Mistletoe, that it is still never allowed with the Holly and Ivy and Box to decorate the churches, and Gay's lines were certainly written in error:—

Now with bright Holly all the temples strow,
With Laurel green and sacred Mistletoe.

The mystery attaching to the Mistletoe arose from the ignorance as to its production. It was supposed not to grow from its seeds, and so how it was produced was a fit subject for speculation and fable. Virgil tells the story thus:—

Quale solet sylvis brumali frigore viscum,
Fronde vivere novæ, quod non sua seminat arbos
Et creceo fetu teretes circumdare truncos.
Æneid, vi., 205.

In this way Virgil elegantly veils his ignorance, but his commentator in the eighteenth century (Delphic Classics) tells the tale without any doubts as to its truth. "Non nascitur e semine proprio arboris, at neque ex insidentium volucrum fimo, ut putavere veteres, sed ex ipso arborum vitali excremento." This was the opinion of the great Lord Bacon; he ridiculed the idea that the Mistletoe was propagated by the operation of a bird as an idle tradition, saying that the sap which produces the plant is such as "the tree doth excrete and cannot assimilate." So that we need not blame Gerarde when he boldly said that "this excrecence hath not any roote, neither doth encrease himselfe of his seed, as some have supposed, but it rather commeth of a certaine moisture gathered together upon the boughes and joints of the trees, through the barke whereof this vaporous moisture proceeding bringeth forth the Mistletoe." We now know that it is produced exclusively from the seeds probably lodged by the birds, and that it is easily grown and cultivated. It will grow and has been found on almost any deciduous tree, preferring those with soft bark, and growing very seldom on the Oak. Those who wish for full information upon the proportionate distribution of the Mistletoe on different British trees will find a good summary in "Notes and Queries," vol. iii., p. 226.

Moss.

(1) *Adriano.* If ought possess me from thee it is dross,
Usurping Ivy, Brier, or idle Moss.
Tempest, act iv., sc. 1.

(2) *Timon.* The trees, though summer, yet forlorn and lean,
O'ercome with Moss and baleful Mistletoe.
Titus Andronicus, act ii., sc. 3.

(3) *Apemantus.* These Mossed trees
That have outlived the eagle.
Timon of Athens, act iv., sc. 3.

(4) *Holspur.* Steeples and Moss-grown towers.
1st Henry IV., act iii., sc. 1.

(5) *Oliver.* Under an Oak whose boughs were Mossed with age,
As You Like It, act iv., sc. 3.

(6) *Arviragus.* The ruddock would,
With charitable bill,
Bring thee all this;
Yea, and furr'd Moss besides when flowers are none,
To winter-ground thy corse.
Cymbeline, act iv., sc. 2.

If it were not for the pretty notice of Moss in the last passage (6), we should be inclined to say that Shakespeare had as little regard for "idle Moss" as for the "baleful Mistletoe." In his day Moss included all the low-growing and apparently flowerless carpet plants which are now divided into the many families of Mosses, Lichens, Club Mosses, Hepaticæ, Jungermanniæ, &c., &c. And these plants, though holding no rank in the eyes of a florist, are yet deeply interesting, perhaps no family of plants more so, to those who have time and patience to study them. The Club Mosses, indeed, may claim a place in the garden if they can only be induced to grow, but that is a difficult task, and the tenderer Lycopodiums are always favourites when well grown among greenhouse Ferns; but for the most part, the Mosses must be studied in their native haunts, and when so studied, they are found to be full of beauty and of wonderful construction. Nor are they without use, and it is rather strange that Shakespeare should have so markedly called them "idle," or useless, considering that in his day many medical virtues were attributed to them. This reputation for any medical virtues they have now all lost, except the Iceland Moss, which is still in use for invalids; but the Mosses have other uses. The Reindeer Moss (*Cladonia rangiferina*) and Rock-hair (*Alectoria jubata*) are indispensable to the Laplander as food for his reindeer, and *Usnea florida* is used in North America as food for cattle; the Iceland Moss (*Cetraria islandica*) is equally indispensable as an article of food to all the inhabitants of the extreme North; and the Tripe de la Roche (*Gyrophora cylindrica*) has furnished food to the Arctic explorers when no other food could be obtained, while many dyes are produced from the Lichens, especially the Cudbear (a most discordant corruption of the name of the discoverer, Mr. Cuthbert), which is the produce of the Rock Moss (*Lecanora tartarea*). So that even to us the Mosses have their uses, even if they do not reach the uses that they have in North Sweden, where, according to Miss Bremer, "the forest, which is the countryman's workshop, is his storehouse, too. With the various Lichens that grow upon the trees and rocks, he cures the virulent diseases with which he is sometimes afflicted, dyes the articles of clothes which he wears, and poisons the noxious and dangerous animals which annoy him."—(Quoted from Macmillan's—"Footsteps," &c.).

As to the beauty of Mosses and Lichens we have only to ask any artist or go into any exhibition of pictures. Their great beauty has been so lovingly described by Ruskin ("Modern Painters"), that no one can venture to do more than quote his description. It is well known to many, but none will regret having it called to their remembrance—"placuit semel—decies repetita placebit"—space, however, will oblige me somewhat to curtail it. "Meek creatures! the first mercy of the earth, veiling with hushed softness its dentless rocks: creatures full of pity covering with strange and tender honour the sacred disgrace of ruin, laying quiet fingers on the trembling stones to teach them rest. No words that I know of will say what these Mosses are; none are delicate enough, none perfect enough, none rich enough. . . . They will not be gathered like the flowers for chaplet or love-token; but of these the wild bird will make its nest and the wearied child its pillow, and as the earth's first mercy so they are its last gift to us. When all other service is vain from plant and tree, the soft Mosses and grey Lichens take up their watch by the headstone. The woods, the blossoms, the gift-bearing Grasses have done their parts for a time, but these do service for ever. Trees for the builder's yard, flowers for the bride's chamber, corn for the granary, Moss for the grave."

Mulberries.

(1) *Titania.* Feed him with Apricocks and Dewberries,
With purple Grapes, ripe Figs, and Mulberries.
Midsummer Night's Dream, act iii., sc. 1.

(2) *Colymbia.* Thy stout heart
Now humble as the ripest Mulberry
That will not bear the handling.
Coriolanus, act iii., sc. 2.

- (3) *Prologue.* Thisbe tarrying in Mulberry shade.
Midsummer Night's Dream, act v., sc. 1.
 (4) The birds would bring him Mulberries and ripe red Cherries.
Venus and Adonis (see Cherries).

We do not know when the Mulberry, which is an Eastern tree, was introduced into England, but probably very early. We find in Archbishop Elfric's Vocabulary, "morus vel rubus, mor-beam," but it is doubtful whether that applies to the Mulberry or Blackberry, as in the same catalogue Blackberries are mentioned as "flavi vel mori, blace-berian." There is no doubt that Morum was a Blackberry as well as a Mulberry in classical times. It is probably the fruit mentioned by Horace—

Ille salubres
 Æstates peraget, qui nigris prandia moris
 Finiet ante gravem quæ legerit arbore solem.
Nat. ii., 4, 21.

And it certainly is the fruit mentioned by Ovid—

In duris hæreant mora rubetis.—*Metam.*, i., 105.

In the dictionaries of John de Garlande (thirteenth century) we find, "Hec sunt nomina silvestrium arborum, qui sunt in lucco magistris Johannis; quercus cum fago, pinus cum lauro, celsus gerens celsa," and Mr. Wright translates "celsa" by "Mulberries," without however giving his authority for this translation. But whenever introduced, it had been long established in England in Shakespeare's time. Gerarde describes it as "high and full of boughes," and growing in sundry gardens in England, and he grew in his own London garden both the Black and the White Mulberry. Lyte also, before Gerarde, describes it, and says:—"It is called in the fayning of Poetes the wisest of all other trees, for this tree only among all others bringeth forth his leaves after the cold frostes be past."

As an ornamental tree for any garden, the Mulberry needs no recommendation, being equally handsome in shape, in foliage, and in fruit. It is a much prized ornament in all old gardens, so that it has been well said that an old Mulberry tree on the lawn is a patent of nobility to any garden; and it is most easy of cultivation; it will bear removal when of a considerable size, and so easily can it be propagated from cuttings that a story is told of Mr. Payne Knight that he cut large branches from a Mulberry tree to make standards for his clothes-lines, and that each standard took root, and became a flourishing Mulberry tree.

Though most of us only know of the common White or Black Mulberry, yet, where it is grown for silk culture (as it is now proposed to grow it in England, with a promised profit of from £70 to £100 per acre for the silk, and an additional profit of from £100 to £500 per acre from the grain (eggs)!), great attention is paid to the different varieties; so that M. de Quatrefuges briefly describes six kinds cultivated in one valley in France, and Royle remarks, "so many varieties have been produced by cultivation that it is difficult to ascertain whether they all belong to one species; they are," as he adds, "nearly as numerous as those of the silkworm" (Darwin).

We have good proof of Shakespeare's admiration of the Mulberry, in the celebrated Shakespeare Mulberry growing in his garden at New Place at Stratford-on-Avon. "That Shakespeare planted this tree is as well authenticated as anything of that nature can be . . . and till this was planted there was no Mulberry tree in the neighbourhood. The tree was celebrated in many a poem, one especially by Dibdin, but about 1752, the then owner of New Place, the Rev. Mr. Gastrell, bought and pulled down the house, and wishing, as it should seem, to be 'damned to everlasting fame,' he had some time before cut down Shakespeare's celebrated Mulberry tree, to save himself the trouble of showing it to those whose admiration of our great poet led them to visit the poetick ground on which it stood" (Malone). The pieces were made into many snuff-boxes and other mementoes of the tree.

Mushrooms.

- (1) *Prospero.* You demy-puppets, that
 By moonshine do the greensome ringlets make,
 Whereof the ewe not bites, and you whose pastime
 Is to make midnight Mushrooms.
Tempest, act v., sc. 1.
 (2) *Aja.* Toad's-stool, learn me the proclamation.
Troilus and Cressida, act ii., sc. 1.

I join these two passages together because the first, besides the notice of the Mushroom, contains also the notice of fairy-rings, which are formed by fungi, though probably Shakespeare knew little of this; but the two passages contain his whole fungology; and it is not much to be wondered at that he has not more to say about them. In his time "Mushrooms or Toadstooles" (they were all classed together) were looked on with very suspicious eyes, though they were so much eaten that we frequently find in the old herbals certain remedies against "a surfeit of Mushrooms." Why they should have been connected with toads has never been explained, but it was always so:—

The grieslie Todestoole growne there mought I see,
 And loathed paddocks lording on the same.
Spenser.

They were associated with other loathsome objects besides toads, for "Poisonous Mushrooms groweth where old rusty iron lieth, or rotten clouts, or neere to serpents' dens or routes of trees that bring forth venomous fruit. . . . Few of them are good to be eaten, and most of them do suffocate and strangle the eater. Therefore, I give my advice unto those that love such strange and new-fangled meates to beware of licking honey among thornes, lest the sweetness of one do not counteracte the sharpnesse and pricking of the other." This was Gerarde's prudent advice on the eating of "Mushrooms and Toadstooles," but now-a-days we know better. Cowley said—

Where once such fairies dance, no Grass doth ever grow,
 and in Shakespeare's time the sheep refused to eat the Grass on the fairy-rings. I believe they now feed on it, but I have not been able to ascertain this. But as to human food, the fungologists tell us that those who refuse to eat any fungus but the Mushroom (*Agaricus campestris*) are not only foolish in rejecting most delicate luxuries, but also very wrong in wasting most excellent and nutritious food. Fungologists are great enthusiasts, and it may be well to take their prescription *cum grano salis*; but we may qualify Gerarde's advice by the well-known enthusiastic description of Dr. Badham, who certainly knew much more of fungology than Gerarde, and did not recommend to others what he had not personally tried himself. After praising the beauty of an English autumn, even in comparison with Italy, he thus concludes in his pleasant and useful book, "The Esculent Funguses of England":—"I have myself witnessed whole hundredweights of rich, wholesome diet rotting under trees, woods teeming with food, and not one hand to gather it. . . . I have, indeed, grieved when I reflected on the straitened conditions of the lower orders to see pounds innumerable of extempore beefsteaks growing on our Oaks in the shape of *Fistula Hepatica*; *Ag. fusipes*, to pickle in clusters under them; *Puffballs*, which some of our friends have not inaptly compared to sweetbread for the rich delicacy of their unassisted flavour; *Hydria*, as good as oysters, which they very much resemble in taste; *Agaricus deliciosus*, reminding us of tender lamb's kidneys; the beautiful yellow *Chautarelle*, that *kalon kagathon* of diet, growing by the bushel, and no basket but our own to pick up a few specimens in our way; the sweet nutty-flavoured *Boletus*, in vain calling himself *edulis* when there was none to believe him; the dainty *Orcella*; the *Ag. heterophyllus*, which tastes like the crawfish when grilled; the *Ag. ruber* and *Ag. virescens*, to cook in any way, and equally good in all."

Musk Roses (see Rose).

Mustard

is mentioned in a few places, but only as the condiment, and with no reference to the plant. H. N. ELLACOMBE.

(To be continued).

Phylloxera on American Vines.—M. Bontin (in *Comptes Rendus*) finds that a resinous principle exists in American Vines which have resisted the attacks of the Phylloxera, especially in the bark of the roots; that it is present in about double the proportion in which it occurs in the French Vines. He thinks the resisting power of the American Vine due to this resinous substance. The puncture made by the insect is cicatrized by the exudation of the resinous matter when this is present in sufficient quantity, and the escape of the nutritive juices of the plant is thereby prevented.

Lilium Martagon.

Dianthus dentatus hybridus.

Helianthemum pulverulentum.

Saxifraga Aizoides.

Rheum australe.

Bartonia aurea.

Mimulus cupreus hybridus.

Phloxis Samia

Gentiana cruciata.

Scilla peruviana.

Calendula officinalis fl-pl.

Ligusticum peloponesiacum.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

THE bright sunshine which we have had during the past few days has had a beneficial effect on hardy flowers, and especially on those growing in moist, rich soil. St. Bruno's Lilies (*Anthericum Liliastrum*) are just now very attractive, as are also large beds of Squills (*Scilla peruviana*, and its white-flowered variety), in Mr. Barr's grounds at Tooting. When grown in free, well-drained soil in warm situations, such as the edges of shrubby borders, the blue-flowered form of this Squill ranks amongst the choicest of June-blooming hardy plants. The handsome drooping flowers of *Hyacinthus amethystinus* are likewise now very beautiful, as are also the flame-coloured blossoms of *Delphinium nudicaule*. Feather *Hyacinths* of various kinds are now bearing large trusses of bluish Violet blossoms; Sun-roses (*Helianthemum*), too, are now laden with blooms, and, where growing on the edges of borders or on rockwork, they rank amongst the most effective flowers now in season. The bright golden blossoms of *Linum campanulatum* are being produced in abundance, as are also the long trusses of ivory-white flowers of *Saxifraga cochlearis*; the double-flowered form of the common Red Campion (*Lychnis diurna*) is laden with rosy blossoms, and the Gentian-leaved Speedwell (*Veronica gentianoides*) is also still bearing racemes of pale blue flowers. The bright purple

*Prunella grandiflora.**Helonias latifolia.*

blossoms of *Primula japonica* rank amongst the most attractive flowers now in bloom, and the yellow Bachelor's-buttons (*Ranunculus acris* fl.-pl.) may still be bought in quantity in our flower markets. Large plants of the Italian Alkanet (*Achusa italica*) are literally covered with showy blue flowers; this is a plant which deserves to be more frequently met with in shrubberies, for associated with *Periwinkle* (also in blossom), it has a fine effect, and when planted in good soil it will thrive for years if undisturbed. The bright golden-flowered *Genista prostrata* now forms one of the most effective of rock plants, or planted in hollow trees it has a very graceful appearance. In addition to the above may be found in good condition many of the *Geraniums*, *Silenes*, *Alliums*, and the white and yellow *Asphodels*. *Pinguicula grandiflora*, too, is one of the prettiest of plants for the edgings of lakes, ponds, or other moist places, its numerous dark blue flowers rendering it very ornamental. The white and blue forms of *Atragene austriaca* are furnishing great quantities of showy, Clematis-like blossoms, and when grown over heaps of dead roots, or allowed to run wild among shrubs, they are very effective. The Daisy-like flowers of *Erigeron purpureus* may also now be gathered in abundance. *Lasthenia glabrata* and *Anthemis arvensis* are likewise flowering freely; some of the *Rheums*, too, are throwing up their gigantic flower-spikes. The *Euphorbias* are not at all unattractive plants when grown in dense bushes and covered with yellow inflorescence as they can be seen at Kew; the proper place for them is, of course, in the wild garden, along with Golden Rods and Michaelmas Daisies. *Burrielia gracilis* and *Centaurea montana* are well in flower, as are also *Chelidonium majus*, and *Stylophorum diphyllum*. *Pyrethrums* of various kinds are beginning to open their China Aster-like blossoms, and the blue and purple-flowered hybrid Larkspur will soon be very attractive. Flowers of the single *Narcissus poeticus* may still be gathered, and those of the double-flowered variety are still abundant in our markets. S.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Pelargoniums.—Some autumn-struck cuttings of scarlet and pink *Pelargoniums* should now be potted for winter-flowering. Amongst the single red varieties I have found nothing better than *Vesuvius*, nor in single pinks the old sort *Christine*; both are short-jointed, compact growers, producing their flowers freely through the winter with a little warmth. The new double variety *Wonderful* (similar in habit) as a scarlet is still better, its flowers lasting longer. To prepare them for winter work they need special treatment; the first essential point is not to over-pot, the object being to have the plants in a dwarf, compact, thoroughly ripened condition, consequently the pots used should not be over 6 in. in diameter; ordinary loam, with a little rotten manure and sand, is the best material in which to grow them; press the soil quite firm in the pots, plunge them in a bed of ashes out-of-doors in a situation fully exposed to the sun, stop the shoots as necessary to induce bushy growth, pick off all flowers as soon as they are formed, give water as required; they will need nothing more until September, by which treatment the plants will be in the hard, stocky condition that enables them when placed in warmth to produce flowers freely instead of pushing off into growth. **Heliotrope.**—Some spring-struck cuttings should now be moved into 6-in. or 7-in. pots, plunged outside, kept stopped, and the flowers picked off similarly to the *Pelargonium*. This sweet-scented favourite so managed will produce flowers, with the assistance of a little warmth, all through the autumn up to the end of the year.

Pot Roses that have flowered and have now about completed their blooming should, if they require it, be moved into larger pots, but where a liberal supply of manure-water is given them, they do not need so much root-room. Any long, straggling shoots should be shortened back and the weaker wood cut away. Plants grown in this way should always be on their own roots, so that their strong sucker shoots can be retained, as these make wood that produces the finest flowers, whereas, if grafted plants be used, the shoots produced below the union with the stock will necessarily have to be removed. In potting, use good strong loam with one-fifth rotten manure and a little sand; light soil is totally unsuited for pot Rose culture. The plants should be plunged up to the rims of the pots in coal ashes in a light situation, and should not be allowed to suffer for want of water. Those that do not require potting should receive manure-water once a week; those that are potted should have it as soon as the roots get fairly hold of the soil; this treatment is essential to promote free growth, for upon the strength of the wood made through the summer in a great measure will depend their blooming capabilities the ensuing winter and spring. Previous to turning them out, see that they are perfectly free from aphides, red spider, and mildew; should any of these pests exist, dip in or syringe with Gishurst (2 oz. or 3 oz. to a gallon of water)—an infallible remedy for mildew as well as insects. There is no plant that is more deserving of attention than pot Roses, not only for the flowers they produce through the winter and spring, but also, when well managed, for their longevity, as when fairly treated they will go on improving for a dozen years or more, a single plant at that age producing as many flowers in a season as half-a-dozen newly-potted specimens.

Lilies in pots will now require more water as the soil gets full of roots, and should be placed in an open situation away from the influence of walls or trees to avoid weak and spindly growth; turn the pots round every two or three weeks to prevent the plants getting drawn to one side. The earlier-flowering kinds, such as *L. eximium*, will now be benefited by the application of manure-water. See that all are kept perfectly free from aphides, which get down into the points of the shoots on the partially developed leaves, and in a very short time cause them to become curled and permanently injured. A little Tobacco-water, syringed into the points of the affected shoots, and on the under sides of the leaves, will be found effectual in destroying them. The plants will be much better for being plunged in ashes, which will save labour by their requiring considerably less water and greatly benefit them by preventing their thick mass of roots from being affected by the sun. The earliest-flowered kinds should be staked and tied, so far as they require it, before the growth gets too far advanced.

Deutzias in pots, that were forced in the winter, and have been since kept in a Vinery or other structure where a little warmth could be added, will now have so far completed their growth as to be ready for turning out-of-doors; this is one of the few hardy plants that makes its growth for next year's flowering much better when kept inside than in the open air. A good companion to the above is the double-flowering Plum. These should also be plunged during the summer.

Chrysanthemums, that were moved a short time ago into their flowering pots, should now be plunged. It often happens that a few of the strongest shoots of these so far take the lead as to deprive the weak ones of their share of nutriment; where this is the case pinch out the points and peg them out horizontally to the sides of the pots.

Carnations and Pinks.—Winter-flowering Carnations that have ceased blooming, if desired to be kept for another year, should now be moved into pots of a larger size; all the loose soil should be removed from the ball without disturbing the roots much; they should be potted in good loam mixed with a little rotten manure, leaf-mould, and sand; drain them well, or, by being exposed through the summer to heavy rains, the soil will get in a wet, unsuitable condition for the roots; they should be plunged out-of-doors in coal-ashes, which is the best material to keep out worms. At the time they are potted some more cuttings should be taken off, putting six or eight in 4-in. or 5-in. pots in sandy soil; covered with a propagating glass shaded and kept a little warm, they will soon root, and make nice plants before autumn. Cuttings of Pinks for forcing should also be put in and potted on singly as soon as rooted; there are few plants more suitable for amateurs to grow than these winter and spring-flowering Carnations and Pinks; they are easily managed, do not occupy much room, and with a little warmth afford a succession of sweet-scented flowers alike suitable for bouquets or vase decoration. They are not much subject to insects, though green fly sometimes attacks the young leaves, its presence, however, is easily detected by the leaves beginning to curl up; dipping and syringing with Tobacco-water will be found the best remedies. The plants must always be sufficiently supplied with water, or they get into a stunted condition, from which it is difficult to induce them to emerge.

Salvia gesneræfolia.—Cuttings put in some time ago will be ready for moving into 6-in. pots. This most useful winter-flowering subject naturally assumes a bushy habit, but to furnish the plants with plenty of shoots near the base the points of the leading growths should now be pinched out. These, in like manner, ought to be at once plunged out-of-doors in a sunny, sheltered situation. It is a free grower, and makes roots rapidly. In the course of six weeks' time the plants will require moving into 10-in. or 12-in. pots for blooming, keeping them outside till the beginning of September.

The White-flowered Abutilon Boule de Neige is deserving of a place in even the most select collection of greenhouse plants. It blooms nearly during the whole year, producing in succession its beautiful drooping flowers, alike suitable for display on the plant or for cutting; it is of the easiest possible management. Cuttings of the half-ripened shoots, 5 in. or 6 in. in length, inserted singly in 60-sized pots in sand, kept moist, shaded, and covered with a propagating-glass in a little warmth, will strike in a few weeks, and make nice small specimens that will bloom through the autumn and winter. *A. vexillarium* and *A. vexillarium igneum* are equally worthy of cultivation, flowering freely in small pots with ordinary greenhouse treatment. The two latter, grown with single stems 12 in. or 18 in. in height, and then stopped so as to form a bushy head, make beautiful miniature standards suitable for table or window decoration, or for placing in the greenhouse, where if raised on inverted pots they greatly relieve the even surface of dwarf-growing subjects.

Centaureas and Coleuses.—If a few small plants of the different varieties of *Centaurea* used for bedding be placed singly in 6-in. or 7-in. pots, and grown on in a cold frame or pit, they will be found very useful for standing about in the conservatory amongst flowering plants through the autumn; they also make nice window plants, bearing confinement better than most things. A few of the most handsome-leaved *Coleuses* should now be put into pots proportionate to the required size of the plants—8-in. will be sufficiently large for general decorative purposes; they should be accommodated in a frame or pit, or they may be kept where they are to remain through the summer in the greenhouse.

Petunias and Balsams.—Petunias struck late should also be potted, tying them well out and stopping the shoots to keep them bushy. Many of the double varieties now in cultivation possess a compact habit of growth, and from their easy culture and free continuous-blooming disposition, they are very useful for greenhouse decoration during the summer and autumn. Earlier plants of these Petunias that have been flowering for some time should be assisted with manure-water and kept tied into shape, by which means they will continue blooming for some time yet. The later-sown Balsams should be moved out of the small pots they occupy into others 7 in. or 8 in. in diameter. These quick-growing, gross-feeding plants require rich soil, a light position, and a plentiful supply of water to produce them in anything like condition.

Kitchen Garden.—Another sowing of Peas should be made immediately; it will be better to put in some second early sort, as the tall late kinds after this time will do little good in most parts of the country. Continue to earth up successional sowings as they appear above ground, and stake them before they get blown about by the wind.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

June 11.—Potting *Alocasia macrorrhiza variegata* and *A. metallica*; also *Amarantus bicolor* and *A. tricolor*. Potting-off *Snowflake* *Lobelia*. Sowing American Cress, more Peas, and Chicory. Planting Cucumbers indoors, and on border French Beans that have been raised in pots. Putting in cuttings of *Chrysanthemums*, *Gloxinias*, and *Pelargoniums*. Pruning back superfluous wood on wall fruit trees, and nailing in the leading shoots. Picking the dead flowers off Azaleas and placing them in greenhouse to make their growth. Netting Gooseberry and Currant trees. Tying Lettuces. Thinning the shoots of autumn-fruiting Raspberries.

June 12.—Shaking out plants of *Aërides Fieldingi*, dividing them into small pieces, and potting them. Sowing Broad Beans, Coleworts, and Spinach between Currant bushes; also a little *Scorzonera*. Planting Asparagus, Buda Kale, and Couve Trenchuda. Pricking out Lettuce and Cauliflower plants that have been raised in boxes. Throwing out trenches in which to plant the main crops of Celery. Gathering Strawberries for preserving when perfectly dry. Top-dressing the latest-flowering Lilacs in pots with loam and manure. Thinning Pears on walls that have set too thickly so as to leave two in a bunch. Watering Dahlias with guano-water.

June 13.—Potting Cannas intended for conservatory decoration and placing them in Vinery. Shifting *Iresines* into 10-in. pots. Sowing Larkspurs in pots. Planting Pinks, Lily of the Valley, Daisies, Forget-me-Nots, Pansies, Stocks, Asters, and Winter Greens. Pegging down bedding plants in flower gardens. Layering Sir Charles Napier Strawberry. Watering border of second Vinery, in which the Grapes are just colouring. Putting coal-ashes under Orchids in pots, and slightly fumigating *Phalaenopsis* house in order to keep down thrips and other insects. Hoeing among Rhubarb crowns, and thinning shoots of Seakale Plants. Putting manure in pit ready for planting with Cucumbers. Taking up bulbs, and clipping *Cerastium tomentosum*.

June 14.—Potting *Love-lies-Bleeding*, *Tropæolum*, and *Verbenas*; also *Cattleya exoniensis* and *C. crispata*; and staking out and repotting old plants of *Bouvardias* that have been cut back. Planting a border of Veitch's Autumn Giant Cauliflower and Cottagers' Kale. Top-dressing Gardenias with a mixture of peat loam, horse-manure, and silver sand. Layering runners of Black Prince and President Strawberry. Watering Peach-house borders inside and out, giving Seakale and Parsnips a watering with guano-water, exposing Peaches that are getting ripe to the full influence of the sun, fumigating *Cattleya-house* for thrips, and preparing a bed on which to sow Lettuce and Endive.

June 15.—Potting shrubby *Calceolarias* into 10-in. pots. Sowing Egyptian Green-flesh Melons, Chicory, more Peas, Radishes, and Spinach. Layering Keen's Seedling Strawberries. Planting Sweet Peas, *Scrophularias*, *Gazanias*, and *Centaureas* in flower garden, and April-sown Lettuces on Celery ridges. Thinning and transplanting Parsley; also thinning Onions, Leeks, and seedling Seakale plants. Putting in *Gloxinia* and *Pelargonium* cuttings. Netting Cherry trees and Strawberries that are getting ripe. Collecting manure with which to make another Mushroom-bed. Sticking Peas and Scarlet Runners, and emptying and refilling Melon pits ready for planting for autumn crops. Syringing outdoor Peach trees with clear water to keep off insects.

June 16.—Potting *Petunias* for conservatory decoration; also *Fuchsias*, scarlet *Pelargoniums*, and *Heliotropes*. Shifting Melon plants just up into 4-in. pots. Planting out a few pot Roses and some April-sown Cauliflower plants and French Beans from pots; also Ice-plants. Pricking out *Cinerarias* and *Primulas*. Putting in *Chrysanthemum* and *Coleus* cuttings, and putting greenhouse plants out-of-doors. Earthing up Potatoes, Melons, and Cucumbers. Levelling laud for Winter Greens. Going over wall fruit trees and picking off curled leaves infested with insects. Thinning Carrots and Turnips, and putting short Grass between Strawberry plants. Pegging down plants in flower garden, and watering them; also watering orchard-house trees and late Vineries with manure-water.

Hardy Flowers.

AURICULAS.—The cultivator of these beautiful flowers should begin to re-pot his plants. The necessary compost is a most important matter, and it is always well that it should be prepared and kept turned occasionally, so as to get it thoroughly sweetened before using. Growers now use a plainer compost than that recommended by the late Mr. George Lightbody and other eminent cultivators of the Auricula. That employed by the Rev. F. D. Horner, our champion Auricula grower, consists of decayed turves of an old pasture that have been suffered to lie by and rot for a year or two, and which are crumbled to pieces with the hands, not sifted, in the proportion of about one-half; one-fourth of good leaf-mould, the same quantity of thoroughly decomposed manure, and some silver-sand, or, better still, some fine charcoal. Some dry cow-droppings may be used in place of the manure, but it should be previously baked in an oven to kill any insects in it. In potting, a 4½-in. pot will be quite large enough for the best plants, unless they be very strong, and a 3-in. pot for the smaller plants. A good-sized crock should be placed over the hole, then a layer of small crocks, and over this again a layer of charcoal. Auricula-pots can scarcely be too well drained, especially for delicate-growing varieties.

For re-potting, a large portion of the old soil should be shaken from the roots, and if the tap root be large, it needs to be cut away to within 1 in. or 2 in. of the leaves, according to the number of roots on it. If the soil be used moist, that is, not quite moist enough to cling to the fingers, no water need be given till the plants require it. In the state of inaction there will be ample moisture to keep the plants fresh and cool, unless dry, hot weather should set in. As soon as potted, the plants should be placed in a frame on a north aspect, and shaded from the sun. The earlier the plants are potted, the sooner do they get into active autumn growth, and this, as most of us know, has much to do with promoting the strength and general well-being of the plants.

CARNATIONS AND PICOTEES.—Now that there seems to be a promise of dry weather, care must be taken that the plants in pots do not suffer from drought; the growing flower-stems must be carefully tied out to stakes, to prevent them being snapped off by the wind. The plants are greatly benefited by top-dressing, which is generally done towards the end of the month. The compost usually employed is that made up of equal parts of yellow loam, leaf-mould, and well-decomposed manure. Some of the earlier varieties will soon require disbudding, especially if good flowers be required for exhibition purposes. Mr. E. S. Dodwell recommends that disbudding should be performed immediately the lateral buds can be removed, leaving, as a rule, the main bud and those proceeding from the third and fourth joints, counting from the top. This is assuming three flowers are to be left. Disbudding will be beneficial under any circumstances, and the remaining flowers are produced in better character. Plants in beds will be similarly benefited by a good top-dressing, and all the plants, whether in pots or beds, should be frequently syringed.

CHRYSANTHEMUMS.—Large-flowering plants, intended for specimens, should be shifted at once into their flowering pots; those 10 in. or 11 in. in width, are best. The soil must be rich, for the plants have a great deal to do in the pots, but they must be well drained.

The foliage of *Chrysanthemums* suffers as much from excessive wet as from drought. Plants that are intended to supply specimen blooms by-and-by should be potted about the end of the month; but the soil required for them need not be so rich as in the case of those for specimens. A close, short-jointed growth is what cultivators should aim at at this season of the year. If the weather set in dry, plants in the open air should be mulched with manure and syringed occasionally.

LILIUMS.—Plants growing in pots should now be fully exposed; set them along the sides of garden walks on a layer of ashes to prevent worms from working into them. In order to have plants of a general symmetrical growth they should be turned round occasionally that each side of the plants may be towards the sun. They should not be crowded, or they may become drawn. Some plants of *L. Thunbergianum* have formed their buds and will soon be in bloom. This is one of the best early-flowering varieties for pot work, and *L. longilorum* succeeds it, with *L. auratum*, *L. tigrinum*, and others in close succession. The plants are greatly benefited by a top-dressing of rich soil, piling it up a little round the rim of the pot so as to form a kind of basin for convenience in giving water.

As the plants show colour in the flower-buds they may have some manure-water once a week or ten days. If worms work in the pots a little lime-water will generally dislodge them.

VERBENAS IN BEDS.—Some have stated that the Verbena is dying out, and that the attempts to produce large and well-formed flowers have been at the expense of constitution. This is perhaps true of some of the varieties, but there are yet a number of strong-growing kinds that are very useful for bedding purposes. Beds of Verbenas of different varieties mixed together have a charming effect in the flower garden, and are to be preferred to beds of a particular variety. If the weather prove dry, the plants will need to be well watered

from time to time. There should be a top-dressing of fine, rich soil also, for the leading shoots of the Verbenas lie close to the ground, and throw out root from the joints, and if these have something to feed upon the plants are greatly helped.

VERBENAS IN POTS.—In some parts of the country Verbenas are finely grown in pots for show purposes. They are placed in the pots at this time of year in a rich soil made up of loam, leaf-mould, manure, and sand, one or two good plants in an 8-in. or 9-in. pot, with a layer of oyster-shells for drainage, having thereon about 2 in. of manure and charcoal mixed. When potted, they are placed in a cool frame to get established, and finally set on a bed of manure 6 in. in depth, with a good drainage beneath. A framework is made on which lights can be put when requisite, so as to protect the plants from heavy rains and wind. After the plants have rooted through to the manure-bed, they are not moved till required for the exhibition tent.

Indoor Fruit Department.

Peaches.—Early Peaches will have nearly completed their growth by this time, and the successful finishing of this year's crop and the prospect of the next will depend upon the treatment which the trees receive now. The fruit that is approaching maturity should

The Trophy Tomato (see p. 493).

be well exposed to the sun by pulling the foliage aside where it shades it, or by pinching it off altogether. The shoots should also be thinned out without hesitation wherever they are too thick—not in the way of shortening them back, which only encourages spray, but by cutting them clean out with the knife. Wherever the young shoots overlap each other, so to speak, they are too crowded, and nothing is gained by retaining so many. They may be tied down upon the older and naked wood which is better shaded, but nowhere should they be so crowded that the light cannot penetrate freely through and among the branches, admitting light and air to the leaves everywhere. As regards temperature, when the fruit is stoned the Peach will bear a high temperature with free ventilation and plenty of moisture at the root; but it is not desirable to subject it to a very strong heat unless time is an object. We have often run early houses up to 90° and 100° on fine days, but a temperature of from 70° to 80° when the fruit is swelling will produce the best results. Peaches that have been hard pushed are never either so large or so well-flavoured; all large and heavy fruit is grown slowly. Late Peaches should be treated like early ones, only that, as they make their growth during the summer, they need not be trained quite so thinly as the former. Peach borders are seldom made so rich or so deep as Vine borders, and, as the soil is often allowed to become very hard, it parts with its moisture more readily, consequently watering is the more necessary when the weather is dry and warm. A firm border suits the stone fruits best, but it is frequently allowed to get too dry. A good soaking of water at the beginning of the season, and a mulching on the top, will do much towards carrying the crops through the critical time, but water should be given liberally throughout the summer.

Stone Fruits in Pots.—Orchard houses, I am afraid, have not as a rule been so successful as some have been led to expect they would be. The trees usually grow and flower well enough, but getting a good set of fruit, and afterwards getting the crop safely past the stoning period, are always ticklish matters. In pruning and pinching the cultivator cannot well go wrong if he always leave a few inches of wood every time he pinches, and is careful not to perform the last operation so late in the season that shoots have not time to form leaf-buds; but in the watering and nursing of the roots he is often at fault. Alternations of heat and cold, and an irregular degree of moisture at the roots, are not conditions favourable to plant growth at any time; but in the case of orchard-house trees in pots they are often ruinous. Everything depends almost upon the watering and general treatment of the roots, from the time the trees come into flower till the fruit is stoned. The pots are usually crammed with roots, which require a large quantity of water every day in dry weather, and one day's neglect at the critical season will sometimes ruin the prospects of a crop. The pots should always be plunged in the border and mulched on the surface, and water should be given whenever the soil appears to be the least dry. The plunging and mulching keep the roots at a uniform temperature, or nearly so; whereas, when the pots are merely stood upon the surface of the border, the temperature of the soil about the roots will sometimes vary as much as 10° or 15° in twenty-four hours, according to the weather, which is simply a killing state of things. And even when plunged, the temperature will vary much, if care be not taken to use water of the temperature of the house. An open tank inside the house will usually contain water at the proper temperature, if it be allowed to stand in the tank for twenty-four hours before using, and no cold water is allowed to run in during that time. Such tanks should always be large enough to hold sufficient water for each day's supply without re-filling. This is the best guide we know of for gauging the size of hothouse tanks. The water that is run in to-day should be used to-morrow, and the tanks filled as soon as emptied.

Figs.—Figs in cold houses, and from which one crop only in the season is expected, should be trained thinly, and the shoots should neither be tied in too tightly nor be stopped. Pruning the Fig for one crop of fruit consists solely in removing a portion of the shoots when they are too crowded, leaving what remains to grow as much as they will; it is at the points of the shoots where the fruit is borne. Other culture consists in keeping the roots within bounds, in order to check exuberant growth, and giving plenty of water throughout the summer. Plants forced in pots for more than one crop should be regularly pinched at every third or fourth joint, to induce successional crops; but pinching should cease by the beginning of August or sooner, in order that the last growth may be furnished with terminal buds, otherwise the first crop the following year will be a failure. In other respects, pot trees require to be treated like the others.

Apples and Pears.—When these are grown under glass as bushes, a restrictive system of training is necessary, and consists

in simply pinching the leading shoots every 6 in. or so, and the side shoots to two or three joints; in other respects they should be treated as directed for stone fruits. It is barely needful to say that all the fruits here mentioned require plenty of air when grown under glass, but they must be guarded against cold draughts. J. S.

The Trophy Tomato.—Having tried all the kinds of Tomatoes advertised, I have come to regard the one, of which the annexed is an illustration (see p. 489), as the best for general culture, being handsome, large, without ribs or sutures, and of a bright red colour, with solid, high-flavoured flesh; if it have a fault, it consists in being too fruitful, for the flowers set in such clusters that if not timely thinned the plant literally dies from over-fruitfulness. It is a late variety; the Orangefield, growing under exactly the same conditions, ripened its fruit a fortnight earlier. This I recommend as the best early variety, and The Trophy as by far the best late sort.—W. WILD-SMITH, *Heckfield*.

STAMPING OUT INJURIOUS INSECT PESTS.

At a special meeting held on Tuesday last, at the offices of the Society of Arts, John Street, Adelphi, a paper on this subject was read by Mr. Andrew Murray, from which the following are extracts.

As to the advantage of the general principle of stamping out, and the necessity of an executive authority to direct it, there cannot be much difference of opinion, but there remains the more difficult question, how much and what kind of interference may be tolerated, and by what safeguards it should be surrounded, and how far it is workable or not? The administrative machinery by which it should be carried out need not concern us. If Government resolve to interfere, it must fall to them to make their own plans and find their own tools—but as a contribution towards elucidating the various points which they would have to consider, I think I may usefully draw the attention of the meeting to a few of the different ways in which interference might be beneficially exercised. The simplest, the most powerful, and the most efficient of these is what I may call county or district rotation of cropping. Farmers know well enough the advantage of a rotation of a cropping (or its equivalent) on their own farms. By long-continued growth of the same crop on the same land the soil becomes exhausted of some of the elements necessary for the proper development of that kind of crop, and a change of crop brings other elements into use, and relaxes the demand upon those that have been too much drawn upon. Exactly the converse of this takes place with regard to certain insects. The great majority of vegetable-feeding insects do not feed on all kinds of plants indiscriminately; most of them are restricted to one kind of plant, and if by cultivation of that plant its numbers are enormously increased, so will naturally be the number of the insects that feed upon it, while, if we should cease to grow that plant, the number of the insects would correspondingly diminish. Thus, for instance, if a district be almost entirely in pasture, there will be very few Wheat-feeding insects in it, but if it be turned into a Wheat country, they will be in myriads. If these numbers reach such a pitch as to deteriorate the crops, the remedy is plain. Change the rotation, and grow some other crop instead of Wheat. Allow me to illustrate this by an actual example. Last summer I spent the month of July at Broadstairs. In my rambles about the place I was immediately struck with the Wheat crops. At a little distance they looked tall and strong, but on examining the ears I found them only about three-quarters filled. The blade or leaf was throughout almost entirely white and dry, and I have no doubt that if I had asked any farmer what was the cause of the poor ears, he would have said drought, as shown by the bleached and dried-up leaves. And if his assumption that the bleaching of the leaves was due to drought had been true, his conclusion would have been quite right. It was the deficient action of the leaf that stayed the flow of nutriment to the ear. No fear of the farmer making any mistake upon this point. He, at least, is perfectly alive to the fact that if you want a good crop of any kind, you must have abundant and healthy foliage. Try to grow any plant, and see what kind of crop you will have if you constantly deprive it of its leaves. But although he would be quite right in describing the deficiency of weight in the ear to the failure of the leaf, he would in this instance have been wrong in ascribing the failure of the leaf to drought. It was due to the mining of the larva of a small fly named *Agromyza graminis*, which lays its eggs under the skin of the leaf at its tip. From thence the young larvæ mine downwards, feeding on the parenchyma of the leaf, leaving nothing behind them but the empty husk, consisting of the upper and under walls of the leaf. If the leaf be small, they entirely consume the interior; if large, they may not reach entirely to the bottom of it, but will have consumed about three-fourths of it before

they pass into the pupa state. Now, of course, I cannot tell what amount of damage this insect did. Had I guessed that I was likely to be now reading a paper about it, I would have got the ears dried and weighed, and endeavoured to give chapter and verse for a specified proportion. But not having done so, all that I can do is to leave those who are familiar with the subject to work it out for themselves, merely premising that almost every blade in the whole district seemed attacked. Still, for the purpose of my next point it is necessary for me to make some estimate of the proportion of loss. I have said that the ears seemed only three-quarters filled. They continued so until reaped. Let us suppose that this is too much by half, and take an eighth. This would give a loss of upwards of 12 per cent. on the grain crop, and to make the margin still wider, and the figures more manageable, let us reduce it to 10 per cent. The actual percentage of loss is not of much consequence, if I can satisfy you that it was considerable, and my object is less to show the amount lost, than where it falls.

Now we all know that the total yearly produce of a farm has to be distributed between three accounts—one is in repayment of the cost of cultivation; another is in payment of rent; and the third is the tenant's profit. It is plain that no reduction can be got either from the expenses of cultivation or the rent on account of this insect damage. The tenant or cultivator has to lose the whole of it, and you will also see that although the loss on the whole crop may only be 10 per cent., that is by no means the percentage of the loss on his profit. If, for example, we suppose that the tenant's profit on the entire produce is one-third, and that the total gross produce of the Wheat crop was £500, 10 per cent. loss on that is £50; but 10 per cent. loss on the tenant's profit would only be £16, whereas a deduction of the whole £50 would be equivalent to upwards of 30 per cent. You will thus see that this in its present stage is entirely a cultivator's question. The landlord (not a cultivator) has only a prospective interest. If arrangements could be made by which such insect damage could be annihilated, no doubt as leases terminated a readjustment of rent suited to the improved production would take place; but in the meantime it is the tenant who suffers, and who will be first benefited by stamping out such insects. Now a change of crop, if carried out over a sufficiently wide district, supplies an easy and effectual cure for the attacks of this insect. Its habits lend themselves to such a remedy. It feeds only on Wheat and a few allied pasture Grasses. At Broadstairs there were crops of Barley and crops of Wheat growing side by side, the only separation between them being a footpath, not 2 ft. in width, running through the field; and while, as I have said, every Wheat blade was ruined, I could not find one touched on the Barley. Furthermore, the insect is only an annual. If it could be banished for one year, it would be banished entirely, or until reintroduced. Now if there were a controlling authority in that district, what would be easier than to say to the farmers, "Gentlemen, in the common interest you will substitute Barley for Wheat in your next year's rotation?" The fly, deprived of its proper nidus, must then either lay its eggs in an unsuitable place where they will perish, or have recourse to the pasture fields for *Triticum repens*, or other suitable Grasses. By this, of course, the fly would not be exterminated, but its numbers would be so reduced as to render it comparatively harmless, at all events for a time, when, if it reappeared in force, the same means of defence could be again resorted to. Nay, it might be so arranged that two or more counties might brigade themselves together, so as to establish a permanent see-saw by which they should play into each other's hands. But you will observe that no single man can carry out such a rotation. He might try it upon his own fields, but they will be replenished continually from the fields of his neighbours, unless they at the same time are compelled to follow the same rotation. It is, therefore, for cultivators who know the respective capabilities of soils, and the relative returns of Wheat and Barley, to say whether they would prefer to suffer a heavy yearly percentage of loss, or to submit to the substitution of Barley or some other crop instead of Wheat for a single year. Before leaving this point let me remind the meeting that the plan of excluding for a year a particular crop from the cultivation of a district will apply to almost every crop that is grown, whenever the insect is one that does not live over one year, and this includes by far the greater number of injurious insects. The next means of extirpation to which I shall advert is burning the nidus, in which the insect, in whatever stage, passes the winter. We want some one to compel the burning of the heaps of Couch Grass and weeds gathered from foul land, instead of keeping them to rot into manure. These are the focus and shelter-place of wireworms and other pests, and contribute largely to their spread. To the same class of remedies belongs the local treatment which I recommend for the Onion fly. The plants attacked are readily distinguishable from those that have escaped—the former are sickly, flaccid, and yellow, the latter firm,

erect, and green, and those attacked can easily be picked out and burned. If these be destroyed, the whole future family is annihilated. The Carrot plants attacked by the Carrot fly are equally easily distinguished and destroyed, but it is not certain that the grubs in them keep always to the same root. But both with them and similarly destructive insects that infest the Cabbage and Turnip, a year's avoidance of that crop throughout the district will relieve it from them. Next comes the remedy, in the shape of some application that is fatal to insects. This plan is adopted in America for the destruction of the Colorado beetle, where Paris green is dusted in powder or sprinkled in solution over the larvae on the Potato plants. It is the plan used by our horticulturists to get rid of the red spider in their hothouses, where sulphur is the medium. Manufactured into Gishurst Compound, or made up into some soapy solution, sulphur is also largely used by them to destroy green fly. Sulphur has also been successfully used on a small scale against the Hop fly, and might be advantageously used on a large scale. There are various other supposed specifics (such as hellebore for the Gooseberry caterpillar, &c.) which are more or less in favour with different individuals. As a remedy, however, such applications seem better adapted for individual protection than combined stamping out, although it would be foolish to forego the advantage of using them where they seem to meet the requirements of any special case.

The following resolutions were carried:—1. That thanks are due to the President and Lords of the Council for having brought the subject of insect damage under the consideration of the agricultural bodies of the kingdom. 2. That much of the loss occasioned by insects is preventable, and ought to be prevented. 3. That it properly belongs to Government to provide the necessary means for protecting cultivators from this loss, as it is only by combined and simultaneous action over considerable districts that it can be effectually done, and Government alone possesses or can obtain the requisite means of enforcing such action. 4. That the President and Lords of the Council and the different agricultural societies throughout the kingdom be informed of the opinion of this Conference, and urged to take the subject at once into their consideration, with a view of providing a remedy.

In the course of the discussion which ensued reference was made to the Acts passed in Missouri, Kansas, and Minnesota last March, and there were several expressions of hope that they would be published in some form in this country for guidance. The Acts are given in full in the ninth annual report of the State entomologist for Missouri, and published at Jefferson City by the State printers. The Missouri Act is entitled "An Act to Encourage the Destruction of Grasshoppers." It enacts that a bounty of 5 dols. a bushel for eggs before they are hatched, or (Section 2) 1 dol. a bushel for young during March, 50 cents. during April, and 25 cents. during May, shall be paid to any person who shall gather them or cause them to be gathered. One half of the bounty shall be paid by the State and the other half by the county in which they are collected. The other sections of the Act have reference to the official reception and measuring, and forms for claiming the bounty. The main feature of the Kansas Act is that it applies to all migratory insects, and gives power to the township trustees to warn out all able-bodied males between the ages of twelve and fifty for the purpose of destroying the insects, under such direction and in such way as may seem best to the road overseers, the fine for failing to comply with the orders being 3 dols. a day. All persons over eighteen may be exempt from personal duty on paying 1 dol. a day. In another Act arrangements are made for united action through whole Senatorial districts. The Minnesota Act both enacts bounties, as in the case of the Missouri Act, and also compulsory action or fine, as in the Kansas Act.

Transplanting Young Vegetables.—I am not inclined, like your correspondent "A Northern Gardener" (see p. 431), to discontinue the practice of transplanting young vegetables from the seed-bed into another, for if the plants gain nothing by it they lose nothing. When transplants they will certainly obtain greater size and vigour by the time that they are required to be finally planted out; and, if distressed, they can be moved to where they are to be grown even in dry weather, with a larger amount of roots attached to them than when allowed to remain in the seed-bed until planting time. By transplanting, too, more time is given for clearing previous crops off the ground, which they occupy no slight advantage, especially as regards small gardens.—J. W. Llanestfan.

Blighted Pelargoniums.—All my Pelargoniums this year that have either red or pink in the petals seem to be infected with a peculiar sort of blight. Directly the flower is fully blown, spots appear, taking out all the red colouring matter from the petals, leaving a blue shade, and in a few hours the whole flower turns brown, and goes off as though it had been wetted. The white and purple Pelargoniums escape. The blooms are unusually large and fine, and the plants very healthy and free from green fly. Several people in the neighbourhood have made the same complaint about their Pelargoniums. Can any one state the cause or suggest a cure?—A. Subscriber, St. Leonard-on-Sea.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

JUNE 5.

This show, like the last, was only a small one, but the exhibits were of an unusually interesting character, especially the groups of Orchids of which the show was chiefly composed.

First-class Certificates.—These were awarded to the following new and rare plants:—

Cattleya Skinneri alba (Veitch).—A pure white-flowered form of the well-known *C. Skinneri*, with much the same habit and floriferous qualities.

Odontoglossum Alexandræ roseum (Ollerhead).—A variety with rather small but perfectly formed flowers, the lower petals of which are of a delicate rosy-lilac colour.

Aquilegia hybrida cœrulea (Douglas).—The flowers of this resemble those of the well-known *A. cœrulea*, but they are larger and of better substance; it promises to be an excellent garden variety.

Aquilegia hybrida californica (Douglas).—This has reddish-petalled, creamy-centred flowers, which are produced in abundance, and are very showy.

Pelargonium, Virgin Queen (Turner).—A show variety with large trusses of white flowers, the upper petals of which are slightly marked with rosy-purple.

Pelargonium, Venus (Turner).—A very dwarf-habited, white-flowered kind admirably adapted for decorative purposes.

Pelargonium, Mr. King (Turner).—A good habited variety, with large trusses of flowers, which have rich purplish-crimson petals and clear white centre.

Pelargonium, Eloquence (Turner).—This has rich, dark velvety flowers, the lower petals of which are bright crimson, and the centre creamy-yellow.

Pelargonium, Tom Bowling (Burley).—A Zonal raised by Mr. Postans, bearing fine trusses of soft orange-coloured blossoms of large size; well worth cultivation.

Begonia, Gloire de Nancy (Laing).—A dwarf variety having bright orange-scarlet flowers, which are double, and produced in abundance, even on small plants.

Miscellaneous Plants.—Messrs. Veitch & Sons exhibited a group of choice Orchids, amongst which we remarked finely-flowered plants of *Cattleya Mossie*, *Odontoglossum nevium*, *Saccobolium unipulacum*, a fine variety of the showy yellow-flowered *Oncidium concolor*, and the new white-flowered form of *Cattleya Skinneri*. From the same firm also came a collection of thirteen varieties of *Masdevallia*, including all the best-known kinds, as well as a few others, chiefly of botanical interest. For these a silver medal was awarded. An excellent group of Orchids also came from Mr. Ollerhead, gardener to Sir H. Peck, Bart., Wimbledon House; in this we noticed well-flowered plants of *Dendrobium giganteum*, *Odontoglossum citrosimum*, *Lælia purpurata*; a neat little plant of *Saccobolium retusum*, bearing two long, graceful spikes, thickly beset with richly-coloured, delicately-scented blossoms; and *Dendrobium amœnum*, furnished with from fifteen to twenty flower-spikes. For these a silver medal was awarded. Mr. Willis likewise showed a well-arranged group of Orchids and Ferns, intermixed. Amongst the Orchids were good examples of *Odontoglossum Alexandræ*, *Cypripedium barbatum*, and several choice varieties of *Cattleyas*. It also contained a specimen of *Anthurium Scherzerianum*, bearing over twenty large and brightly-coloured spathes. Mr. Loveland, gardener to J. G. Hepburn, Esq., Sideup, showed a group of Orchids, amongst which were excellent examples of *Odontoglossum vexillarium*. A large plant of *Anguloa Clowesi*, bearing upwards of a score of large yellow, cup-shaped blossoms, and an *Oncidium crispum*, furnished with a long branching spike, on which were nearly fifty flowers. The same exhibitor showed a few plants of the brilliant *Epidendrum vitellinum majus* in good condition, for which and the rest of the collection a silver medal was awarded. Mr. Charles Turner, Slough, showed a collection of Show and Fancy *Pelargoniums*, to the best of which allusion has already been made. Mr. Burley exhibited a group of Zonal and Variegated-leaved *Pelargoniums*, amongst which were several kinds of a meritorious character. Amongst variegated varieties the most noticeable were Mrs. J. C. Quonell, a free-growing kind, with silver-edged leaves and bright pink blossoms, and a double white-flowered sort named *Belle of the Ball*. *Azalea indica imbricata* came from Messrs. Veitch & Sons; its flowers, which are double white slightly striped with pink, closely resemble blossoms of a well-grown Balsam. Mr. B. S. Williams, Holloway, had a new Show *Pelargonium* named *Dr. Masters*, with dark, semi-double flowers, well adapted for cutting purposes. Mr. Turner showed a large, purple-flowered single *Petunia* named *Mount Beauty*, which, on account of its vigorous habit of growth and large flowers, will doubtless be much grown for covering tree stumps or heaps of stones during summer. *Juniperus virginiana variegata*, shown by Mr. E. Holmes, Whittington Nursery, Lichfield, promises to be a valuable addition to hardy Conifers. Mr. Kinghorn contributed six seedling *Gloxinias*, all distinct and worth a place in every collection. For cut blooms of *Isias*, arranged in bottles placed amongst small plants of *Pteris serrulata*, shown by Messrs. Barr & Sugden, of Covent Garden, a bronze medal was awarded. Blooms of *La France Rose* in good condition came from Mr. Iggulden,

garden to R. B. W. Baker, Esq., Ossott Hall, Essex; and Mr. Loring had cut blooms of *Prince of Orange* Plantice, large and fine. Mr. D. had exhibited large trusses of the scarlet and white Brompton Stocks, and also some flowers of *Tropæolum* and *Mimulus*. The Rev. A. Rawson sent two kinds of *Calochortus*, both of which attracted much attention.

Fruit and Vegetables.—Some good Strawberries came from Mr. Cadge, Tring Park; and Mr. Gilbert, Burghley, sent a green-flesh Melon, named *Victory of Bath*, which had a very thin, netted skin, and flesh possessing good flavour. A dish of very large, clean-looking fruit of Hathaway's Excelsior Tomato was shown by Mr. Iggulden, and was deservedly awarded a cultural commendation. Messrs. Carter & Co. contributed good heads of their Late Silverhead Broccoli; and medium-sized heads of a very white and compact Broccoli came from Mr. Gough, The Gardens, Westwood Park. A bunch of fasciated Cucumbers, four in number, from a single joint, came from Mr. F. Swanick, Whittington House.

Royal Horticultural Society's Provincial Show of 1878.—It has been decided by the Council of the Royal Horticultural Society that a great Provincial Horticultural Show shall be held in June next year, at Preston, in Lancashire, and we are informed that the needful guarantees have been secured. Mr. T. M. Shuttleworth, of Howick House, Preston, has undertaken the office of local secretary.

Royal National Tulip Society.—The annual exhibition promoted by the Royal National Tulip Society was held the other day at the Botanical Gardens, Old Trafford. The exhibition was originally announced for Whit-Friday, but a backward season made it necessary to postpone the show. About £60 was offered in prizes, and the list had attracted a large number of exhibitors. The Tulips were well arranged on a table running down the centre of the permanent exhibition house, and made a very pretty show, although an unfavourable season has left patent defects upon many of the specimens. The following is the list of the principal awards:—**Rectified Tulips**—Five stands of twelve dissimilar Tulips, 1, Mr. Whittaker, Salford; eight stands of six dissimilar Tulips, one feathered and one flamed, in each class, 1, Mr. Charles Forman, Chellaston; four stands of six dissimilar Tulips, one feathered and one flamed in each, 1, Mr. H. Housley, Stockport; six stands of three feathered Tulips, one of each class, 1, Mr. W. Whittaker; six stands of three flamed Tulips, one of each class, 1, Mr. J. Thurston, Wolverhampton; four stands of two Tulips, one feathered and one flamed, of any class, for maiden growers only, 1, Mr. H. Hill, Nottingham; six stands of two Tulips, one feathered and one flamed, of any class, 1, Mr. Whittaker; single bloom in each of the six classes, feathered Bizarres, Roses, and Byblœmens, flamed Bizarres, Roses, and Byblœmens, 1, Mr. Housley; feathered Byblœmens, 1, Mr. Whittaker; feathered Roses, 1, Mr. H. Housley; flamed Bizarres, 1, Mr. J. Turner, Stockport; flamed Byblœmens, 1, Mr. Whittaker; flamed Roses, 1, Mr. D. Woolley, Stockport; best feathered Tulip and the best flamed Tulip in the exhibition—flamed Tulip, Mr. Forman; feathered ditto, Mr. D. Barber. **Breeder Tulips**—Six stands of dissimilar Tulips, two of each class, 1, Mr. S. Barlow, Chadderton; eight stands of three Tulips, two of each class, 1, Mr. Thomas Haynes, Derby; single bloom in each of the three classes, Bizarres, Roses, and Byblœmens—Roses, 1, Mr. S. Barlow; Bizarres, 1, Mr. Barber; Byblœmens, 1, Mr. Haynes; best breeder Tulip of any class in the exhibition, Mr. S. Barlow.

QUESTIONS AND ANSWERS.

Dewdrops on Vine Leaves.—The dewdrops on Vine leaves spoken of (see p. 140) are the natural exudations of the leaves, caused by a cool, moist, confined atmosphere, which in dull weather is apt to induce damp. Ventilating freely, and at the same time using a little fire-heat in cold weather, will dissipate the moisture.—J. SMITH.

Hardy Early Pink and Purple-flowering Bedding Plants.—I should like to know of a really good bedding pink flower for spring blooming. The *Sidenes* and *Saponarias* are too late in flowering, being only just now in perfection, when the beds should be filled with their summer occupants, and pink *Daisies* seem inferior bedders compare I with the red and white. Would any of your readers name also an early-blooming purple Pansy suitable for spring beds?—M. S. H.

Bletting in Grapes.—I have some *Madresfield* Court Grapes, many of the berries of which have suddenly gone off as if scalded, although the Vine is remarkably healthy, some of the leaves measuring as much as 15 in diameter; the Vine is in a small house with Black Hamburg, Sweetwater, and Lady Downe's Seedling, none of which show any such symptoms. The temperature has been well kept up—65° in the night and 75° or 8° in the daytime. The berries, where bletted, have a dull yellow hue, and the skin and matter immediately under it are evidently dead. For any information which your readers can give me on the subject I shall feel extremely obliged.—G. E.

Treatment of Azaleas after flowering.—My Chinese *Azaleas* have now done flowering, and I wish to place them in the best positions for making vigorous new wood—the climate here is mild and the situation well sheltered from harsh weather. At present they are under glass, some in a Peach-house and others in a Vinery, both under the shade of foliage. I however, prefer the open air. Will you kindly inform me which place you consider best for the next four months?—CORK EXTRACTOR. [Keep them under glass till they have made their young wood; then turn them out-of-doors to ripen it, shading them from direct sunshine.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

THE GARDENS AT SOUTH KENSINGTON.—These are improving in aspect a good deal. Mr. Barron has made sundry changes, mainly in the way of removing the many angularities and geometrical puzzles with which the garden was at first "adorned." It is an instructive fact, in relation to the opinion concerning this garden often clearly made in our pages, that every change towards simplicity of details, every abolition of any of those whimsical old resurrections which were so very fashionable a dozen years ago has been a decided improvement. In many gardens great improvements may be made at trifling expense by the mere removal of puerile geometry, needless banks and terraces, stone-work out of place, coloured gravels, &c.

DWARF PHLOXES.—The little Phlox, which we figure this week, is one of the Rev. J. G. Nelson's seedlings. His father raised the well-known P. Nelsoni. We believe this to be not a hybrid, but a variety of P. subulata. It is probable that we shall some day have a race of these small Phloxes, as brilliant in their way as the large varieties that now grace our gardens in autumn. The kinds already raised by Mr. Nelson from P. subulata will, we hope, be increased and distributed in gardens generally.

A LILY BED.—There is now coming into flower in the grounds of the New Plant and Bulb Company, at Colchester, a bed containing five thousand plants of the handsome *Lilium Szovitzianum* figured in THE GARDEN, vol. ix., p. 201. This fact speaks eloquently of the progress made in the culture of hardy flowers within the past few years. Twelve years ago, in the height of the bedding-out fever, there was not a Lily to be seen in cultivation out-of-doors about London, even the old white Lily having been thrown away on the old rubbish-heaps to make room for the "Tom Thumbs" and "Calcies" of the period.

PRIMUMA GRANDIS.—The new Caucasian Primrose, which bears this high-sounding name, is now in bloom in the nurseries of Messrs. J. Backhouse & Son, at York. It is, so far as the flowers are concerned, the poorest of the entire genus yet seen, not to be compared for a moment with the poorest Cowslip. The flowers are borne in clusters, and are pendent and pale yellow; petals very narrow, deeply lobed, and so small that an observer, without close inspection, would never imagine that the plant was in flower at all. The foliage is ample, and to this circumstance, and perhaps the height of the flower-stem and the number of the pigmy blossoms, must the name "grandis" be attributed! Truly "all is not gold that glitters."—P.

ODONTOGLOSSUM VENTILLARIUM.—A plant of this lovely Orchid, in Mr. Williams's nursery, Holloway, is now furnished with from eight to ten long, gracefully drooping flower-spikes, each of which is laden with delicate rose-coloured blossoms of unusually large size. There are in all on this plant, which is growing in a 7-in. pot, nearly fifty blooms and buds. Plants possessing such floriferous qualities as this, and producing such magnificent blooms, cannot be too highly prized or too extensively cultivated, and when we consider that it thrives best in a cool house its value becomes greatly enhanced. —C. S.

HARDY FLOWERS IN THE BOTANIC GARDENS, BIRMINGHAM.—I was very glad to see the Moccasin-flower (*Cypripedium spectabile*) in bloom a few days ago in the Botanical Gardens, Birmingham, and though not so highly coloured as the specimen figured in THE GARDEN (see p. 254), yet the plants were well grown and the blooms of considerable size. Among other plants in bloom, the most noticeable were *Erodium absinthifolium*, *Veronica prostrata*, and *Delphinium nudicaule*. A bed of white Talips, intermixed with Forget-me-nots, likewise looked exceedingly pretty, and there was also a pure white variety of *Camassia esculenta* in flower in this garden, where, according to Mr. Latham, the curator, it has been grown for many years.—J. TREVOR.

NYMPHÆA PYGMÆA.—In your last number (see p. 471) you allude to *Nymphæa odorata*. It is many years since I have grown it or seen it, but my recollection of it is that the foliage is nearly as large as that of our native N. alba, and therefore not well adapted for growth in small suburban gardens. N. pygmæa, on the contrary, is a perfect little gem. I have an example of it in an earthenware pan, about 1 ft. in diameter and 7 in. deep, which flowers continuously from April until October, when, for convenience sake, its supply of water is reduced and the pan placed under the stage of a cool greenhouse. It always attracts the attention and admiration of all my

lady friends. There are two other plants which I much admire, but have never tried them in confined spaces, viz., *Limnorchis Hamboldti* and *Hydrocharis morsus-ranae*, the last a native plant. I also remember a friend who used to grow N. cœrulea in 4½-in. pots plunged in earthenware pans.—JOHN E. DANIEL, *The Terrace, Epsom.*

ROSE DE MEAUX.—This small Rose is now brought in small bunches in abundances to Covent Garden, where it is very pretty and very welcome. It is grown by the market gardeners.

A ROSE-COLOURED ERYTHRONIUM GIGANTEUM.—This has recently been in flower in the Edinburgh Botanic Garden. It is described to us as being in all ways like the dull yellow form, except in being a bright rose colour. It will probably prove one of the most attractive of recent additions to our choice hardy flowers.

ARBUTUS MENZIESI.—A fine specimen of this scarce North American shrub is now in flower in the York nurseries. It measures from 15 ft. to 20 ft. across, and nearly the same in height. As a hardy evergreen it is a striking and ornamental tree. The bark is deciduous; the flowers (white wax bells) are borne in dense, erect, branching, terminal clusters.—R. T.

SEEDLING ABUTILONS.—Mr. B. S. Williams, of the Victoria Nurseries, Holloway, has sent us cut flowers of two new seedling Abutilons, both of which promise to be valuable for conservatory decoration. They are said to be dwarf in habit; one, named Orange Prince, bears bright orange-red blossoms; the other, which is called Roseborum, bears flowers of a rosy-pink or salmon colour, and its bells are shorter than those of the other. These two seedlings will be found to be excellent additions to existing kinds.—S.

BROWNEA COCCINEA.—The lion of the large plant stove at Glasnevin just now is, unquestionably, this magnificent flowering shrub. We do not remember before seeing it flowering so freely, or its great, dazzling floral tassels so large and fine as they are this season. At an earlier period the specimen of B. grandiceps in the same house was also particularly showy.—B.

MASDEVALLIAS.—These are destined to effect a great change for the better in both Orchid-houses and flower-shows, judging by the beautiful and most distinct effect of a plant shown at the Royal Botanic Society's exhibition the other day by Sir Trevor Lawrence. The wondrous charm of colour and absolute novelty in form were in this case supplemented by a showy head of bloom 18 in. in diameter. When other kinds are shown in the shape of equally fine specimens, they will add a splendid change to groups of Orchids.

COCHLIOSTEMA JACOBIANUM.—A fine specimen of this plant in Mr. Williams' nursery at Holloway is now bearing ten or twelve large branching flower-spikes, each of which is furnished with numerous flowers and buds. The blossoms, which are soft velvety-purple in colour, are produced in succession for a long time, and contrast effectively with the pale salmon-coloured stalks and the broad, deep green, Agave-like foliage. This, though as yet by no means common, well deserves a place in every collection of stove plants. At Kew it has also been in flower for many weeks.

RARE HARDY FLOWERS AT COLCHESTER.—There is now a most interesting collection of hardy plants in bloom in the grounds of the New Plant and Bulb Company, at Colchester. Among them may be mentioned many of the hardy Lady's-slippers (*Cypripedium*) of North America; several of the beautiful *Calochortus* (*Mariposa Lilies*), from the sunny plains and hills of California; the white *Brodiaea*, from the same country; the beautiful little scarlet Lilies, called *Lilium tenuifolium*, *L. pulchellum*, and various other interesting plants. This and other facts speak much for what has been done for hardy plants at Colchester.

DIPLADENIAS AND IXORAS.—A fine display of *Ixoras* may now be seen in the Holloway nurseries. The plants consist of numerous varieties, even the smallest of which is laden with large trusses of blossoms. In the same house *Dipladenia hybrida* and amœna trained under the roof are flowering freely, and their large rose and white blossoms form an effective contrast with the golden, yellow, and orange-coloured flowers of the *Ixoras*. The greatest drawback belonging to both these beautiful spring and summer-flowering plants is that they require a considerable amount of heat during cold weather in order to grow them successfully. Happily, however, new kinds of equal excellence are being raised that will no doubt eventually succeed perfectly in a much cooler temperature.—S.

NEW PLANTS AT SOUTH KENSINGTON.—Mr. Charles Turner informs us that he intends sending a large collection of new *Pelargoniums* to the exhibition to be held at South Kensington on Tuesday next, the 19th inst. Mr. Wills also intends to show the whole of his new *Dracenas* on that occasion.

IBERIS PETREA.—This new perennial Candytuft, introduced about two years ago by Messrs. Backhouse, is now in full flower on the rockwork at York. It is a pretty little Alpine plant of very dwarf and tufted habit; the flower-heads are very nearly as large as those of the well-known *Iberis correæfolia*, while the whole plant is under 3 in

n height. Its great charm and distinguishing feature lies in its having rose or rose-chocolate coloured buds, which, when surrounded by the fully expanded pure white flowers, give the whole taut a pleasing effect. It thrives best when planted in well-drained but good-bodied, rather stiff loam, intermingled with small pieces of stones.—R. P.

The Fruit Crop in Kent.—With the exception of some few particular sorts the fruit crop in this district may almost be called a failure. Of early Cherries we have none, but regarding later kinds belonging to the Morello class, such as Kentish, Flemish, and Dutch Morello, prospects are more promising. Pears are nearly a blank, and the same may be said of early Plums; other kinds, including Daxsons, are very thin. Nuts promise at present to produce good crops. Apples were covered with bloom, but whether fruit will be forthcoming in proportion remains to be seen. Currants of all sorts are a heavy crop; amongst black kinds the Naples is superior to other varieties, and a heavy crop, a circumstance greatly in its favour after such a critical season as the past. Gooseberries are a good crop, with the exception of the yellow kinds, which have shed their fruit very much. Raspberries and Strawberries are blooming well, but look weakly, owing to wet and cold and absence of sunshine. Peaches and Nectarines are thin, the best are under a wide coping; other trees, not so situated, are much affected with curl and mildew. Hardy Grapes look promising, and Figs, both on walls and standards, are producing a heavy crop. Since the foregoing was written I have again examined the Apple crop, and I find that most of the fruit fall on the slightest touch; the foliage is also being shed through blight and maggot; therefore there is no chance of a full crop being harvested.—W. DYERS, *Wierton, near Maidstone.*

Fruit Prospects in Suffolk.—The wreck of the fruit crops in the eastern counties may now be said to be complete, for the Apples have followed in the wake of the Peaches, Apricots, and Plums, and all are rendered fruitless for the season. Of course there are exceptions here and there, but they merely confirm the rule, and the rule is—no superior fruit for the year 1877. The loss of the Apple crop seems a mystery to the majority of fruit cultivators. The trees flowered abnormally late, and, as I remarked on a former occasion, the blossoms seemed abnormally pale; but beyond this there was little to excite suspicion or distrust as regards the produce. Court Pendu Plat and Scarlet Nonpareil are now (June 12) in full flower; whether they will set and produce fairly abundant crops remains to be seen. Gooseberries, Currants, and Cherries are also destroyed in many localities. Walnuts are only just now coming into flower, and their extreme lateness may possibly save them, but even this is doubtful. Altogether our fruit prospects out-of-doors have not been so dreary for years past. Figs, however, seem more promising; all the earlier varieties are totally destroyed, but the later sorts are more satisfactory and promise an abundance of fruit, which this season will prove most welcome.—D. T. FISU, *Bury St. Edmunds.*

Pink and Purple Hardy Bedding Plants (see p. 492).—I can recommend nothing better or more effective as hardy pink-flowered bedding plants than the two double Daisies, Early Gem and Ranunculiflora, both of which are equal in habit and freedom of bloom to the red and white kinds. Early Gem is a large-quilled flower, the outside of the petals red and the inside white; these blending cause it to assume a bright rosy-pink hue when seen in a mass. Ranunculiflora has flat-petalled flowers slightly incurved, the back part of the petals red and the inside white; this is a robust-growing kind, and when in full bloom gives a very pleasing hue of bright pink. Earlier than these are pale red Primroses, but this particular hue is the least effective of all the coloured varieties. *Arabis rosea* is also of a pale tint, but, although free, does not produce an effective mass. It is unfortunate that we have a paucity of hardy plants suitable for bedding of the particular hue wanted. This remark also applies to purple flowers, of which we have nothing useful earlier than Pansies and Violas, and of these purple hues are the latest. The finest coloured bedding Viola of a rich purple is Mulberry, but it is a summer kind. The next best is the Terry, but this comes nearer to blue, yet so dark that it is more properly described as purple than blue. This is one of the earliest varieties, and makes a very effective spring bedding plant. The old purple Cliveden variety is still one of the earliest of the dark-flowered sorts, and one of the best. The period of flowering of Pansies and Violas is regulated by the strength of the plants, which should be got out in November to make an early spring mass of colour.—A. DEAN.

Tea Rose Exhibitions.—If we compare a grand stand of Tea Roses with one of Hybrid Perpetuals, we are struck with three peculiarities as regards the former. First, the prevalence of yellow, light and bewitching half tints in the Teas; secondly, their large, graceful,

wax-like petals, not quite so compact and symmetrical as the Perpetuals, but more artistic and picturesque in outline; and lastly, their refined and peculiar fragrance. Now to bring out these points to the greatest advantage by contrast of form and colour, also the waxy petal of the Tea with the velvet shading of the Hybrid Perpetual, as in Charles Lefebvre, Duke of Wellington, &c., would it not be well at the National Rose Show and other societies to offer some good prizes? They might, I think, be specified as follows:—For nurserymen—A stand of 24 trebles, consisting of 12 Teas and Noisettes, 12 Hybrid Perpetuals and Hybrids, three trusses of each in different stages of development, these Teas and Perpetuals to be contrasted and arranged alternately. For amateurs—A stand of 24 singles, half Teas and half Perpetuals, arranged in like manner, a Tea and a Perpetual alternately. This would ensure the brightest and most attractive stand of flowers, and be appreciated alike by Rosarians in general and Tea Rosarians. Tea Roses should not be judged by so severe a test as Hybrid Perpetuals, but while many, like Niphotes, Madame Hippolyte Jamin, and others, throw their large beautiful petals often beyond the circular line of the florist, it is indispensable for perfection that these should have high, full centres. Since writing the above I am happy to state that the Hon. and Rev. J. T. Boscawen has kindly offered to test the merits of the above suggestion by offering, as at Bath, two ten-guinea cups at the Oxford Rose Show for stands of alternate Teas and Hybrid Perpetuals; an attractive feature might be added by offering a prize for stands of the best-tinted Tea Roses, 12 blooms in variety, such as Jean Ducher, Comtesse de Nadailac, Marie Van Houtte, Homer, &c., size not to be of primary importance; this would encourage the production of these richest gems belonging to the Rose family.—H. CURTIS, *Torquay.*

Trophy Tomato.—Although the fruit of this kind resembles that of the well-known Hathaway's Excelsior when of medium size, yet when very large it assumes a coarse, irregular appearance around the pip, and on account of this well-known feature I am induced to believe that the dish of exceedingly fine fruit shown at South Kensington on the 5th inst. by Mr. Iggalden, was Trophy and not Excelsior, as in the larger fruit this feature was specially developed, whilst in the largest fruit of Excelsior this characteristic is rarely seen. I prefer Excelsior to all others, not only because it is the most productive, but also because the fruit is of good size, rich in colour, and exceedingly handsome. We only want a brisk flavour thrown into it to make it one of the best of all Tomatoes.—A. D.

Covering Early Vine Borders.—We have six early Vineries here, four of which we clear of fruit as nearly as we can by May 31; three are devoted to Black Hamburgs and one to Muscats, each being from 50 ft. to 56 ft. long; the borders are partly in and partly outside; those outside are merely protected with from 6 in. to 8 in. of dry litter (leaves where they can be had being better), and covered with wooden shutters. We commence cutting Black Hamburgs the last week in March, and Muscats the first week in May. This treatment has been carried out during these last eight seasons, and although the bunches are not so large as they were three or four years ago, still I find the comparative weight this season to be a match for that obtained in past years.—JAMES SMITH, *Waterdale.*

Grapes Bletting.—If "C. E." (see p. 492) give a little air early in the morning—say by six o'clock—or better still, leave a little on all night now the nights are warm, and allow the laterals more freedom of growth, so as to produce a little more shade over the bunches, he will find that the bletting or scalding will cease. A thin shade over the glass would be a good plan to adopt until the foliage is thicker. I have a Madresfield Court Vine here with several fruiting rods, one being trained within a few inches of the west end of the house; and about three o'clock in the afternoon, when the sun shines full upon the end of the house, I always find it necessary to shade the bunches that hang near the end glass from early in June until they are ripe, because this being a long-bunched Grape, the foliage on the roof, no matter how dense it may be, does not shade the end rod from the sun's rays when they strike obliquely against the end of the house, which they do with considerable force early in the afternoon. A narrow strip of hexagon netting will answer the purpose; or a little thin whitewash rubbed on with a brush will last the season. The Madresfield Court and Lady Downes are more subject to scalding than other kinds.—E. HORDAY.

James Veitch Strawberry.—Our late forced Strawberries have been very fine this year, especially this variety. It throws its broad trusses of flower well up above the foliage, and bears a good crop of exceptionally well coloured and finely flavoured fruits, the largest being generally of a cockscomb shape. It is also a firm fruit when ripe, and well adapted for packing, which is a great advantage. Early forced Strawberries this year did not as a rule produce crops proportionate to the size and strength of the plants, but late successional sorts have been excellent, and James Veitch above the average as regards size and quality.—JAMES GROOM, *Henham.*

TREES AND SHRUBS.

THE CUT-LEAVED WALNUT.

FREQUENTLY it happens that what may be called, from a botanical point of view, a mere variety, is of as great an importance for our gardens as the most distinct of species. In gardening the question of form is second to no other, and frequently valuable deviations from ordinary forms characterise what are called mere varieties. Thus such varieties of hardy native trees as the Weeping Wych Elm and the Weeping Beech, are more precious for the garden landscape than most new species of hardy trees; this must be clear to all who have seen these varieties in a mature state. We are, indeed, only in the beginning of our due appreciation of the value of the varieties as distinguished from the original forms of hardy trees. All interested in trees would do well to observe accidental deviations from the normal type in gardens under their care. A stray shoot or sucker showing a habit different from the type may, if separated and increased, perpetuate constantly its peculiarity. He who observes and increases it may render as great a service to the gardens of Europe as was rendered by those who secured for us the Upright Yew or the Weeping Ash. These remarks occur to us in connection with some varieties of the common Walnut as yet little known. The Cut-leaved Walnut, the subject of our sketch, merits the attention of all caring about ornamental hardy trees. The Weeping Walnut is also a new form which we recommend strongly, and which may be seen by all interested at Messrs. Lee's nursery at Isleworth. Messrs. Lee have long paid much attention to such subjects, and have a rich collection of them. The varieties of Walnut, remarkable for the peculiarities of the fruit, also deserve the attention of those growing Walnuts and whose gardens suit their growth.

Cut-leaved Walnut.

SOUTHERN INDIA.

PROFESSOR M. Williams gives some interesting notes on the vegetation of S. India in the "Times":—"With regard to plant-life, it must be borne in mind that in the creed of the Hindoos, even plants may be permeated by divinity or possessed by the souls of departed relatives. No Hindoo will cut down the divine Tulsi, or knowingly injure any other sacred plant. As to the holy Pipal, it may indulge its taste for undermining walls and houses, and even palaces and temples, with perfect impunity. Happily, there is a limit to even the most pious Hindoo's respect for plant-life. Perhaps the most demonstrative and self-asserting and at the same time most useful of tropical trees is the Palm. Palm trees are ubiquitous in Southern India, and yet the eye never wearies of their presence. One hundred and fifty different species may be seen in Ceylon, among which the most conspicuous are the Cocoa-nut, the Palmyra, the Date, the Sago, the Slender Areca, and the Sturdy Talipot—often crowned with its magnificent tuft of flowers, which it produces only once

before its decay, at the end of about half a century. Avenues of Palm trees overshadow the roads and even line the streets of towns. The next most characteristic tree of Southern India is the Banyan. The sight of a fine Banyan tree is almost worth a voyage from Southampton to Bombay, and it can only be seen in perfection in the south. One which I saw in a friend's compound at Madura was 180 yards in circumference, and was a little forest in itself. Then there is the beautiful Plantain, with its broad, smooth leaves, rivalling the Palm in luxuriance and ubiquity. Then one must go to Southern India to understand how the Lotus became the constant theme of the Indian poets, and the symbol of everything lovely, sacred, and auspicious. Space indeed would be denied me if I were to tell of groves of Mangoes and Tamarinds, clumps of enormous Bamboos, gigantic creepers in full blossom, Tree Ferns, Oranges, and Citrons, hedges of flowering Aloes, Cacti, Priokly Pears, Wild Roses, and Geraniums, or even if I were to descant at large on such useful plants as Coffee, Cinchona, Tea, and Tobacco. With regard to the last I will merely say that our thriving colony of Ceylon is the true home of the Coffee plant, and that I found Coffee-planting there in a

peculiarly flourishing condition. Nearly £6 per cwt. is now given for Coffee which formerly realized only £2 10s. The island owes much of its present prosperity to Sir William Gregory's energetic Governorship. Coffee in great quantities is also grown on the Neilgherries, the hill districts of Mysore, the Wynnad, Travancore, and the Asambhu hills. Cinchona (yielding quinine) is being cultivated with great success in Ceylon, Sikkim, and some hill stations of Southern India. As to Tea, ever since the Tea-plant was found to be indigenous in Assam and Kachar, its cultivation has gone on increasing so rapidly that it is likely to become one of the staple products of India, and will vie as an export with Rice, Opium, Cotton, and Jute. It is said that 357,000 chests were exported last year from Assam, Kachar, and Darjeeling—the three chief Tea districts—alone. The cultivation is also carried on in other hill stations of Northern and Southern India. I am told that a great future is in store for Tobacco, and that it will take the place of Opium as a source of revenue, should the Chinese demand

for the latter cease. All that is wanted is skill in its cultivation. Its success in British Burmah is remarkable.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Destroying Moss on Trees.—A writer in the London "Garden" recommends sprinkling freshly powdered lime on the Moss in damp weather, which he says will kill the Moss without injuring the trees. A better way is first to scrape off the Moss with a light hoe, or the back of a knife, and then to wash the bark with lime-wash made from fresh lime, so thin as to give slightly a white appearance when dry—that is, with a consistency half-way between lime-water and whitewash.—Albany "Country Gentleman."

A Hint.—To see the Virginian Creeper in its glory one must seek it in the Missouri bottoms, where it is not uncommon to find a dead trunk of Cottonwood or Sycamore covered from the ground to the top, 30 ft. to 70 ft. high, one grand pillar of beauty. In autumn they are really gorgeous. At the same time other trunks are twined with the Bogonia (Scarlet Trumpet-flower), one blaze of brilliant colour from base to topmost twig.—S. MILLER, Selahna, Mo., in "New York Tribune." [As the Virginian Creeper grows quite as well with us as elsewhere, there is no reason why old dead trees in Britain should not be made as beautiful as those in the "Missouri bottoms."]]

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 485).

Myrtle.

- (1) *Euphronius*. I was of late as petty to his ends
As is the morn-dew on the Myrtle-leaf
To his grand sea.
Antony and Cleopatra, act iii., sc. 12.
- (2) *Isabella*. Merciful Heaven,
Thou rather with thy sharp and sulphurous bolt
Split'st the unwedgeable and gnarled Oak
Than the soft Myrtle.
Measure for Measure, act ii., sc. 2.
- (3) Venus, with young Adonis sitting by her,
Under a Myrtle shade began to woo him.
Passionate Pilgrim.
- (4) Then sad she hasted to a Myrtle grove.
Venus and Adonis.

The Myrtle, though a most abundant shrub in the south of Europe, and though probably introduced into England before the time of Shakespeare, was only grown in a very few places, and was kept alive with difficulty, so that it was looked upon not only as a delicate and elegant rarity, but as the established emblem of refined beauty. In the Bible it is always associated with visions and representations of peacefulness and plenty, and Milton most fitly uses it in the description of our first parent's "blissful bower":—

The roofe
Of thickest covert was inwoven shade,
Laurel and Mistle, and what higher grew
Of firm and fragrant leaf.
Paradise Lost, 4.

In heathen times the Myrtle was dedicated to Venus, and from this arose the custom in mediæval times of using the flowers for bridal garlands, which thus took the place of Orange blossoms in our time.

The lover with Myrtle sprays
Adorns his crisped cresses.
Drayton.

And I will make thee beds of Roses,
And a thousand fragrant posies;
A cap of flowers and a kirtle
Embroidered o'er with leaves of Myrtle.
Rochefort's Ballads.

As a garden shrub every one will grow the Myrtle that can induce it to grow. There is no difficulty in its cultivation, provided only that the climate suits it and the climate that suits it best is the neighbourhood of the sea. Virgil describes the Myrtles as "amantes littora myrtos," and those who have seen the Myrtle as it grows on the Devonshire and Cornish coasts will recognise the truth of his description.

Nettles.

- (1) *Cordelia*. Crowned with rank Fumitor and furrow weeds,
With Harlocks, Hemlock, Nettles, Cuckoo-flowers.
King Lear, act iv., sc. 4.
- (2) *Queen*. Crow-flowers, Nettles, Daisies, and Long Purples.
Hamlet, act iv., sc. 7. (See Crow-flowers).
- (3) *Antonio*. He'd sow it with Nettle seed.
Tempest, act ii., sc. 1.
- (4) *Saturnianus*. Look for thy reward
Among the Nettles at the Elder tree.
Titus Andronicus, act ii., sc. 3.
- (5) *Sir Toby*. How now, my Nettle of India.
Twelfth Night, act ii., sc. 5.
- (6) *King Richard*. Yield stinging Nettles to my enemies.
Richard II., act iii., sc. 2.
- (7) *Hotspur*. I tell you, my Lord, out of the Nettle, danger, we pluck
this flower, safety.
1st Henry IV., act ii., sc. 3.
- (8) *Ela*. The Strawberry grows underneath the Nettle.
Henry V., act i., sc. 1.
- (9) *Cressida*. I'll spring up in his tears, an 'twere a Nettle against May.
Troilus and Cressida, act i., sc. 2.
- (10) *Menenius*. We call a Nettle but a Nettle, and
The fault of fools but folly.
Coriolanus, act i., sc. 1.
- (11) *Laertes*. Goads, Thorns, Nettles, tails of wasps.
Winter's Tale, act i., sc. 2.
- (12) *Iago*. If we will plant Nettles or sow Lettuce.
Othello, act i., sc. 3. (See Hyssop).

The Nettle needs no introduction; we are all too well acquainted with it, yet it is not altogether a weed to be despised. We have two native species (*Urtica urens* and *U. droica*) with sufficiently strong qualities, but we have a third (*U. pilulifera*) very curious in its manner of bearing its female flowers in clusters of compact little balls, which is far more virulent than either of our native species, and is said by Camden to have been introduced by the Romans to chafe their bodies when frozen by the cold of Britain. The story is probably quite apocryphal, but the plant is an alien, and only grows in a few places.

Both the Latin and English names of the plant record its qualities. *Urtica* is from *uro*, to burn; and *Nettle* is (etymologically) the same word as *needle*, and the plant is so named, not for its stinging qualities, but because at one time the Nettle supplied the chief instrument of sowing, not the instrument which holds the thread, and to which we now confine the word *needle*, but the thread itself, and very good linen it made. The poet Campbell says in one of his letters—"I have slept in Nettle sheets, and dined off a Nettle table-cloth, and I have heard my mother say that she thought Nettle cloth more durable than any other linen." It has also been used for making paper, and for both these purposes, as well as for rope-making, the Rhea fibre of the Himalaya, which is simply a gigantic Nettle (*Urtica* or *Böhmeria nivea*), is very largely cultivated. Nor is the Nettle to be despised as an article of food. In many parts of England the young shoots are boiled and much relished. In February, 1661, Pepys made the entry in his diary—"We did eat some Nettle porridge, which was made on purpose to-day for some of their coming, and was very good." Gipsies are said to cook it as an excellent vegetable, and M. Soyer tried hard, but almost in vain, to recommend it as a most dainty dish. Having so many uses, we are not surprised to find that it has at times been regularly cultivated as a garden crop, so that I have somewhere seen an account of tithe of Nettles being taken, and in the old churchwardens' account of St. Michael's, Bath, is the entry in the year 1400, "Pro urticis venditis ad Lawrenceum Bebbe, 2d."

In other points the Nettle is a most interesting plant. Microscopists find in it most beautiful objects for the microscope; etymologists value it, for it is such a favourite of butterflies and other insects that in Britain alone upwards of thirty insects feed solely on the Nettle plant, and it is one of those curious plants which mark the progress of civilization by following man wherever he goes.

But as a garden plant the only advice to be given is to keep it out of the garden by every means. In good cultivated ground it becomes a sad weed if once allowed a settlement. The Himalayan *Böhmerias*, however, are handsome, but only for their foliage, and though we cannot, perhaps, admit our roadside Dead Nettles, which, however, are much handsomer than many foreign flowers which we carefully tend and prize, yet the Austrian Dead Nettle (*Lamium Orvala*, Bot. Mag. v. 172) may be well admitted as a handsome garden plant.

Nut (see Hazel).

Nutmeg.

- (1) *Orleans*. Ho's (the horse) of the colour of the Nutmeg.
Henry V., act iii., sc. 7.
- (2) *Olown*. I must have Saffron, Mace, Date, Nutmegs.
Winter's Tale, act iv., sc. 2.
- (3) *Arnabo*. The omnipotent Mars, of lances the almighty,
Gave Hector a gift—
Dumain. A gilt Nutmeg.
Love's Labour's Lost, act v., sc. 2.

Gerarde gives a very fair description of the Nutmeg-tree under the names of *Nux moschata* or *Myristica*; but it is certain that he had not any personal knowledge of the tree, which was not introduced into England or Europe for nearly 200 years after. Shakespeare could only have known the imported Nut and the Mace which covers the Nut inside the shell, and they were imported long before his time. Chaucer speaks of it as—

Notemygge to put in ale
Whether it be moist or stale,
Or for to lay in cofre.—*Sir Thopas*.

The Nutmeg-tree (*Myristica fragrans*) is a native of Tropical India.

Oak.

- (1) *Prospero*. If thou more murmur'st, I will rend an Oak,
And peg thee in his knotty entrails.
Tempest, act i., sc. 2.
- (2) *Prospero*. To the dread rattling thunder
Have I giv'n fire, and rifted Jove's stout Oak
With his own bolt. *Ibid.*, act v., sc. 1.
- (3) *Quince*. At the Duke's Oak we meet.
Midsummer Night's Dream, act i., sc. 2.
- (4) *Benedick*. An Oak with but one green leaf on it would have answered
her.
Much Ado About Nothing, act ii., sc. 1.
- (5) *Isabella*. Thou split'st the unwedgeable and gnarled Oak.
Measure for Measure, act ii., sc. 2 (see Myrtle).
- (6) *1st Lord*. He lay along
Under an Oak, whose antique root peeps out
Upon the brook that brawls along this wood.
As You Like It, act ii., sc. 1.
- (7) *Oliver*. Under an Oak, whose boughs were Mossed with age,
And high top bald with dry antiquity.
Ibid., act iv., sc. 3.
- (8) *Paulina*. As ever Oak or stone was sound.
Winter's Tale, act ii., sc. 3.
- (9) *Messenger*. And many strokes, though with a little axe,
Hew down, and fell the hardest-timbered Oak.
3rd Henry VI., act ii., sc. 1.
- (10) *Mrs. Page*. There is an old tale goes that Herne the Hunter,
Sometime a keeper here in Windsor Forest,
Doth all the winter time at still midnight
Walk round about an Oak, with great ragged horns.
- Page*. There want not many that do fear
In deep of night to walk by this Herne's Oak.
- Mrs. Ford*. That Falstaff at that Oak shall meet with us,
Disguised like Herne, with huge horns on his head.
Merry Wives of Windsor, act iv., sc. 4.
- Fenton*. To-night at Herne's Oak. *Ibid.*, act iv. sc. 6.
- Falstaff*. Be you in the park at midnight at Herne's Oak, and you
shall see wonders. *Ibid.*, act v., sc. 1.
- Mrs. Page*. They are all couched in a pit hard by Herne's Oak.
- Mrs. Ford*. The hour draws on; to the Oak, to the Oak!
Ibid., act v., sc. 3.
- Quickly*. Till 'tis one o'clock
Our dance of custom round about the Oak
Of Herne the Hunter, let us not forget.
Ibid., act v., sc. 5.
- (11) *Timon*. That numberless upon me stuck, as leaves do
On the Oak, have with one winter's brush
Fell from the boughs, and left me open, bare
For every storm that blows.
Timon of Athens, act iv., sc. 3.
- (12) *Timon*. The Oaks bear masts, the Briers scarlet hips.—*Ibid.*
- (13) *Montano*. What ribs of Oak, when mountains melt on them,
Can hold the mortise?
Othello, act ii., sc. 1.
- (14) *Iago*. She that so young could give out such a seeming
To seal her father's eyes up close as Oak.
Ibid., act iii., sc. 3.
- (15) *Arrivagus*. To thee the Reed is as the Oak.
Cymbeline, act iv., sc. 2.
- (16) *Lear*. Oak-cleaving thunderbolts. *King Lear*, act iii., sc. 2.
- (17) *Nathaniel*. Though to myself forsworn, to thee I'll faithful prove;
Those thoughts to me were Oaks, to thee like Osiers
bowed.
Love's Labour's Lost, act iv., sc. 2.
[The same lines in the "Passionate Pilgrim."]
- (18) *Nestor*. When the splitting wind
Makes flexible the knees of knotted Oaks.
Troilus and Cressida, act i., sc. 3.
- (19) *Volumnia*. To the cruel wars I sent him, from whence he returned
his brows bound with Oak.
Coriolanus, act i., sc. 3.
- Volumnia*. He comes the third time home with the Oaken garland.
Ibid., act ii., sc. 1.
- Cominius*. He proved best man i' the field, and for his meed
Was browbound with the Oak. *Ibid.*, act ii., sc. 2.
- 2nd Senator*. The worthy fellow is our general; he is the rock, the
Oak, not to be wind-shaken. *Ibid.*, act v., sc. 2.
- Volumnia*. To charge thy sulphur with a bolt
That should but rive an Oak. *Ibid.*, act v., sc. 3.

- (20) *Casca*. I have seen tempests when the scolding winds
Have rived the knotty Oaks.
Julius Cæsar, act i., sc. 3.
- (21) *Celia*. I found him under a tree like a dropped Acorn.
Rosalind. It may well be called Jove's tree, when it drops forth
such fruit.
As You Like It, act iii., sc. 2.
- (22) *Prospero*. Thy food shall be
The fresh-brook muscels, withered roots, and husks
Wherein the Acorn cradled.
Tempest, act i., sc. 2.
- (23) *Puck*. All their elves for fear
Creep into Acorn-cups, and hide them there.
Midsummer Night's Dream, act ii., sc. 1.
- (24) *Lysander*. Get you gone, you dwarf—you bud—you Acorn!
Ibid., act iii., sc. 2.
- (25) *Posthumus*. Like a full-Acorned boar—a German one.
Cymbeline, act ii., sc. 5.

Here are several very pleasant pictures, and there is so much of historical and legendary lore gathered round the Oaks of England that it is very tempting to dwell upon them. There are the historical Oaks connected with the names of William Rufus, Queen Elizabeth, and Charles II.; there are the wonderful Oaks of Wistman's Wood (certainly the most weird and most curious wood in England, if not in Europe); there are the many passages in which our old English writers have loved to descant on the Oaks of England as the very emblems of unbroken strength and unflinching constancy; there is all the national interest which has linked the glories of the British navy with the steady and enduring growth of her Oaks; there is the wonderful picturesqueness of the great Oak plantations of the New Forest, the Forest of Dean, and other royal forests; and the equally, if not greater, picturesqueness of the English Oak as the chief ornament of great English parks; there is the scientific interest which suggested the growth of the Oak for the plan of our lighthouses, and many other interesting points. It is very tempting to stop on each and all of these, but the space is too limited, and they can all be found ably treated of and at full length in any of the many books that have been written on the English forest trees.

Oats.

- (1) *Iris*. Ceres, thou bounteous lady! thy rich leas
Of Wheat, Rye, Barley, Vetches, Oats, and Peas.
Tempest, act iv., sc. 1.
- (2) *Spring Song*. When Shepherd's pipe on Oaten straws.
Love's Labour's Lost, act v., sc. 2.
- (3) *Bottom*. Truly a peck of provender. I could munch your good dry
Oats.
Midsummer Night's Dream, act iv., sc. 1.
- (4) *Arminio*. Ay, Sir, they be ready, the Oats have eaten the horses.
Taming of Shrew, act iii., sc. 2.
- (5) *First Carrier*. Poor fellow, never joyed since the price of Oats
rose—it was the death of him.
1st Henry IV., act ii., sc. 1.
- (6) *Officer*. I cannot draw a cart, or eat dried Oats,
If it be man's work, I will do it.
King Lear, act v., sc. 3.

Shakespeare's Oats need no comment.

Olive.

- (1) *Clarence*. To whom the Heavens in thy nativity
Adjudged an Olive branch.
3rd Henry VI., act iv., sc. 6.—(see Laurel).
- (2) *Alcibiades*. Bring me into your city,
And I will use the Olive with my sword.
Timon of Athens, act v., sc. 5.
- (3) *Cæsar*. Prove this a prosperous day, the thrice-mocked world
Shall bear the Olive freely.
Antony and Cleopatra, act iv., sc. 6.
- (4) *Rosalind*. If you will know my house,
'Tis at the tuft of Olives here hard by.
As You Like It, act iii., sc. 5.
- (5) *Oliver*. Where, in the purlieus of this forest stands
A sheepcote fenced about with Olive trees.
Ibid., act iv., sc. 3.

- (6) *Viola*. I bring no overture of war, no taxation of homage; I hold
the Olive in my hand, my words are as full of peace as matter.
Twelfth Night, act i., sc. 5.
- (7) *Westmoreland*. There is not now a rebel's sword unsheathed,
But peace puts forth her Olive everywhere.
2nd Henry IV., act 4, sc. 1.
- (8) And peace proclaims Olives of endless age.
Sonnet 107.

There is no certain record by which we can determine when the Olive tree was first introduced into England. Miller gives 1648 as the earliest date he could discover, at which time it was grown in the Oxford Botanic Garden. But I have no doubt it was cultivated long before that. Parkinson knew it as an English tree in 1640, for he says:—"It flowereth in the beginning of summer in the warmer countries, but very late *with us*; the fruit ripeneth in autumn in Spain, &c., but seldom *with us*." ("Herball," 1640.) Gerard had Oleaster in his garden in 1596, which Mr. Jackson considers to have been the *Olea europea*, and with good reason, as in his account of the Olive in the "Herbal" he gives Oleaster as one of the synonyms of *Olea sylvestris*, the wilde Olive tree. But I think its introduction is of a still earlier date. In the Anglo-Saxon "Leech Book," of the tenth century, published under the direction of the Master of the Rolls, I find this prescription, "Pound Lovage and Elder rind and Oleaster, that is wild Olive tree, mix them with some clear ale and give to drink." (Book i., c. 37—Cockayne's translation). As I have never heard that the bark of the Olive tree was imported, it is only reasonable to suppose that the leeches of the day had access to the living tree. If this be so, the tree was probably imported by the Romans, which they are very likely to have done. But it seems very certain that it was in cultivation in England in Shakespeare's time, and he may have seen it growing.

But in most of the eight passages in which he names the Olive, the reference to it is mainly as the recognized emblem of peace; and it is in that aspect, and with thoughts of its touching biblical associations that we must always think of the Olive. It is the special plant of honour in the Bible, by "whose fatness they honour God and man," linked with the rescue of the one family in the ark, and with the rescue of the whole family of man in the Mount of Olives. Every passage in which it is named in the Bible tells the uniform tale of its usefulness, and the emblematical lessons it was employed to teach; but I must not dwell on them. Nor need I say how it was equally honoured by Greeks and Romans. As a plant which produced an abundant and necessary crop of fruit with little or no labour (*φύσει ἀκρίβωτον ἀνθρώπων*—*Sophocles*—non ulla est oleis cultura—*Virgil*), it was looked upon with special pride, as one of the most blessed gifts of the gods, and under the constant protection of Minerva, to whom it was thankfully dedicated.

We seldom see the Olive in English gardens, yet it is a good evergreen tree to cover a south wall, and having grown it for many years, I can say that there is no plant—except, perhaps, the Christ's Thorn—which gives such universal interest to all who see it. It is quite hardy, though the winter will often destroy the young shoots; but not even the winter of 1860 did any serious mischief, and fine old trees may occasionally be seen which attest its hardiness. There is one at Hanham Hall, near Bristol, which must be of great age. It is at least 30 ft. high, against a south wall, and has a trunk of large girth; but I have never seen it fruit or flower in England. Miller records trees at Campden House, Kensington, which, in 1719, produced a good number of fruit large enough for pickling, and other instances have been recorded lately. Perhaps if more attention were paid to the grafting, fruit would follow. The Olive has the curious property that it seems to bear a matter of indifference whether, as with other fruit, the cultivated sort is grafted on the wild one, or the wild on the cultivated one; the latter plan was certainly sometimes the custom among the Greeks and Romans, as we know from St. Paul (Romans xi., 16–25) and other writers, and it is sometimes the custom now. There are a great number of varieties of the cultivated Olive, as of other cultivated fruit.

One reason why the Olive is not more grown as a garden tree is that it is a tree very little admired by most travellers. Yet this is entirely a matter of taste, and some of the greatest

authorities are loud in its praises as a picturesque tree. One short extract from Ruskin's account of the tree will suffice, though the whole description is well worth reading. "The Olive (he says) is one of the most characteristic and beautiful features of all southern scenery. . . . What the Elm and the Oak are to England, the Olive is to Italy. . . . It had been well for painters to have felt and seen the Olive tree, to have loved it for Christ's sake . . . to have loved it even to the heavy dimness of its delicate foliage, subdued and faint of hue, as if the ashes of the Gethsemane agony had been cast upon it for ever; and to have traced line by line the gnarled writhing of its intricate branches, and the pointed network of its light and narrow leaves, inlaid on the blue field of the sky, and the small, rosy-white stars of its spring blossoming, and the heads of sable fruit scattered by autumn along its topmost boughs—the right, in Israel, of the stranger, the fatherless, and the widow—and, more than all, the softness of the mantle, silver-grey, and tender, like the down on a bird's breast, with which far away it veils the undulation of the mountains."—"Stones of Venice," vol. iii., p. 176).

H. N. ELLACOMBE.

(To be continued).

Ivy on High Walls.—In some cases a green screen may be desirable far above the ground-line; and in connection with buildings it can easily be formed of Irish Ivy planted in deep boxes of rich

light earth or in a trough formed of stone or cement, as in such positions the effect of the Ivy is all the more telling from its contrast with the large expanse of stone. The particular screen of which the annexed is an engraving was formed about 20 ft. above the ground, and in a position where it could not be planted in the earth. If it be a question only of getting Ivy high enough, it will grow to a very great height from the ground, but frequently it happens that it cannot be so planted; besides, it may be desirable to have a high surface covered, and that beneath it bare.

Phœnix rupicola.—This is one of the most graceful amongst the smaller Palms, and in form takes a place among Phœnices similar to that which *Cocos Weddelliana* takes among the species of *Cocos*. In habit it is stemless, with wide arching leaves, having a slender midrib. They are broadly lance-shaped in outline, with long narrow pinnae, the lower of which become gradually reduced to spines. The pinnae are channelled at the base, and appear to be attached by the folded base which joins on to the winged rachis, the wings being pressed together along the spaces between the pinnae and continued into the lamina. Some of the lower pinnae and spines are set on in contiguous pairs. It comes from India, and is a most valuable acquisition for collections of ornamental plants, amongst which it will occupy one of the foremost positions. It is figured (see opposite page) from plants growing in Mr. W. Bull's nursery, Chelsea.

Birds' Nests in Hothouses.—We recently noticed in the gardens of S. Ralls, Esq., Cleveland House, Clapham Park, a sight worthy of the pencil of Mr. Harrison Weir. During the present year a robin built his nest in a specimen of *Erica depressa* which was growing in the greenhouse, and there reared its young, which left the nest the day before the plant was taken to the Crystal Palace Show. The parent birds then found access to the stove and built another nest on the surface of the pot of a flowering specimen of *Nepenthes Hookeriana*. In this nest eggs were laid, but just before they were hatched the bird was found dead in the nest. The nest and eggs remain, and the *Nepenthes*, which has several pitchers, certainly loses none of its attractiveness by the novel addition of the robin's nest and eggs.—"Journal of Horticulture."

Coal Oil v. Rabbits.—Mr. W. Riehl gives to "Colman's Rural World" a statement of his success in copiously using coal oil on his trees, on a former occasion, for keeping off rabbits. He says "it worked like a charm, no rabbit ever having touched the trees since"—as rabbits have no fancy for dead trees.

THE INDOOR GARDEN.

AZALEA INDICA.

CONSIDERED in a decorative point of view, the Azalea is without exception the most useful of all cultivated plants, as it forces readily, flowers freely in a large or small state, and affords an endless variety of brilliant colours, in addition to which it will bear as much or more hard usage than any other hard-wooded subject with which we have to deal. Were it not for

really worth keeping. This is more particularly the case where seed is taken indiscriminately, and care is not taken previously to the fertilization of the flowers to remove the anthers as soon as they can be got at, and to isolate the plants operated upon to prevent the wind, bees, or other agency from interfering with the work. Unless this be done, little dependence can be placed on effecting a cross between any particular varieties from which it may be desirable to breed, and disappointment generally ensues; but with the above precautions, and the swelling and ripening of the pods, success is a cer-

Phœnix rupicola (see p. 498).

the aid afforded by Azaleas from January to June, the exhibition tables at our horticultural shows could not be made anything like so attractive as they now are, and both greenhouses and conservatories would lack their principal ornaments if some of the many beautiful varieties did not find a place therein. Though great improvement has been made in Azaleas during the last few years, hybridizers do not appear to have devoted so much attention to them as to many other subjects, and this is probably owing to the length of time between the sowing of the seed and the blooming of the plants, also to the great number of inferior kinds in proportion to those that are

tainty, as they could not reach that stage if the foreign pollen had not taken effect. In endeavouring to raise new kinds, only the very best of the old ones should be selected as parents, such as have well-formed flowers of great substance, with the petals regular and bold in outline. Having chosen the plant it is intended to make the seed-parent, and prepared the way by removing the anthers as the blooms expand, the next process is to introduce the ripe pollen from any others of opposite colours, which may readily be effected by taking the flower between the finger and thumb, and lightly touching the ends of the anthers against the pistil, the glutinous matter adhering

to which will secure sufficient pollen to fertilize the ovary, which after a few days will begin to swell, and continue to do so till the pod commences to ripen. What is wanted in Azaleas is more doubles, as they are by far the most lasting and useful in a cut state, although they are not perhaps so showy and attractive on the plants as the single flowers, the beautiful outline of which is perfection. As there are so few of the former, there is a fine field open to those who may be disposed to commence such an absorbingly interesting occupation; and as whites are much in request for bouquets and other purposes, I would suggest that Flag of Truce and The Bride should be made use of as two of the most likely to produce a good hybrid.

Seed-sowing and Propagation.

The seed should be gathered when ripe, and stored away in the pods in some dry place till February or March, when it will be time to rub it out and sow it. This should be done in properly prepared pans filled with a mixture of fibry peat and silver sand pressed firmly in, with the surface made as level and smooth as possible. After this is done, and before sowing, the proper way is to give a gentle watering through a fine-rosed watering-pot, and in sufficient quantity to moisten the whole of the soil, so as to obviate the necessity of having to use more till the plants make their appearance, as, owing to the exceedingly fine nature of the seed, watering cannot easily be done without washing or disturbing it. All the covering they will require is a sprinkling of very fine sand, and in order to maintain a uniform state of moisture and assist germination, the best plan is to lay a piece of glass over the pan, and on that some Moss or brown paper to exclude the light and prevent any fluctuation in temperature. A moist stove or intermediate-house is the most suitable place for the pans and as a nursery for the plants till they are large enough to prick out into others, or in pots or boxes, in either of which they will thrive better than if potted separately, till they become strong and require more room, as owing to the greater body of soil they are not so likely to become dry and checked in growth. As the object is to flower them as soon as possible, the plants should not be stopped, but allowed to grow till they are proved, when any desirable kind may be propagated and increased either by cuttings or grafts; the former is the easiest and most certain method, except with those skilled in grafting, as that is the quickest way of getting plants up to a flowering size, and worked stock is preferred by many, as they are not so likely to send up suckers, and are more manageable in regard to training, &c. In propagating from cuttings the young wood should be in a semi-ripe state, and about 3 in. in length, and if this be taken and trimmed in the ordinary way by removing the two lower leaves, and the base cut away with a keen-edged knife close up to the bottom joint, there will be no difficulty in striking them if they receive proper attention afterwards. The best way is to insert each close around the edge of $\frac{1}{2}$ -in. or 6-in. pots, and range them clear of each other. Cuttings so inserted always do much better than if in larger pots, where they are more distributed over the soil, the reason of which is that the porous nature of the earthenware absorbs any superabundant moisture, and gives it out slowly, thereby keeping them in a uniform condition. The proper soil is a sharp sandy peat covered with $\frac{1}{2}$ in. of clean silver sand, which should be well watered to settle it about the cuttings; the pots should be plunged in others two sizes larger, and the interstice between filled up with sawdust, sand, or Moss, on which the bell-glass used for covering up the cuttings should be placed. By plunging them in this way several useful purposes are served, as it conserves and regulates the heat and prevents the air acting directly on the outsides of the pots in which the cuttings are placed. Stage them in any stove or intermediate-house till they root, and if they can be accommodated with a little bottom-heat all the better, but that is not a matter of great importance if they have an outer pot as above to protect them, and the temperature range between 75° and 80° . When rooted, they should be gradually inured to more air by tilting the bell-glasses, and after a week or so they will bear their removal altogether, and will be in a fit condition for potting. This should be done in fibry peat in 3-in. pots, when they must

again be placed where they can have a brisk moist heat to give them a start, and afterwards be treated in the same manner as flowering plants, to which I will presently allude.

Raising Seedlings.

In raising seedlings there is a double advantage, as any inferior kinds may be used for stocks, but, in doing this, only such as are healthy and vigorous-growing should be chosen, and to fit them for the purpose it will be necessary to train them up with clean, straight stems, varying from 6 in. to 12 in. high, near the tops of which the grafts should be attached. This operation is best effected by simply slicing a piece about $1\frac{1}{2}$ in. long from the side of the stock, a little deeper than the bark, and, having taken a corresponding piece from the scion, the two should be tied tightly together with soft Esparto Grass matting or worsted, and then covered by rubbing a little wet clay or grafting wax to exclude air and light from the wound. The best place to put them after this is done is in a close propagating box or frame, with a moist heat of 75° or so, in which they will soon unite, and the proper time for carrying out the operation is in spring, just as they commence to grow, as then they callus more readily. As soon as they are united and become firmly attached, the ligatures should be removed, or they will damage the plants. In grafting, I ought to have remarked that the stocks should not be beheaded, but left to grow on to draw the sap till the scion has effected a union, when it must be cut away just above the graft, in order to divert the sap into it. Any one following out the above instructions cannot fail in propagating Azaleas to their entire satisfaction.

General Cultivation.

In regard to the general cultivation of these plants, any that it is desired to get up to a useful flowering size as quickly as possible should at once receive a shift into larger pots, and be placed where they can obtain a little shade with gentle moist heat to urge them on. In potting make choice of good, tough, fibry peat, and see that it is in proper condition for use, which is rather on the dry side than otherwise, as then it will admit of being rammed firmly around the old balls without danger of rendering it close and pasty. Some growers recommend loam with the peat, but I am of opinion that they do much better without it or any other admixture whatever, except a sufficient quantity of sharp silver sand to keep the soil open and porous. As Azaleas require liberal supplies of water when growing, efficient drainage is the first consideration, but this should in no case be carried to excess, as from 1 in. to $1\frac{1}{2}$ in. of finely-broken crocks is ample, and all beyond that is needless and occupies room that should contain food for the roots. It often occurs in potting plants of this class that the ball is dry in the middle, and when that is the case it is seldom, if ever, it can be properly wetted through afterwards, and therefore if any doubt exist as to their condition in this respect, it is advisable to immerse them for a few hours previously in a tub of water, afterwards standing them to drain. By this treatment, and keeping the balls in a healthy, moist state before potting, the necessity of watering before they get hold of the fresh soil is obviated, which is a great advantage, as it is otherwise apt to become sour from the repeated requisite wettings for the plants. In order to keep them in a free-growing state during the summer they should be shut up early in the afternoon and have a good, heavy syringing, so as to wet both the upper and under portions of foliage. As the object is to fill the pots with roots, and to develop the plant in a short space of time, the flower-buds ought to be nipped out, when the shoots will start again; but in no case should any of these be stopped, unless they appear unduly strong and are robbing the remainder, and even in that case it is better to bend them down so as to check the flow of sap and divert it elsewhere, for with a frame or foundation thus laid it is an easy matter to furnish or fill it up after. By the end of September discontinue the syringing, and keep the plants in a temperature of about 40° by night till the beginning of March, when the same course of treatment may be again pursued till the plants have obtained the desired size.

Treatment after Flowering.

In respect to old plants that have now discontinued flowering the first thing to be done is to pick off all the seed-pods except those wanted for ripening. Small and unimportant as these may appear, there is nothing so exhausting to them as seed-bearing, and therefore it is of the greatest importance that they should be removed immediately the flowers fall, that the whole energies of the plants may be concentrated on the growth of young wood and in the production of bloom-buds.

This may appear an extreme measure to adopt, but Azaleas do not resent it in the least, indeed, after they have attained a certain age, and under the above conditions, they are considerably benefited thereby, and with such treatment old plants may be kept for many years in perfect health and vigour. When this course is adopted it should be done early in the season, just as they begin to grow, when the formation of fresh root fibre and young wood and foliage will go on simultaneously. After this treatment keep the plants heavily syringed

Araucaria Goldieana (see p. 502).

In the case of those already in pots as large as it is desirable to have them, they may be greatly assisted by giving them an occasional watering with weak liquid manure made from the droppings of deer, sheep, or cows; but whenever this is used it must be perfectly clear, or it will seal up the surface of the soil and render it impervious to air, which will soon throw the plants out of health. Another way of limiting the size of the plants to the pots and keeping them in good condition after they have exhausted the soil is to cut away a good portion of the old ball equally all round and repot in the same size again.

and shaded, and in a house where they can be kept close for a time till they fairly start. It is surprising the amount of heat Azaleas will stand and enjoy while making their growth and setting their flower-buds, provided the moisture they receive is in proportion, and it is from lack of these two essentials that we so frequently see the flowers so diminutive in size, as the buds do not receive the proper amount of assistance to develop them fully before winter sets in. This being the case, they should be kept under glass and treated in the same manner as to water, syringing, &c., as those that have had

their balls reduced, till the end of July, or even later if the buds do not appear well up, after which they may be ranged in some sheltered place out-of-doors, where they can be shaded by a tree or tall-growing shrubs for a few hours during the hottest part of the day. There they will enjoy the genial night dews and ripen up their growth better than if they remain the entire season in a house; but when out-of-doors there are two things to be guarded against, viz., continued heavy rains that often set in towards the autumn, and dryness at the roots, caused by the hot air acting on the sides of the pots. The first may be guarded against by leaning the plants on their sides, and the second by putting them in a pot a size larger than the one in which they are growing, and by frequent examinations as to their condition, making sure at all times to give them sufficient water when they require it to thoroughly soak the whole of the ball. S. D.

Goldie s Araucaria (A. Goldiana).—This very handsome species is intermediate between *A. elegans* and *A. Rulei*, but superior to both, having the majestic growth of the latter and the distinct leaf of the former. The leaves are dark green in colour, varying in size according to age, while the branches, as will be seen on p. 501, are quite pendulous. It will form a beautiful object both for the decoration of the conservatory and dinner-table. Good examples of it may now be seen in Mr. B. S. Williams' nursery at Holloway.

Pelargonium Queen of Stripes.—

Amongst the most decorative varieties in the large-flowered *Pelargoniums* must be ranked the beautiful forms of bluish-white with rich carmine-rose flakes and bars, which may very appropriately be termed *Carnation-striped*. The one here named attracted great notice and much admiration when exhibited by the Rev. A. Rawson before the Floral Committee of the Royal Horticultural Society at South Kensington, and was awarded the highest certificate of merit in testimony of its superior character to any hitherto known in its class. Its growth is neat and compact, and the bloom rises well above the foliage. The flowers are produced in compact and ample trusses of six or eight blossoms in each, of good outline and substance; the ground colour is elegant bluish-white, the petals being finely striped or barred with carmine-rose, each of the upper ones being marked with crimson lines surmounted with an intense crimson blotch.—H. [A truss of this *Pelargonium*, which we have seen, fully bears out this description.]

River Scene in a Park.—This shows a river flowing beside a park in which various attempts at small lakes have been made, while, for the most part, the fine opportunities offered by the river have not been taken advantage of. Wherever a garden or park possesses natural advantages of this kind, it is well to develop them, and make no attempt whatever at artificial water. Lake-like reaches, islets, effective planting, turf-margined bays, and every feature that makes water charming, may be easily secured in such a case far more readily than in the case of purely artificial water.

Fern-fronds Green and Lasting.—I am pleased to see *Asplenium Adiantum nigrum* now used for bouquets in Covent Garden Market. It has a capital green colour, and stands well. Considering how plentiful it is in some parts of Southern England, it is amusing to learn that the fronds shown to me came from Nice.—W. T. T.

PLATE LXXVIII.

THE DWARF PHLOXES.

(WITH A COLOURED FIGURE OF A VARIETY OF *P. SUBULATA*).

Drawn by H. NOEL HUMPHREYS.

AMONGST the Phloxes are several distinct types which differ in habit and time of blooming, but they retain in a well-marked manner the general structural characters upon which the genus was established. Thus we have a group of dwarf, trailing plants—all essentially early spring bloomers—and admirably adapted for the rock garden; and we have the tall autumn Phloxes which constitute one of the most effective types of plants belonging to the herbaceous border, and which have received such attention at the hands of hybridizers that in point of variation their name is legion. Besides these two there is an intermediate group of comparatively dwarf border plants represented by *P. carolina*, *P. suffruticosa*, and others rarely met with in cultivation now-a-days. To the first of these groups the plant here illustrated belongs:

The Awl-leaved Phlox (*P. subulata*) of which that figured is a very distinct form, is one with which most plant cultivators are

familiar. It is a dwarf, trailing plant with close-jointed stems densely covered with narrow-pointed, somewhat fleshy, opposite leaves. The flowers, which are produced in such abundance in April and May as almost to cover the entire plant, are of a pale pink colour with a tendency to deepen in tint round the mouth of the short tube of the corolla. They are about half the size of those represented by the accompanying illustration. It is a native of the mountainous regions in the Southern States of America, the New World being the home of the entire genus without any exception. Besides the variety of *P. subulata* here figured, which may possibly be that recorded in books under the title of *P. subulata* var. *oculata*, we have one with pure white flowers sometimes

confounded with the following species, but nevertheless perfectly distinct.

The Snowy Phlox (*P. nivalis*).—This is of equally proeminent habit to the preceding, also of smaller growth; the leaves are shorter and more densely arranged; the flowers are of snow-white purity. Its specific title has therefore a double significance, being alike expressive of the appearance which its flowers present, and of the locality which it affects—near the snow-line of the Rocky Mountains.

Nelson's Hybrid Phlox (*P. Nelsoni*).—This is no doubt a hybrid between the two foregoing species, possessing an intermediate character as regards foliage, and along with the pure white flowers of the latter its beauty is enhanced by retaining the charming pink eye of the former.

The Bristly Phlox (*P. setacea*).—Though a close relation to the preceding as a species, this is amply distinct, its leaves are longer, more distinctly linear rather than subulate, and arranged further apart on its trailing stems than they are in *P. subulata*, and the whole plant is less hard and rigid in its texture. The flowers, which are of a charming soft rosy-pink, have delicate markings at the mouth of the tube. Besides the original, we have a handsome variety that originated in Scotland distinguished by a greater laxity of growth, and also a much deeper tint of colour almost approaching a crimson; this is known as *P. setacea violacea*: both are lovely plants and desirable ones for rockwork, where, with the roots deeply seated among

River Scene in a Park.

AN ALPINE PHLOX P. SUBULATA - VAR.

the fissures in the enjoyment of coolness and moisture, the plant is enabled to sustain and thrive luxuriantly in any amount of sunshine.

The Leafy Trailing Phlox (*P. frondosa*).—This, though possibly a garden name, and not one recognised by botanists as representing a distinct species—is, for all cultural purposes, distinct, and readily recognised from any of the preceding. In growth it is decidedly the most vigorous of the section to which it belongs, and along with the trailing habit and long leaves of the preceding species we have a fleshy character somewhat similar to that of *P. subulata*; in fact, the plant might not unfittingly be referred to a large variety of that species, and perhaps it would be almost better to substitute the title of *P. subulata maxima* in lieu of its garden *soubriquet*, *P. frondosa*. So vigorous is its growth that it makes an admirable plant for the front rank of a sunny herbaceous border, where in any ordinary light garden soil it will trail in a few years so as to cover almost a square yard of surface. Its trailing branches are rendered more massive-looking by the formation of a dense rosette of leaves, an abbreviated stem, in fact, in the axil of each of the older leaves; hence arises the foliaceous character from which its specific name was derived.

P. Douglasi and **P. bifida** belong to this setaceous section, and are good, distinct species, though by no means so showy as those just enumerated; the former has very fleshy, densely arranged leaves and mauve-coloured flowers, and was introduced some thirty years ago amongst seeds from the higher regions of the Rocky Mountains; the latter is a singular-looking woody plant, with long trailing stems, it is of recent introduction, but is rarely met with in cultivation. Besides the foregoing, there is another quite distinct trailing group with broad, more or less ovate leaves, of which the old *P. ovata*, with its variety *P. Listoni*, may be taken as a type. It includes *P. reptans*, equally well known as *P. stolonifera*, and *P. verua*; also *P. divaricata* and *P. canadensis*.

So closely allied are the foregoing species that the cultural remarks which apply to one will equally apply to all. Well-drained ordinary garden soil, with a good sunny exposure, constitute the necessary elements of success. Though perfectly hardy and unaffected by even extreme frosts, they cannot endure the damp atmosphere of mild winters such as the past has been, the result being large patches of decay, if not the absolute death of the plants. None of these species seed freely, and their increase must be by means of cuttings or by layers; the former require very careful manipulation, as they are liable to break off just above the node or joint to which the leaves are attached, thus completely neutralizing the chance of success. A sharp knife and a careful hand will soon remove the two or three pairs of leaves with their included buds without damaging either the slender stem or joint; and these, when taken off in July, when the branches are just commencing to harden, and inserted in sandy soil in a frame where they can be shaded from full sunshine, and given the benefit of the night dews by the removal of the lights, will soon root and become good flowering plants the following season. Where large patches are growing, the readiest mode of increase is sprinkling sandy soil over the entire plant and working the same gently amongst the branches with the hand. If this be done during the summer or early in autumn, the trailing branches will be found to have formed roots, and may be readily removed and planted elsewhere the following season. By this means well-established plants are formed at once; but where numbers are required, increase by means of cuttings is preferable.

J. C. NIVEN.

Botanic Gardens, Hull.

Attar of Roses.—Klissoura in Bulgaria has long been celebrated for the manufacture of Attar of Roses. During the recent warfare the stills, called *kezans*, were all destroyed, but the consequent distress of the natives has been relieved by Lady Strangford by supplying them with 110 new *kezans*.

The Banyan Tree and the Temple.—The power of the pendent root of the Banyan has been lately exhibited in the celebrated Temple of Juggernaut. The sacred edifice, which for seven centuries defied the elements and encroachments of age, is now found to be on the brink of destruction. The seeds of the Banyan tree have got under the foundations, and the whole fabric has been loosened. The ruin was first indicated by the falling of some large stones just after the idols had left the temple on the last car festival. This catastrophe has, as may be imagined, caused great consternation, and is likely to have a disastrous effect on the prestige of the Juggernaut. It is a curious coincidence that the most celebrated Hindoo temple should have been thus undermined by trees held sacred, if not divine, by the whole Hindoo nation. In the ruins of Palenque, Copan, and Uxmal (in Central America) many travellers have beheld, and the pencil of Catherwood has portrayed, the havoc wrought by the huge trees which have established themselves among the ledges and cornices of temples and pyramids reared by races which are now extinct.

THE FRUIT GARDEN.

UPRIGHT PEAR TREES.

THE accompanying woodcut represents the simplest and best form of tree for rapidly covering walls with choice Pears. Before this and like forms the old horizontal pattern, which took so many years to form, must die out. Among the many advantages that belong to the upright form may be mentioned that of simple training. To establish such trees, all that need be done is to take a young five or seven-branched tree and place the branches as near as may be in the desired position to ascend. It is not even necessary to have the

Upright Pear Tree.

branches opposite, as without that the wall may be perfectly covered. With trees of this kind a very few years' growth will suffice to cover a wall that would not be covered in sixteen years by the old method.

V.

SUMMER CULTURE OF HARDY FRUITS.

Strawberries.—A good display of blossom on the Strawberry quarter, even after it has escaped the frosts, is not always a guarantee of a good crop, if the summer culture of the plants be neglected. The weight of crop very much depends upon watering, mulching, and manuring, particularly in dry seasons, even though the ground may have been well enriched when prepared at the beginning. A mulching of half-rotten stable manure, or, in its absence, decayed bedded manure or similar material should be applied now, if not already done, covering the ground between the rows 2 in. or 3 in. deep, and well up to the collars of the plants. This will keep the ground uniformly moist, and at the same time render the placing of straw between the rows unnecessary, as the rain washes the mulching quite clean, and it serves the same end. Should manure not be available for mulching, short Grass may be used, and plenty of it; as, in the course of the summer, a thin layer of it soon shrivels up and vanishes. We prefer, in our case, to delay mulching till the flower-scapes are up fairly, or even until the fruit is set in tolerably moist seasons, as, when manure is put on, we find it stimulates the foliage too much, at the expense of the flowers; but in our thin soil a mulching of some kind is indispensable, and in light or sandy soils it is the only way of insuring well-swelled fruit. Before the mulching is applied to them the ground should be hoed and cleaned, and, if it be dry, also watered, and then mulched at once. When fresh plantations have to be formed in autumn, a year is just saved by layering the runners in good time, and keeping them stopped beyond the layer. Perhaps the very finest fruit for size and quality is obtained from plants that have been layered early in the season and planted the previous August; and when plantations have to be made, it is just as easy to give the plants some sort of preparation as not. With this object, a ridge of good soil should be laid between the rows, and the runners

laid on it; and when well rooted, they should be at once transplanted—by August at the latest. There has been much dispute concerning the practice still in force in some parts of cutting the foliage off the plants after they have done bearing, in order to encourage a later growth. Theoretically, the practice seems wrong; but it is a fact that some of the best cultivators adopt it. Probably it succeeds better in some parts than in others. In late districts the practice is not to be recommended, as the second growth of leaves and crowns has not time to mature; but in early seasons, or in early localities, we think it is advisable to cut the oldest leaves off to let the light into the crowns. It is a noticeable fact that the first growth of leaves is always tall and rank, and that when they are cut away about July the second growth is short and stocky, the leaves broad, and the crowns prominent, like plants grown in pots for forcing; and in such cases the plants invariably bear well. Plants that have been forced in pots and afterwards planted out, make their growth during August and September, and have also the same squat habit, never making a rank growth; yet it is well known that they invariably bear enormously. It is proverbial that such plants never miss a crop. The cutting-over process may therefore be recommended when the crop is soon over, and the foliage old and rusty by mid-summer; but the operator should be careful not to cut too close to the crowns.

Small Fruits.—The practice of digging, either with the spade or the fork, among Gooseberry and Currant bushes during the summer, is to be condemned. Nothing deeper than a push hoe should come upon the ground. All are benefited by thick mulchings, especially the Red Currant, which is more subject to honeydew than the others in dry seasons; and the mulching, by keeping the roots moist and encouraging growth, keeps it off. The Red Currant usually makes a very profuse growth, and the trees are much benefited by summer pruning, which consists in removing the suckers which spring from the base of the plants, usually very abundantly, and in shortening the side-shoots of the main limbs something in the same way as bush Pear trees. Gooseberry bushes are also benefited by similar treatment; but Black Currant bushes, unless it is to thin out the shoots, may be left alone till the winter pruning. Raspberries only need a good mulching and abundance of water at the roots when the fruit is swelling; the weakest of the young canes should also be removed to give the others room, five or six being sufficient at a stool.

Fruit Trees.—The grand point in the culture of all fruit trees is to provide a successional growth of bearing shoots or spurs. Beginning with wall trees, and taking the Apricot first, the chief points of summer culture consist in disbudding in good time, so as never to allow the shoots to get crowded and smother each other, and afterwards in keeping the front or fore-right shoots regularly pinched at every two or three joints, and laying in leading shoots wherever they may be needed to cover the wall. The Apricot produces its fruit on the shoots of the previous year's growth, and also on spurs along the branches, and both should be assiduously cared for and encouraged as above directed. The roots prefer a rather firm and well-drained soil, but require, nevertheless, an abundant supply of water during the fruiting season. Much of the rain which falls upon sloping borders of a hard texture runs off, and they are often drier than is imagined. They should therefore be either slightly forked over or mulched to prevent evaporation, and when the summer is dry well watered. We have seen trees on the open wall absolutely flagging for want of water under such circumstances, which is very injurious to the trees. Dryness at the root means the starvation of the present crop and the failure of the next.

Peaches.—With these the main thing is to keep the shoots as thinly and regularly distributed as possible. They should first be allowed to make a good growth, and then be laid in loosely, keeping the fruit always well exposed to the sun from the commencement. The root treatment is the same as for the Apricot, only as the Peach is more subject to insects, red spider particularly, mulching and watering is of even more consequence in its case, and is far more effectual than the syringe or insecticides in keeping down these pests. Mildew, however, must be destroyed by sulphur dusted on the leaves or applied by the syringe, or some of the antidotes for that disease may be tried; the "Mildew Composition" has a good name.

Plums and Cherries.—These should be treated, as regards pinching and training, like the Apricot, keeping them spurred in in fronts, and letting the terminal shoots which are laid in extend as much as they will, except such as are getting the lead too much, which should be stopped. Watering and mulching are highly beneficial, as both the Cherry and Plum root near the surface of the ground.

Bush and Pyramid Trees.—Apples and Pears on dwarf stocks require little more attention than the thinning out of the shoots and pinching the lateral ones on the main limbs, so as to admit the light freely among the branches and keep the trees in shape; but rigid formality is to be avoided. The natural bush shape is as good as any, and quite as ornamental, while it affords the greatest facilities for extending the bearing capacity of the trees. The terminal shoots of the main limbs should not be stopped at all, except when very strong, or when necessary to retain the balance among the branches. Shoots that are allowed to grow always furnish the most fruit-buds. The directions also apply to trees on the natural stock, when these are trained or pruned; but the orchard is the place for them, and there thinning the branches out occasionally is all that is needed. J. S.

STRAWBERRY CULTURE.

I HAVE heard of Strawberries having done badly in the open ground this winter owing to the excessive wetness of the soil, but the complaint is, I believe, local. My own plants, and those growing near me, are marvellously full of flower; indeed, I have never seen a better show on all kinds. I have a plantation of tall-planted runners of last year of the following sorts, viz., President, Le Gros Sucré, Héricart de Thury, James Veitch, Lucas, Sir Joseph Paxton, Amateur, Empress Eugénie, Dr. Hogg, Frogmore Late Pine, Premier, and Mr. Radclyffe, in all about 1500 plants, and it speaks well for their blooming qualities that only a few weak plants out of the entire number are without good trusses of flower. I have just been looking over about 2000 plants in pots at the Grove Vineyard, Feltham, consisting of Héricart de Thury, President, and Sir Charles Napier, and Mr. Cole stated that not only did not a single plant prove blind, but further that he had to remove a great quantity of bloom. Mr. Cole grows his plants in small 8½ in. pots, and the crops produced are of the most satisfactory kind. Notwithstanding the many plants that have been put forward as the best as regards planting out permanent plantations of Strawberries, I should like to add my own. Where there is a good stock runners of any particular sort can always be had in abundance, therefore when the ground is prepared, instead of planting in rows at 24 in. or 30 in. with the object of putting in a crop of Onions or Dwarf Beans between the rows the first year, plant at once good selected runners in rows 12 in. apart every way. The first year, if the runners be good and got out early, that is, directly after a crop of early Potatoes or Peas, there will be a good gathering of valuable medium-sized fruit that will make a good paying crop. Then, directly the fruit is gathered, cut out every other line of plants; fork or horse-hoe 12 in. in width between the rows, and leave space for the runners to give stock. Directly enough of these are rooted, lift them, and clear away all useless runners, and again horse-hoe lightly or use the hand-hoe deeply; then add a good dressing of long stable-manure, and allow that to remain, and if needed add long refuse straw in the spring before the fruit is ripe. After the gathering of the second year's crop, cut out every other plant in the rows, and thus for the third year's fruiting the plants will have 24 in. each way. As by that time, if the ground be good and the plants have done well, the shoots should be from 15 in. to 16 in. over, it is evident that the space given will be none too much. The third season the same treatment should be given, and after that crops taken off the plants should be cleared off, the soil broken up deeply, and cropped for two or three years with vegetables before being again laid down with Strawberries. To keep up a good succession it will be necessary to plant out one-third of the required ground to be under fruit every year, and should a partial failure result to one portion, the others will prove useful supporters. From what I have seen of the mischief done to the crowns of the plants by the laborers and women when taking off the vegetable crops, I believe that much more harm is done to the Strawberries than the other crops repay. A. D.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Synonyms.—In Mr. O. Thomas's (of Metz) catalogues of fruits, there are nearly 10,000 synonyms enumerated. The May Duke Cherry has over sixty appellations; Pear Doyenné d'Hiver, fifty-six; and Catillac, sixty-eight. Frankenthal (Black Hamburg) grape has fifty-five; and Chasselas de Fontainebleau (Royal Muscadine), forty-one synonyms.

A New Enemy of the Vine.—In a paper addressed to the Academy of Sciences, M. Schenetzler calls attention to a new Vine disease, which seems to be spreading over Switzerland, Germany, Savoy, and other parts of France. It consists of mycelia (threads) of Mushrooms, that invade all the underground parts of the plant, causing in a short time the decay of the branches, the withering of the leaves, and ultimately the death of the whole stock.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Acacias and Cytisus.—Acacia Drommoudi and *A. armata* are the two best varieties for pot culture, as when placed in a little heat, they can be brought into flower early in the winter; they are very suitable for amateurs, being easy of growth, and not liable to die off suddenly through either a superabundance or scarcity of water like many hard-wooded plants. Young plants of these Acacias that have been grown on from a small state, and others that are larger, and have been cut back and repotted after blooming, will, in most cases, have made sufficient growth, and should be exposed in the open air; this is necessary to fully harden and mature the growth, and to induce the formation of flowers, for if the plants be kept under glass in a growing state all the summer, they will not produce flowers in such profusion as if thus exposed. By getting them out-of-doors in good time, they will be in a condition to bloom earlier through the winter. The very useful winter-blooming *Cytisus racemosus superbus*, which is much better than the common *C. racemosus*, requires to be similarly treated: if a few examples of this free, delicate, yellow-flowering plant be grown, a succession of its highly fragrant flowers may be had through the winter.

Boronia serrulata is another highly fragrant subject, as a small plant in a 6-in. pot will fill a large house with perfume. Any one with a moderate knowledge of general plant-growing may venture to cultivate it, as it is not liable to die off; it is of dwarf, compact habit, and grows freely in sandy peat; when it has ceased flowering, cut back the shoots to within 6 in. of where it was stopped last year; if this be omitted, the plant soon gets into a straggling condition. It should be kept in the greenhouse for some time yet, exposed to full light, and syringed overhead every afternoon; this treatment is necessary, in order to keep down red spider, a pest to which it is somewhat liable.

Daphne indica, the most general favourite of all sweet-scented, hard-wooded plants, should, if possible, be kept on growing in a pit where a little closer atmosphere than that of an ordinary greenhouse is maintained, or it may be placed on the front shelf of a late Vinery, as the warm, moist atmosphere produced by syringing and closing the house early in the afternoon will completely answer its requirements; so treated it will make double the amount of growth that it would in a greenhouse, which is so far an advantage that it admits of more of the flowers being cut than when the plant makes less progress, although, under no conditions, should too many shoots be removed when in bloom. This plant ought never to be exposed to the open air, as from its spare, somewhat delicate-rooted nature, it suffers if the soil become too wet by exposure to rains. As generally seen, it is of medium growth, and even by those whose glass accommodation is limited half-a-dozen plants will not be too many to grow, and by keeping a portion through the winter a little warmer than others a long succession of flowers may be secured. It is essential never to overpot or overwater it.

Nerium splendens (the Oleander).—Both the pink and white varieties of the Oleander are amongst the best plants that amateurs with even a small greenhouse can grow; their beautiful Carnation-like flowers are produced freely on even small plants in 6-in. pots when the growth has been fully matured; this latter qualification is requisite, or they will fail to bloom. I should recommend amateurs who attempt their cultivation to strike a few every spring; they will root as freely as Willows with ordinary cutting treatment. Plants will bloom freely the ensuing summer, if they be struck in the spring, the leading shoots stopped, kept on growing in a greenhouse or Vinery through the summer, and the amount of water reduced in the winter, moved into 6-in. or 7-in. pots the following spring, grown under glass until midsummer, and then turned out in the full sun for the remainder of the season. Any one possessing a large plant with a number of shoots, may turn it out-of-doors any time during this month, where it will be under the full influence of the sun, through July and August, keeping it somewhat dry at the root, so as to check growth, and then take off the top shoots about 8 in. or 9 in. in length, inserting them in small pots, and putting them where they can have a little bottom-heat to assist the formation of roots, at the same time keeping the top as cool as possible to retard top growth; in a short time the shoots will become established plants. Give them ordinary greenhouse treatment through the winter, and they will bloom plentifully the following summer, and can be brought in earlier by subjecting them to the temperature of a warm pit or mid-season Vinery; plants treated in this latter way are confined to a single shoot. After blooming cut them down to within 6 in. of the pot, and as soon as they have started give them pots an inch or two larger, and encourage growth, after which submit them to a hardening process out-of-doors in the sun. If required the plants may be

grown to a very large size, but it is not desirable, even where there is ample room, as they are more useful in a small state, and from their extremely easy propagation, by a little forethought, young stock can always be obtained in succession, consequently it is better to discard them after the second season's blooming. They succeed best in loam, having a greater disposition to flower in it than in peat.

Pleroma elegans is another easily-grown, hard-wooded plant, suitable for amateurs, producing freely its unapproachable deep purple flowers. Like the foregoing, it strikes as freely as a *Verbena* from the half-ripened shoots put in about the present time; they are best struck singly in small pots drained and filled with a mixture of sifted loam, peat, and sand, kept moist covered with a bell-glass, shaded and placed on an ordinary hotbed. They will root in a few weeks, after which they may be fully exposed, the points of the shoots pinched out to induce them to break, and subjected to greenhouse treatment for a couple of years, in the second summer of which they should be placed out-of-doors in the open air at the shady side of a tree or wall that will prevent the sun in the middle of the day shining upon their leaves, which are somewhat impatient of its direct influence. As they require more room move them on into 8-in. or 10-in. pots; so treated they will bloom from almost every shoot, producing flowers which in colour are not equalled by anything in cultivation. The above are a few hard-wooded plants particularly adapted for amateurs to grow, and will be found an acceptable addition to the other occupants of the greenhouse, which too often consist of comparatively little besides *Fuchsias*, *Pelargoniums*, *Cinerarias*, *Calceolarias*, and other soft-wooded subjects, which, however beautiful in their way, do not afford much variety.

Kitchen Garden.—Almost all spring-sown vegetables are, through the extremely backward weather we have had, at least a fortnight behind ordinary seasons; for if the seeds were sown at the usual time, they either failed to grow, or made such slow progress as to be much later in attaining sufficient size to plant out. Those who are desirous of growing a full crop of Brussels Sprouts should at once plant them out where they are to be grown. From their naturally erect habit it is not necessary to allow them nearly so much room as the more spreading Brassicas, but they must not be overcrowded or they will not be able to withstand a hard winter. This vegetable, which requires a long season to attain its full size, cannot this year be expected to grow so large as usual, yet I should not recommend their being planted nearer than 2 ft. apart each way, and where the soil is very rich and naturally well suited to the requirements of the Cabbage tribe, an additional 3 in. or 4 in. will be better. A sufficient breadth of spring-sown Cabbages should also be planted, giving them room according to their kinds, small varieties, such as *Cocoa-nut* or *Little Pixie*, will do if they be placed 15 in. apart each way, whereas those of the *Enfield Market* class should stand 18 in. asunder in the rows with 2 ft. between. Savoys should have a similar space allotted to them, according to the small or large variety grown. A few spring-sown Red Cabbages should also be planted 18 in. from plant to plant, and the rows 20 in. apart. Autumn-flowering Broccoli should also now be put out at about 2 ft. to 2½ ft. apart, if intended to come into use before Christmas; the later kinds for winter and spring should be placed 3 ft. asunder each way: so grown they will bear a much more severe winter than if less space be allotted them. With the large number of amateurs who cannot find room for all the above crops until something that has preceded them is cleared off, there is no chance but keeping the plants until the required space is at liberty in the nursery beds in which they were recommended to be pricked out a short time ago, from which they can be removed with very much less check than if allowed to remain in the seed-bed until permanently planted.

Celery.—The main crop of Celery may now be planted, choosing the first favourable opportunity when the weather is showery, for although the plants may not be so large as to be taking any harm in the nursery bed, they will receive less check from moving than if planted later when they are bigger; treat as to water as recommended for the earliest planted.

Town Manure.—The Corporation of Manchester last year commenced a system of converting the city refuse into a concentrated manure which is sold in the Corporation yard at 12s. 6d. per ton. The yard extends to about three acres, and into it is collected all the refuse and offal of the town. The cinders are separated from the ashes and serve as fuel for the steam engines engaged in the manufacture of the manure. A quantity of fine ash is first separated by sieves or riddles from the dry refuse brought to the yard. This powdery ash acts as an absorbent of the more valuable fertilising articles. Of decayed fish alone an average of about 8 tons are lodged in the yard every week. A little gypsum is used to fix the ammoniacal gases. About 70 tons per week are thus manufactured.—“Manchester Paper.”

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

June 18.—Shifting *Caladiums*, *Baleams*, *Amarantus*, and *Coleus* into larger pots; potting young *Primulas*, and placing them in a cold frame where they can be kept close until established. Sowing *Champion of England* and *Nonpareil Peas*, and *French Beans*; also *Legg's Melon*, *London Coleworts*, and *Incomparable Cabbage*. Planting *Asparagus* and some *April-sown Lettuces*; also planting *Celery* in trenches for main crop, and another batch of *Cauliflowers* and *Convo Tronchuda*. Putting in *Lavender* cuttings out-of-doors under a hand-light. Fertilizing *Melons* as fast as they show flower. Thinning *Onions*, *Carrots*, and other root crops.

June 19.—Potting *Stocks*, *Asters*, *Alyssums*, *Lobelias*, and *Calceolarias* for room and conservatory decoration, and shifting *Odon-*

June 21.—Shifting *Chrysanthemums* into their flowering-pots; also *Achimenes*. Repotting *Odontoglossum Halli* and *Epidendrum bicornutum*. Sowing *Negro Long-pod French Beans* and a little *Parsley*. Planting *Endive*, *Lettuce*, *Melons*, and *Gourds*; also *Celery* and *April-sown Cabbage*, and making up vacancies among *Winter Greens*. Cleaning *Cattleyas* and *Odontoglossums*. Top-dressing *Fig trees* in pots with rotten manure. Tying up *Carnation flowers*. Thinning *Turnips* and stopping *Vines*. Hosing between all growing crops, and watering recently-planted *Celery*, *Cauliflowers*, and *French Beans*.

June 22.—Potting seedling *Cyclamens*, and placing them in heat; also potting some *Violets* and *Lobelias* for indoor decoration. Sowing *Mignonette* in pots; also *Melons* and *Cucumbers*. Planting land just cleared of early *Peas* with *Snow's White* and *Cooling's Matchless Broccoli*, and setting *Neapolitan Cabbage Lettuces* on *Celery ridges*. Putting *Poinsettias* in heat to induce them to pro-

The Garden of Plants in Old Times (see p. 569).

toglossum vexillatum and *Phloxopsida*. Sowing *Syon House Cucumber*, *Chicory*, and *American Cress*. Planting *Scotch Kale*, *Pear-nought Cabbage*, *Savoys*, *Broccoli*, and *Vegetable Marrows*. Watering outdoor *Strawberries* that are swelling their fruit thoroughly, and afterwards covering the ground with short *Grass*, in order to keep the fruit clean. Nailing in shoots of wall trees, and removing all curly leaves infested with insects. Pegging down *Tropaeolums* and *Verbenas*, and staking up *Pyrethrum* flowers.

June 20.—Potting *Zinnias*, *Dianthus*, and *Celosias*, and shifting large *Heliotropes* into 10-in. pots. Potting *Musk plants* for autumn use; also *Lady Plymouth Pelargoniums*. Baskets *Oncidium splendidum* and top-dressing *Lycasto Skinneri alba*. Sowing *Shilling's Queen* and *Atkins' Matchless Cabbage*, and various kinds of *Endive*, *Lettuce*, and *Radishes*; also *Golden Ball* and *American Red-top Turnip*. Thinning *Apples*, *Pears*, and *Plums*, and watering *Apricot trees* and all the flower garden beds that are very dry. Putting in cuttings of *Show Pelargoniums* and *Mimulus* in frames, and layering *British Queen Strawberry runners* for next year's forcing.

duce a supply of cuttings. Examining *Peach trees* carefully for green fly, and sulphuring hot-water pipes in *Vineries* to ward off red spider. Syringing *Ferns* to wash off thrips, and putting paraffin on *Apple trees* to kill *American bug*.

June 23.—Blocking *Cattleya superba*. Putting *Masdevallia Veitchi* and *M. coccinea* into 6-in. pots, and basketing *Oncidium cheiroporum*, using as soil sandy peat and broken crocks. Planting out *Spiraeas*; also *Veitch's Autumn Giant Cauliflower*. Taking up *Hyalacinths*. Netting *Cherries* that are ripening, also *Strawberries*. Digging out trenches in which to plant *Cauliflowers*, and manning others intended for *Celery*. Plunging out-of-doors large plants of *Dicentra (Dielytra) spectabilis* that have been used for forcing.

Hardy Flowers.

ASTERS.—Daily waterings at the roots must be given, and sprinklings overhead morning and evening while the present hot weather lasts. Mulchings of well-decomposed manure broken up small will be found of great service, as much depends on the plants getting a good start.

COLUMBINES.—*Aquilegia cœrulea* is now in bloom in my garden; my plants of it were grown from seed, and they are all true to character. The seed was sown in the spring of 1876, and the plants potted as soon as large enough, kept in the greenhouse all the winter, and turned out into the open border early in May. The plants will be lifted early in September, repotted, and wintered as before. *A. canadensis* is a very attractive form with red flowers, which are in marked contrast to those of *A. cœrulea*, which are bluish, violet, and white. *A. glandulosa* is remarkably handsome, and has been well described as one of the most beautiful of Alpine perennials, but it requires such careful management, and so many have failed with it, that it cannot be recommended for general cultivation. *A. Skinneri* is another fine species, the flowers red, the tips golden-yellow. *A.*

do the plants much good. Those who grow Pansies in the hotter districts of the south frequently find them die off suddenly; on examination it will be found that a kind of black rot affects the stalk near the ground and passes along the shoots, and so deadly is its action that not only does the plant quickly decay, but the shoots, if made into cuttings, rarely if ever strike. Those who use Pansies and Violas for bedding purposes should, as far as possible, select examples of a close, tufty growth, as they are generally of vigorous habit; the shoots cover the ground, which is thus kept cool about the roots. Now is a good time to put in cuttings made of the young growths sent up from the roots. My bed is made up of leaf-mould, some fine loam, and very fine cinder ashes, and it is under a north wall and raised some 12 in. above the surface of the ground. In

Dracena Goldieana (see p. 50).

caryophylloides, a very fine striped variety of the common Columbine, is charmingly effective when true to character, and a mixed packet of seed will be certain to yield some fine varieties. The seeds should be sown without delay, and the seedlings carefully tended, so that they may grow strong by the autumn.

CANDYTUFTS.—The evergreen Candytufts are useful for covering steep banks of rockwork. At Slate Hill House, near Manchester, they are much used for this purpose. They root into crevices where the soil is always cool and moist, and where, in full bloom, they make a most effective display. *Iberis sempervirens* and *I. corifolia* are both used for this purpose.

PANSIES AND VIOLAS.—This is a trying time for these, especially in exposed places where the soil is open. Top-dressing should be resorted to in order that the surface soil may be rendered fine and rich for the young roots. Sprinklings overhead in the evenings

such a bed I find the cuttings strike quickly. Pansies like a gritty soil in which their roots can run freely.

RANUNCULUSES.—In the north of England, owing to the great rainfall of the winter, which considerably deferred *Ranunculus* planting, the beds are not yet in flower, and, indeed, not throwing up their blooming stalks. A mixture of sand and manure is put on the surface of the beds to keep the soil cool and moist. It is very rarely indeed that a good bed of named *Ranunculuses* is seen in the south of England; but in the north it is a much more frequent occurrence. It is to be regretted that this beautiful flower is not more generally grown.

SPARAXIS.—A few days ago I saw in the neighbourhood of Manchester some pans of these in fine bloom. There were about twenty bulbs in a pan planted in a sandy soil, in which peat and leaf-mould had been plentifully used, and the pans had been in a cold house in

which Lilies, Chrysanthemums, &c., are grown all the winter. *Ixias*, *Colochortus*, *Babiana*s, &c., are grown in a similar way, and are very effective.

TROLLIUS EUROPEUS.—In the cool midland districts I have recently

Garden by M. André.—We gave a plan of an English garden by our first garden designer—Mr. Marnock—last week; this, one laid out by M. André, who has deservedly a high rank among landscape gardeners on the Continent. The difference between the two

Design for a Garden, by M. André.

seen this grand hardy plant in fine condition. An Oldham botanist, who is incessantly searching for new plants in that district, some time since found a form of *T. europæus* with deep orange flowers; it is a remarkably fine variety, but it is unfortunately as yet very scarce.

D.

schools will be sufficiently apparent to those who compare the plans. We may add that M. André, like ourselves, has the highest admiration for the best examples of Mr. Marnock's work, and, in conversation with the writer, lately remarked, "We have nothing in its way so good as Oak Lodge!"

THE MANAGEMENT OF CELERY.

SUCCESS in the culture of Celery may be said to consist in producing vigorous growth, without letting the plants go to seed, or bolt, to use the common term, and the whole efforts of the cultivator are usually directed to these ends, from the sowing of the seed till growth is finished at the end of the season. This success is secured by never allowing the plants to suffer a check, and we shall endeavour to point out how it may be best accomplished.

SOWING THE SEED.—Celery raised in a high temperature, and afterwards pricked out in a cold frame, and finally planted outside, is almost sure to run to seed before it is half grown, and this is entirely owing to the check received by the plants when young. The seed should be sown in fine rich soil, and it may be treated to a temperature of 60°, or less, till it comes up; after which it should be removed to a temperature of 55°, and it should never be allowed to become dry at the root, but be kept continually moist, for Celery is a moisture-loving plant. This advice of course applies to early-sown Celery; later crops can be sown in frames or sheltered places, where the plants can remain till planted out; but as a rule the main crop has to be sown early, under artificial conditions, and the above precautions are necessary. The consequence of keeping the seedlings in strong heat is that they get very long and drawn, and will not bear transplanting with safety. In a temperature of 55° they will not be overdrawn; but they must, nevertheless, be pricked out into a frame or under handlights as soon as they have made their first rough leaves. With a view to their final and safe removal to the trenches, the soil in the frame should not be too deep, otherwise many of the best roots will be lost in lifting, which may be followed by bolting soon after. Our plan is to lay 4 in. of good red soil upon a smooth, hard bottom and prick the plant into it. The roots cannot penetrate the bottom, and when the plants are taken up they come away with the balls of earth almost intact. The plants being in rows, a knife is just run along between them to sever the lateral roots, and the balls are then free. Next to these precautions in the nursery bed, water in abundance should be given, and the temperature should be high enough to keep the plants growing very steadily.

PLANTING THE TRENCHES.—These must first be prepared; whether they are wide enough to hold two or more rows does not matter very much. Those who want large heads had better, perhaps, be contented with two rows to a trench; and those who are short of room, or who prefer small heads, may have as many as six rows. Either way the trenches be well enriched with some kind of loose and quite rotten manure. Decayed leaves mixed with farmyard manure makes an excellent compost; so does the refuse material of old Mushroom beds, while cow manure rotted to blackness is the best of any. The trenches having been taken out, a dry day should be chosen for digging in the manure, and it should be thoroughly incorporated with the soil to the depth of the spade, and not simply buried at the bottom. Then the plants should be brought and planted at the same time, allowing each plant about a square foot of space to itself, and watering all thoroughly when done, and afterwards mulching the trenches with 2 in. of short Grass or rotten leaves. The advantages of mulching can hardly be over-estimated. In dry seasons it is hardly possible to keep the plants as moist at the roots as they ought to be, but mulch them thickly enough, and the soil will retain its moisture for a long while, and much labour in watering will be saved.

EARTHING UP.—Before commencing operations the soil about the roots must be examined, and if dry, it must be well deluged with water. This is a somewhat important point, as when the soil is filled in upon a dry bed it never afterwards gets properly soaked; therefore, be sure to water before earthing up, if there be the least need for it. Cultivators differ in opinion about the time to begin earthing up. As a rule, it is best to let the plants make a fair growth, and then to earth up at the rate of 4 in. at a time, but less than this rather than more, if anything. All suckers should be first removed from the collars of the plants, and the leaves should be closed in methodically and held tightly to the plants while the soil is being filled in about them. At the last operation the tops of the plants should just be left above the soil to keep up the vitality; but if hurried altogether, they will soon rot.

WINTER PROTECTION.—Unless some pains are taken to protect Celery in winter, the loss will be very serious, especially if the weather be wet. During the past winter the losses of growers were enormous, and they were particularly felt by market gardeners. We were made aware of cases in which the loss from rotting of the hearts amounted to nearly 80 per cent. Probably it would not be too much to put the loss, in private gardens, down generally at 40 or 50 per cent. after the new year. Be this as it may, all losses represent labour and material thrown away; and the question is how to prevent it, and the answer is, keep the ridges dry, keep off rain after the

plants cease growing and frost sets in. For this purpose nothing is better than light, ridge-shaped, wooden covers, which can be lifted off and on; for the cure is as bad as the disease when the shutters are left on always. About the end of November they will come into requisition, and from then till the Celery has ceased growing they should be used, and will form a defence against rain and snow, and severe frosts.—“Field.”

Planting Asparagus.—In the successful treatment of this important crop much depends upon giving the young plants a good start; in fact, if the seedling or one-year-old plants be roughly used, either in transit or removal, there will be little advance as regards time on the use of seeds instead of plants, as the ultimate progress will be all in favour of the untransplanted seedlings. I have followed the system advocated by “S. J.” (p. 453), viz., of planting one-year-old plants after they have made a considerable amount of top growth, and I find that we have fewer failures than formerly, when we used to plant immediately any signs of growth were observable. This is, however, not practicable, unless the plants are grown on the spot. We have lately planted three large beds, which were trenched 3 ft. deep, after which a heavy dressing of road-scrappings was spread on the surface; deep drills were then drawn, and the plants transferred to them at once and covered with a good coating of the same kind of sharp grit, as I find on lifting crowns for forcing that they are sounder and fuller of healthy fibres than when covered with close adhesive soil. The tops are now as vigorous as if they had not been removed, so little do they appear to have felt the check. We have for the last five years sown a small quantity of Conover’s Colossal Asparagus, and certainly the produce is finer than that which we used to cut. This I attribute partly to the variety and partly to improved culture, for even old beds of any variety may be induced to yield finer produce by encouraging and protecting the top growth after cutting is discontinued, by liberal top-dressings, and applications of liquid, and by avoiding needless mutilation of the roots.—JAMES GROOM, *Henham*.

The Garden of Plants in Old Times.—Through all the years which this establishment has existed it never appears to have had the least charm of natural beauty or simplicity. Here it is in old days as formal, barren, and uninteresting, as far as one may judge from an old engraving on p. 506, as it is at present. In all these old pictures of gardens it may readily be seen how far those who designed them were from having a single notion of the meaning of garden design. It is wall designing, walk-designing, canal-designing, &c., anything but garden design. That art was born when the first informal garden was formed or tolerated, though all the charms it has in store for us have yet to be realised one by one.

Dracæna Goldieana (see p. 507).—This fine, ornamental-foliaged plant, of which a good example was exhibited the other day by Mr. William Bull, at the Orleans House Show, is unique as regards character and aspect. It is a native of Western Tropical Africa. It is a plant of erect habit, the stems being closely beset with stalked spreading leaves, the petioles of which are of a greyish colour, and the blade yellowish-green streaked with dark green and silver-grey in alternate straight or furcate bands, the colours, as will be seen, being about equally distributed. The back of the unrolled leaves is a pale reddish-purple, and the stem, where visible at the upper joints, is of similar hue, the lower parts becoming green. It is one of the most striking of all Dracænas, and one which should find a place in all good collections of fine-foliaged plants.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

A Tomato Omelette.—Those who duly appreciate the Tomato will probably fancy they know all needful ways of cooking it; so did the writer, till he recently tasted a Tomato omelette, which is delicious. It is made by simply incorporating a few good Tomatoes (cut in not too small slices) with an ordinary omelette aux fines herbes.—V. T.

Irrigation.—The subject appointed for discussion at the usual monthly meeting of agriculturists held the other day in the Rue le Peletier, was the management and utilization of running waters. As indicative of the vast importance of this question, it is stated that if the natural waters of France were utilized in the same manner as those of Piedmont and Lombardy, 5,000,000 hectares of land could be irrigated in the place of the 100,000 now so treated, and pasture and forage would be increased fiftyfold.

Lily-white Seakale.—Early this spring this was awarded a certificate by the Royal Horticultural Society; but whether for novelty or for extra culture was not stated; if for the latter, a cultural commendation would have been more appropriate. The Committee should have known that this variety has been widely distributed by nurserymen along with the common Seakale. I have had it myself from two establishments, and in looking over the gardens at Newton House the other day Mr. Keely pointed out a great quantity of it intermixed with the old garden sort. Whether this is an accidental cross or a sport, I am unable to say, but certainly it is an excellent sort, and ought to be well looked after.—W. CULVERWELL, *Thorpe Perrow*.

Long-rooted Geranium (*G. macrorhizon*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

THE most attractive hardy flowers now to be met with in bloom are Columbines, Poppies, and numerous Irises. The dwarf blue-flowered *I. stylosa* is flowering freely. Feather Hyacinths may be found in good condition. *Eschscholtzia californica* and its white-flowered variety are blooming abundantly, and cut blooms of them are now being brought in large quantities to our flower markets, where they are used in the commoner kinds of bouquets. Several of the Alliums are now at their best, notably *A. subhirsutum*, which bears large trusses of white blossoms, and which, but for its offensive smell, would doubtless be largely grown for market purposes. Among Columbines now in flower may be named *Aquilegia glandulosa*, *A. cœrulea*, and the scarlet *A. truncata*. Various Cyclobothras are also blooming freely, the most showy being *C. pulchella*, which bears abundance of drooping, golden-yellow blossoms, and *Tovaria racemosa* bears numbers of creamy-white, Spiræa-like flowers. The showy *Collinsia*

Small bulbous Iris
(*I. Xiphium*).

Leptosiphon androsaceus.

bicolor, growing in large patches, is very effective, as are also *Limnanthes Douglasi*. Geraniums, too, are just now very showy, especially the large, purplish-blue-flowered *G. eriostemon*. *Oxalis articulata maritima* is a pretty little plant when grown in a moist soil; its flowers are of a deep magenta colour, and when produced in masses are very effective. Various kinds of Lupines are now amongst the most showy of border plants, and Larkspurs will soon be laden with blossoms. *Lithospermum prostratum* is now getting remarkably showy, its bright blue, star-like blossoms being produced in great abundance; the lavender-flowered *Veronica caucasica* is also blooming freely; as are also *Asphodels* and *Foxgloves*, both of which are just now at their best—the place for both is of course the wild garden or shrubbery. In addition to these, various *Salvias* are also flowering freely, as are likewise *Centaureas* and *Polemoniums*, and the beautifully-drooping blossoms of *Onosma taurica* are very showy. S.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY, REGENT'S PARK.

JUNE 15.

THIS was a most attractive exhibition, and one that seemed to be fully appreciated, for throughout the afternoon and evening both the tents and the gardens were thronged with visitors. The show itself was rendered more interesting than usual by the addition of a long stage of fruit, of which none has been shown before in these gardens this year. A group of new and rare plants, contributed by Messrs. James Veitch & Sons, contained numerous interesting examples of Fly-trap plants, exhibited under bell-glasses, which proved a source of great attraction. The grand bank of Orchids, too, was also greatly admired; it was without doubt the finest display of these lovely plants that has been seen for a long time. The examples of *Odontoglossum vexillarium*, shown by Mr. B. S. Williams, Holloway, and Mr. Denning, gardener to Lord Lodesborough, were marvels of good culture, as were also the neat groups of *O. vexillarium*, edged with *Adiantum gracillimum*, from Mr. Bull. In Sir Trevor Lawrence's collection, one specimen of *Masdevallia Harryana*, noticed elsewhere, was simply magnificent; it bore over thirty brilliant purple blossoms. Mr. Denning's group contained a well-flowered plant of the rare *Odontoglossum cirrhosum*. Among fruit the remarkable examples of *Muscats*, shown by Mr. Wilmot, Isleworth, were the admiration of Grape growers.

Certificates.—These were awarded in large numbers, but as they were not attached to the plants to which they were given until late in the day, we are unable to do much more than mention the names. Foremost on the list stand *Rhododendron Duchess of Edinburgh* (Veitch), a variety with long, tubular, crimson blossoms; *R. Maiden's Blush* (Veitch), a free-habited kind with white, rosy-tinted blossoms; *Acalypha Macfeeana* (Veitch), a sort with large bronze leaves blotched with fiery-orange-erimson; *Anthericum Veitchi* (Veitch); *Azalea indica imbricata* (Veitch), a double white and pink Balsam-flowered kind well worth attention; *Liparis elegantissima* (Veitch), *Croton Bismarcki* (Ball), a handsome form from the South Sea Islands. *Aquilegas*—Hybrids of *cœrulea*, *californica*, and *pyrenaica* (Douglas); Show *Pelargoniums*—*MaeArthur*, *Clara*, and *Bertie* (Turner); also *Zonales*—*Tom Bowling*, *Silvio*, and *Leveson-Gower* (Burley); of the silver-edged type were *Boadicea*, *Mrs. Hanbury*, *Mrs. J. Quennell*, and *Charming* (Burley); *Pelargoniums* *Prince of Wales*, *Prince Teck*, *Beauty of Oxtou*, and *Queen Victoria* (Bull); *Pelargonium Dr. Masters* (Williams), a free-habited kind with dark maroon semi-double flowers, a capital market plant; *Pelargoniums* *New Life* and *Purple King* (Cannell); *Senecio fl.-pl.* (Cannell), a dwarf-growing plant with double, whitish, button-like blossoms. *Mimulus* (E. G. Henderson), for excellence of strain. In addition to these the following also received certificates, namely, *Tropæolum Norwood Gipsy*, *Pelargonium Empress of India*, *Aralia ornata*, *Croton splendidum*, *Cyathea Dregei*, *Lomaria Dalgairnea*, *Cycas media latissima*, *Begonia Gloire de Nancy*, *Odontoglossum vexillarium roseum*, *Gymnogramma Novelleri*, *Pteris ensiformis variegata*, *Anthurium Warvequianum Veitchi*, *Dicksonia Besteriana*, *Coleus pictus*, *Aurancaria excelsa alba-spica*, *Zamia Roezli*, *Dieffenbachia Chelsoni*, *Croton Regina* and *C. hybridum*, *Petunia Madame Hengest*, Show *Pelargoniums* *Venus*, *Forget-me-not*, *Captivation*, and *Silvio*, Fancy *Pelargoniums* *Mrs. Pope*, *Henry King*, *Enterprise*, *Despot*, *Artist*, *Crusader*, *Goliath*, *Martyr*, *Medora*, *Evelyn*, and *Covenant*.

New and Rare Plants.—Of these, excellent groups were shown by Messrs. Veitch & Sons, Mr. William Bull, and Mr. B. S. Williams. Messrs. Veitch & Sons had an *Anthurium Veitchi* furnished with shining green and bronze leaves nearly 3 ft. in length; also *Croton Disraelii* in excellent condition, its bright orange foliage associating well with that of Ferns, *Aralias*, and Palms; the bright yellow *Oncidium concolor*; the crimson and bronze *Acalypha Macfeeana*; *Masdevallias* of various kinds; and other attractive plants. The same firm also showed the beautiful, pure white, wax-like *Lapageria alba*, *Rhododendron Taylori*, *R. Maiden's Blush*, and the bright crimson tubular-flowered *R. Duchess of Edinburgh*. In Mr. Bull's group we noticed finely coloured plants of *Croton Disraelii*, *C. Mortii*, *Dracæna Goldiana*, and some attractive *Pelargoniums*, named *Beauty of Oxtou*, *Princess of Wales*, and *Queen Victoria*. In this collection we also noticed a well-grown plant of *Paulinia thalictrofolia*, *Croton triumphans*, and a beautiful rose-coloured variety of *Odontoglossum vexillarium*: This group which was backed up with Tree Ferns, *Cycads*, and Palms was very effective. Mr. B. S. Williams had fine coloured plants of *Dracæna Baptistii* and *D. amabilis*, and examples of new Palms, and *Aralias*, the whole being relieved by brightly flowered plants of *Azaleas*, *Ixoras*, and *Scarlet-spathed Anthuriums*. Messrs. John Laing & Co. had a group in which were *Dieffenbachia Bausei*, some choice *Caladiums*, and other plants. A group of new and rare plants also came from Messrs. Rollisson & Sons, Tooting. Mr. Wills contributed baskets of his new seedling *Dracænas*, each containing three plants, and thus shown they were very effective.

Stove and Greenhouse Plants.—Collections of these were numerous, and contained many well-flowered specimens. Messrs. Jackson & Son, Kingston, staged capital plants of *Erica Cavendishi*, *Statice profusa*, and *Aphelexis macrantha purpurea*. Mr. Williams exhibited, amongst others, *Allamanda grandiflora* and *Ixora Prince of Orange*. Mr. Donald, gardener to J. G. Barelly, Esq., Knott's Green, Leyton, had good plants of *Hederoma tulipifera*, *Erica tricolor Wilsoni*, *Clerodendron Balfouri*, and a well-flowered example of *Ixora Fraseri*. Mr. Wheeler, gardener to Sir F. Goldsmid, had neatly-grown plants of *Heaths*, *Azaleas*, *Everlastings*, and *Pimeleas*; and Mr. Child, gardener to Mrs. Torr, Grand Hall, had good examples of *Erica depressa*, *Phenocoma prolifera* Barnesi, a profusely-bloomed specimen of *Polygala Dalmaisiana*, and a *Stephanotis* well studded with fresh white blossoms. Mr. Legg, gardener to J. S. Ralli, Esq., had well-flowered plants of *Clerodendron Balfouri*, *Allamanda grandiflora*, and *Statice profusa*; and Mr. Peed, Roupell Park Nurseries, Norwood, had excellent examples of *Bougainvilleas*, and a remarkably well-grown plant of *Erica Victoria grandiflora* thickly studded with bright rosy-pink blossoms. A well-flowered collection of *Heaths* came from Messrs. Jackson & Sons; and Mr. Legg also exhibited neat little plants of *Erica obbata*, *E. Candolleana*, and *E. Paxtoni*. A capital collection of *Dracænas* came from Mr. W. Bull; amongst them were examples of the spotted-leaved *D. Goldiana* and the narrow-leaved *D. triumphans*. Mr. Legg also showed a good collection of *Cordylines*, *Dracænas*, and other fine-leaved plants. Mr. C. Rann, gardener to J. Warren, Esq., had fine examples of *Crotos*, *Palms*, and *Dasyliorions*. Mr. Child had likewise well-coloured plants of *Crotos*, *Anthuriums*, and *Pandanads*. Mr. Donald furnished the graceful *Croton angustifolium*, *Cocos Weddelliana*, and a very large healthy specimen of *Pandanus elegantissimus*. Mr. Williams showed six gigantic specimens of *Palms*, *Pandanads*, and *Crotos*, also Ferns, amongst which were fine examples of *Gleichenias*, and the Bird's-nest Fern (*Asplenium Nidus*). Ferns also came from Mr. Rann, Mr. Ley, and Mr. Donald, who had a fine specimen of *Davillia Mooreana*, *Adiantum cardiochloenium*, and *Dicksonia antarctica*. Mr. Child had a well-grown plant of *Gleichenia Mendelli*.

Show and Fancy Pelargoniums.—These formed one of the principal features of the Show, there being upwards of a hundred specimens of them staged. The best half-dozen Fancies came from Mr. G. King, gardener to R. Few, Esq., who had *Roi des Fantaisies*, *Fanny Gair*, and others in excellent condition. Mr. James, Isleworth, had good plants of *Princess Teck*, *East Lynn*, and *Mirabile*. In the nurserymen's class, Mr. Turner showed finely-flowered examples of *Marionette*, *Excelsior*, and a light pink-shaded variety named *Nelly Fordham*. Of show varieties, Mr. Turner exhibited well-grown plants of *Highland Lassie*, *Claribel*, *Pompey*, and *Ruth*, fresh and profusely flowered. Mr. G. King exhibited well-flowered plants of *Hermit*, *Beauty of Kingston*, and *Exhibitor*; and in Messrs. Dobson's group were finely-blossomed plants of *Luna*, *Loveliness*, and a maroon-spotted kind, named *Favourite*, which was greatly admired. The same exhibitors also had good plants of fancy kinds not being so stiffly trained, as is too commonly the case. Mr. James had excellent plants of *Prince Leopold*, *Prince of Denmark*, *Mary Hoyle*, and *Snowflake*. Mr. Burley, Brentwood, showed a collection of Mr. Postans' Zonal and Variegated-leaved Pelargoniums amongst which we noted the brilliantly flowered kind named *Tom Bowling*; *Leveson Gower*, a beautiful salmon-coloured kind; and several good variegated varieties with white, salmon, or pink flowers. Mr. Turner exhibited baskets of new Pelargoniums, the first noticeable amongst which were *Silvio*, a bright crimson variety, with dark maroon upper petals; *Enterprise*, a large, well-formed rosy flower, with the upper petals deep velvety crimson, and white throat. Mr. Williams showed well-grown plants of his new Pelargonium *Dr. Masters*, which appears to be admirably adapted for decoration as well as for supplying cut blooms. Mr. Catlin, Finchley, showed half-a-dozen large Zonal Pelargoniums, amongst which *Coeur*, a brilliant scarlet variety, appeared to be an excellent kind for pot culture, as did also the pink-flowered *Mrs. Pearson* and the salmon-coloured *Mrs. Catlin*.

Orchids.—These were unusually attractive. The premier prize in the nurserymen's class was awarded to Mr. Williams, Holloway, in whose collection we noted a pan of *Cypripedium barbatum superbum*, with over fifty well-formed slippers; *C. niveum*, with nearly forty flowers; *Orchis foliosa*, with twenty spikes of purplish-lilac blossoms; and a magnificent plant of *Odontoglossum vexillarium*, bearing forty fully-expanded large and delicately-tinted blooms. Mr. Morse, Epsom, also had a good collection. The first prize in the amateurs' class was awarded to Mr. Denning, gardener to Lord Lonsborough, who had, amongst others, a *Laelia purpurata*, bearing some twenty large pure white-petalled and rich purple-lipped flowers; and *Odontoglossum vexillarium*, with nine gracefully-drooping spikes, each furnished with from eight to twelve flowers; *Dendrobium Bensoniae*, bearing twenty thickly-flowered pseudo-bulbs; and a good plant of the rare *Odontoglossum cirrhosum*, furnished with three long, pendent spikes, studded with beautifully spotted blossoms. Sir Trevor Lawrence showed, besides the *Masdevallias* already referred to, a remarkably fine plant of *Odontoglossum Phalenopsis*, over 2½ ft. in diameter, bearing scores of large, butterfly-like, white and pink-coloured blossoms. The same collection also contained examples of *Cattleya Warneri* in very fine condition, one plant bearing thirteen remarkably large blossoms. Mr. Hill, The Poles, Ware, showed a fine plant of the rarely-seen *Cologyne Lowii*, bearing six long flower-spikes hanging gracefully over the edges of the pots. Mr. Rutland, gardener to the Duke of Richmond, showed a specimen of *Brassia verrucosa*, and a plant of *Cattleya Mossiae magnifica* bearing fifteen large, finely-coloured blossoms. A miscellaneous group of Orchids came from Mr. Ollerhead, gardener to Sir H. Peck; amongst them were well-flowered plants of *Odontoglossum Alexandræ*, *Cypripedium barbatum*, *Cattleya Mossiae*, *Aerides affine roseum*, *Dendrobium giganteum*, and *D. Dalhousianum*; these were tastefully backed up by *Palmis*, *Ferns*, and other fine-foliaged plants. Roses in pots were furnished by Messrs. Paul & Sons, Cheshunt; amongst them were good examples of *Souvenir d'Elise*, *Celine Forestier*, *Juno*, *Madame Margottin*, *Laelia*, and other good sorts, all of which bore abundance of fresh and well-coloured blossoms.

Cut Flowers.—The most attractive of these were some boxes of *Roses* shown by Mr. Chard, Clarendon Park, Salisbury, amongst which were good blooms of *Souvenir d'un Ami*, *Maréchal Niel*, *Celine Forestier*, and *Lamarque*. Mr. W. Bone, Havering Park, Romford, had good trusses of *Maréchal Niel*, as had likewise Mr. James Bolton, Combe Bank, Sevenoaks. Mr. Soder also showed cut *Roses*. Mr. Douglas exhibited flowers of stove and greenhouse plants in good condition, as did also Mr. Bones, Mr. Morse, and Mr. Bolton. Blooms of *Pyrethrums* came from Mr. Roberts, Peterborough House, Fulham, and a miscellaneous collection of hardy herbaceous flowers were furnished by Mr. Morse, Epsom, noticeable amongst which were good spikes of *Feather Hyacinths*, *Lilies*, *Iris*, and *Saxifrages*. Mr. Douglas had collections of hardy flowers, amongst which were good trusses of *Squills*, *Statice*, *Spiraea palmata*, and various *Columbines*. Mr. Wheeler had also good examples of hardy flowers. Messrs. E. G. Henderson were awarded a certificate for seedling *Mimulus*, the blooms of which are very large, and embrace nearly every shade of colour. The prizes offered for groups of wild flowers brought forward three competitors, the principal one being Mr. J. Green, The Poles, Ware, who had four large boxes filled with really handsome flowers, amongst which were large trusses of the white *Campion* (*Lychnis diurna*), *Periwinkle*, *Sweet Briers*, *Welsh Poppies*, *Forget-me-nots*, *Honeysuckles*, *Butterfly Orchis*, and large-flowered *Mimulus* gathered from the banks of the Lea.

Miscellaneous Plants.—Mr. Ware, Tottenham, showed plants of a handsome new *Pink*, called *Newmarket*, a kind which bears rosy-pink, well-formed double flowers, and one which is likely to be largely

grown for market purposes, owing to its adaptability for forcing. A new bedding *Viola*, named *Freedom*, came from the same exhibitor. It appears to be free-growing and floriferous, and the flowers are of a deep bluish-purple, with a dark centre. *Bouvardia Humboldtii corymbiflora*, a kind resembling *B. jasminiflora*, only that the flowers are three times as large, came from Messrs. E. G. Henderson & Sons, who also showed a new double *Petunia*, named *Madame Hengest*. Mr. Cannell showed specimens of his *Pelargonium New Life*, and small plants of *Senecio fl.-pl.*, a double white-flowered kind of a useful character. Messrs. Jackson & Sons contributed well-grown plants of the beautiful pyramidal *Saxifrage* (*S. nepalensis*), which attracted much attention. Messrs. Laing & Co., Forest Hill, sent a group of new *Begonias*, amongst which a kind called *B. delicata* had creamy-salmon-shaded blossoms, and associated with it were a fine orange-crimson-flowered kind, named *Messange de Louvre*, and a violet-purple-flowered *Triteleia*.

Fruit.—This was fairly represented, and the quality of all exhibited was exceedingly good for the season. Mr. Miles and Mr. Bones showed collections of fruit. The former exhibitor had splendid brown Turkey Figs, well-coloured bunches of *Black Hamburg* and *Forster's White Seedling Grapes*, *Violette Hâtive Peaches*, *Elruge Nectarines*, and *black Circassian Cherries*. Mr. Bones had *Muscats of Alexandria* and *Black Hamburg Grapes*, two *Melons*, and good *Violette Hâtive Peaches*. Mr. Miles, gardener to Lord Carington, Wycombe Abbey, showed an excellent example of *Baroness Rothschild Pine*; and Mr. Douglas had a good *Queen*; good examples also came from other exhibitors, but they were scarcely ripe. Mr. Alchurst, gardener to S. Copestake, Esq., Kentish Town, had two well-ripened *Queens*, which, considering they were grown so near London, deserved great praise. *Grapes* were exceedingly well shown; Mr. Grimmett, gardener to J. Wilmot, Esq., Isleworth, sent three excellent bunches of *Muscats of Alexandria*, which had very large berries, of a fine amber colour. The same exhibitor also staged a basket of *Muscats*, which were certainly the best we have seen anywhere this year, and in each case the first prize was awarded. Mr. Douglas had a basket of *Canon Hall Muscats* of a very meritorious character; the berries were remarkably large, and of a fair colour for the season. Mr. P. Edwards, gardener to Mrs. Trestrum, Fawley, Hants, sent very large and symmetrical-shaped bunches of *Muscats of Alexandria*, which were fine examples of good culture, the only fault being that they were not ripe. Mr. R. Sowerby, gardener to Earl Macclesfield, staged three excellent bunches of *Foster's Seedling*, the berries of which, though not over large, were well-ripened, and covered with a fine bloom. The best *black Grapes* came from Mr. W. Bones, and Mr. Douglas had good bunches of *Black Hamburg*, bearing large and well-ripened berries of excellent colour; Mr. Bolton sent three good bunches of *Black Prince*; and Mr. Grimmett had good examples of *Madresfield Court*. A basket of well-ripened *Black Hamburgs* also came from Mr. P. Kay, Finchley. Of *Peaches* there were six dishes shown, the best of which came from Mr. Sowerby, Shirburn Castle, Oxon, who showed *Alexandra Noblesse*; and Mr. Cornhill, gardener to J. S. Virtue, Esq., had finely-coloured fruits of *Royal George*. Eight dishes of *Nectarines* were shown, amongst which were some finely-ripened fruit of large size; the best came from Mr. G. Holliday, gardener to J. Norris, Esq., Bletchley, who furnished bright, well-coloured examples of *Violette Hâtive*; a dish of the same variety also came from Mr. Sowerby. Mr. Cornhill had well-ripened fruits of *Pitmaston Orange*, and Mr. Miles good examples of *Elruge Melons* were shown in good numbers; Mr. Mortimer, gardener to Major Storer, Reading, had a fine fruit of *scarlet-fleshed Duke of Edinburgh*, weighing 5 lb. 4 oz.; and Mr. Gilbert, Burghley, showed a prettily-netted kind weighing 4 lb. 13 oz.; Mr. Gilbert also showed excellent-flavoured fruits of *Victory of Bath* and *Excelsior*. Mr. Miles had good examples of *Read's Scarlet Flesh* and *Coe's Golden Gem*. Four dishes of *Cherries* came from Mr. Miles; they consisted of well-coloured fruits of the *Black Circassian* and *Elton*. Mr. Worthing, Chadwell, had good dishes of *Premier* and *La Grosse Sucrée Strawberry*. Mr. Woodbridge and Mr. Roberts showed well-ripened pods of *Vanilla*, and Mr. Douglas furnished some good *Tomatoes*.

A list of the prizes awarded on the occasion will be found in our advertising columns.

QUESTIONS AND ANSWERS.

Wash for Rose Trees.—Can any of your readers kindly give me the recipe for a good, safe wash to protect Rose trees from blight, insects, &c.? I shall also be much obliged to any one who would inform me whether the following decoction would prove injurious:—Chips of Quassia, ½ lb., soft soap, 1 lb., water, 1 gallon, boiled together for twenty minutes, then strained and applied when cold.—MARÉCHAL NIEL.

Fertilising *Dielytra spectabilis*.—Will some of your readers kindly tell me (1) whether *Dielytra spectabilis* ever seeds in this country; and (2) how its fertilization is effected? The structure of the blossom is very curious. I suppose insects are the fertilizers, but the only aperture by which they could get at a sweet secretion in the side of the flower near the stigma is not present in all the specimens which I have examined.—FRANKLIN T. RICARD, *Lyme Regis*.

Beans and Wireworm.—Finding my Dwarf French Beans and Scarlet Runners come up very badly, I rooted up a few with a stick and found that most of the Beans had what I believe is called wireworm in them. What is the best remedy against such destructive pests? Will soaking the seed for a few hours in paraffin be efficient, or would digging in soot be of any use?—C. D., *Uxbridge*. [You might try both remedies, and we shall be pleased to hear with what result. Slices of Potato or Lettuce stems buried an inch or so under the surface of the ground and examined daily form good traps, and some have found salt to be a good remedy for wireworm.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE ABELE OR WHITE POPLAR.

(POPULUS ALBA.)

ABELE is said to be derived from Abeel, the Dutch name of this Poplar, which is also said by some to take its name from the city of Arbela, in the plains of Nineveh, near which, on the banks of rivers, it was at one time plentiful. It is supposed that this is the same tree as that mentioned in the Bible as Abel-shittim or Shittim-wood. The name White Poplar, as may be naturally inferred, is applied to it on account of the white and woolly under-surface of the leaves; its bark, too, except when old, is white and very smooth. It is probably truly indigenous in eastern and southern England, readily propagating itself by means of seed and suckers. The wood is white, soft, light, and very tough; it is used in this neighbourhood for bent ware, and made into various kinds of hoops for tubs, pails, and ship's masts, &c.; the timber is sawn into boards and strips from three-eighths to five-eighths of an inch thick; it is then steeped and steamed to admit of its being bent with ease and without splitting. It is also made into corn shovels, bottoms of tubs, pails, corn, and other measures, and also used in cheap cabinet and turnery work. I ought, too, to add that it is used extensively for railway carriage break-blocks, on account, I suppose, of the non-combustible character of its wood, which will bear almost any amount of friction without igniting; and, moreover, it is very durable under friction. I know, as a fact, that it makes bad firewood; it is hardly possible to make a good blaze of it. As a timber tree it is classed amongst inferior kinds, but it is the best of all the Poplars; at least it is preferred to any other kind in this locality. It is worth from 1s. to 1s. 6d. per ft., but the timber must be sound, clean, and of large dimensions to realize that price; smaller-sized and ordinary quality trees sell at from 10d. per ft. to 1s. per ft. The Black Italian Poplar (*Populus monilifera*) is used for similar purposes as the Abele; it is, however, a coarser tree with a more branching habit, and, as a rule, it does not cut up so clean and free from small knots as the latter, neither is its wood so white; it is not in such request for bent ware as the Abele, and in consequence it is hardly worth so much per foot in the market; these Poplars are both extraordinarily fast growers in moist, heavy land. The Abele exhibits a highly ornamental aspect in the landscape, particularly in spring, when the foliage is unfolding its whiteness, presenting a striking and pleasing contrast when associated with darker-foliaged trees. It is also a most distinct and effective tree, owing to the whiteness and smoothness of its stem exhibiting a glittering appearance, particularly during sunshine, when its bark looks almost as bright as polished silver. In the Oak coppices on the clay lands on this estate it is plentiful; numbers of young plants of it crop up from self-sown seed usually after a cutting of underwood; it is considered as an intruder, but as it adds much beauty to the otherwise monotonous colour of the Oak woods, it is allowed to grow in limited numbers where it does not injure or interfere with the growth of the Oaks. Allusion was made in the last number of the "Journal of Forestry" to the remarkably large examples of this tree in Longleat Park. Since these remarks have appeared I have carefully measured twenty of the largest specimens, of which the average sizes are as follow:—Length of stem up to the crown, 60 ft.; girth at 5 ft. up, 12 ft. 3 in.; girth at 20 ft. up, 10 ft. 4 in.; girth half-way up, 9 ft. 10 in.; contents of each tree, including the bark, 362 ft.; contents of each tree, exclusive of the bark, 303 ft.; height, from 80 ft. to 125 ft. The largest tree, which is perfectly sound, girthed 14 ft. 4 in. at 5 ft. up the trunk, 11 ft. 7 in. at 20 ft. up, and 11 ft. 2 in. at 30 ft. up (or half-way), the stem being just 60 ft. up to the crown, and without a branch or break; it is 110 ft. high, and contains 467 ft. of timber with the bark, or 387 ft. under the bark. I have allowed nothing for the tops, some of which are large, and

contain a quantity of measurable timber, but to allow an average of 50 ft. for each top would be considerably below the actual measurement. These twenty magnificent trees are nearly all sound; some few are slightly damaged in their tops through rough winds and dead branches decaying, otherwise their stems are pictures of health and soundness. Twelve out of the twenty of their colossal butts measure from 60 ft. to 80 ft. up to the crown, with hardly a branch on their entire length. The soil in which they are growing is a strong hazel loam, the subsoil being Kimmeridge clay; they occupy a rising or hanging piece of ground called The Grove, nearly in the centre of the park.

GEORGE BERRY.

Longleat.

NEW AND GOOD AURICULAS.

As Auriculas continue to engage much attention, your readers may wish for a few more notes of new and beautiful varieties exhibited at the recent shows of the National Auricula Society. 'Trail's Prince of Greens is a very striking flower, deep green and most pure in the edge, a very black body colour, and a dense, smooth paste; the eye, however, is sadly pale and cold, but still, the worse feature is the sharply-pointed petal, which the old florists used very descriptively to term "cat-eared." Nevertheless, it is a bright and telling variety. Whether it was the effect of heat or not I cannot say, but the foot-stalks of the pips were much too long and weak to hold the truss together. Talisman is another deep green edge, with black body colour and a lemon eye; every quality was good, nay, first-rate, except that the flower was cupped; this, however, may have been the effect of the cold, sunless weather in March and April. Turner's Arabella pleased me well; it is a white edge with a maroon body colour, a combination not often found; it is exceedingly circular in outline, and has a glorious golden tinge; its weak point is the paste, which is not as smooth as could be desired. Fanny Crossland is a very lovely white edge with lively blue body colour, decidedly a step in the right direction. It did not strike me as being so good as Mr. Simonite's other grand seedling Frank Simonite. The flowers were young, and I fear that the body colour as it grows old will usurp more than its proper share of room. I once raised a seedling singularly like Fanny Crossland, but was obliged to discard it for this fault. Among the selfs Master Hole is worthy of mention as being admirably dark, almost black in colour; it would, indeed, be hard to find fault with it if it were not that the paste is very scallop-shaped. Peacemaker is a bright-looking grey edge, with a good black body colour; it is one of a class in which we have plenty of good examples; but still it deserved the first-class certificate of the National Auricula Society, which was awarded it. Strange to say the same plant was passed over by the Floral Committee of the Royal Horticultural Society on May 2, and a first-class certificate was given to Sarah, a self which, in my opinion, was not worth the pot in which it was growing. It had distinctly Alpine blood in it, having two shades of body colour, and hardly an apology for paste. The Royal Horticultural Society is not likely to enhance the value of its certificates for florist's flowers by making such a blunder as this, and I cannot help imagining that Mr. Turner must think more highly of his Peacemaker, which has the certificate of the National Auricula Society, though passed over by the Royal Horticultural Society; than of Sarah. I cannot omit mention of the new class of edged or laced Alpines, shown by Mr. R. Dean, of Ealing. They greatly pleased and surprised me. I am no lover of Alpines; but the class of which Mr. Dean is the fortunate originator has much of the quiet grace and elegance of the true-edged Auriculas, without any of that staring, self-asserting look, which I so much dislike in the true Alpines. Mr. Dean's plants have a tolerably broad and very clearly defined border or lace round every petal; and there is considerable variety in the body colour. If he only succeeds in filling the tubes up to the surface with the anthers, and in getting rid of a certain slight pentagonal ridge in the centre of the flower, I make no doubt whatever that a brilliant future is in store for this class of plants. I would gladly grow a collection of them, while I would not admit an Alpine.

Cloghran, Co. Dublin.

FREDERICK TYMONS.

PERENNIAL WALLFLOWERS.

I AM indebted to the Rev. Harpur Crewe for some interesting additions to the few well-known forms of this family of hardy plants hitherto grown here. With better fortune than has fallen to my lot, Mr. Harpur Crewe has succeeded in securing some hybrids by means of crosses with the common Wallflower and certain perennial varieties. I have often tried to secure fertile seed from one of the best garden varieties (*Cheiranthus Marshalli*) by using pollen of yellow Wallflowers, but invariably without success, and I have concluded that *C. Marshalli* at least is a barren variety. Mr. Harpur Crewe has secured seedlings from *C. longifolius*, *C. mutabilis*, *C. helveticus* (*Erysimum helveticum*), and others that are little known in cultivation. A hybrid of *C. mutabilis* has flowers of small size that open pale lilac and deepen to a rosy-magenta hue. This gives a colour unusual in hardy spring flowers, and therefore will prove an acceptable variety. A hybrid between *C. Cheiri* and *C. longifolius* has flowers of medium size, and in colour rosy-bronze, a novel hue; this appears to have a robust perennial habit. A similar hybrid has flowers of the same colour, but the habit appears to partake more largely of the biennial Wallflower. A hybrid named *C. Sermoneri*, the result of a cross between *C. Cheiri* and *Erysimum helveticum*, is a diminutive yellow Wallflower, evidently too small to be useful as a decorative plant, but, nevertheless, an interesting variety. A very pleasing kind having semi-double flowers of a bright yellow tint, originally found in a cottage garden, is included amongst flowers and foliage which I have received; the spikes of bloom are small, and in the centre of each flower is a small, hard body of petals which, on being examined, is found to be a continuation of the stalk or branch, a feature which often occurs in Double Stocks—notably in the White Giant Brompton. In this Wallflower when the outer petals are shed, the small, hard point remains at the extremity of the branch. Of course, this is unfertile, but the plant is perennial as far as habit is concerned.

Through Mr. Harpur Crewe have also come some kinds raised by Mr. Ellacombe under the name of *C. Bocconi*. One of these has narrow-petaled flowers, of a bright yellow tint, borne on compact spikes, and evidently perennial in habit; also a variety that has narrow-petaled flowers of a brownish-yellow colour; this seems closely to resemble the Wallflower found on old walls. Another variety from Mr. Ellacombe is named *C. scoparius*, a kind indigenous to the island of Teneriffe, and therefore it is not surprising to find that it is somewhat tender. To Colonel Trevor Clarke is due the merit of having raised a hybrid from *Cheiranthus alpinus* and *C. Cheiri*; this has flowers of a pale yellow-buff colour, the edges of the slightly-crumpled spikes being thin and the foliage small. Perhaps few of these kinds will possess interest with cultivators, except in the case of those who possess a strong liking for hardy plants otherwise than merely for their decorative value; none in this respect would appear to excel the rich orange *C. Marshalli* or the pale yellow *C. ochroleucus*, so common in gardens. *C. Marshalli* has the reputation of being the result of a cross between *C. ochroleucus* and an annual orange *Erysimum*; whether two such distinct species would produce fertilised seed seems a doubtful point, but it is evident that *C. Marshalli*, although thoroughly hardy, does not possess that strong perennial constitution found in *C. ochroleucus*. *C. Marshalli* does not make wood so freely, is less easily propagated, and is less frequently met with. *C. Delabaynus*, a variety that is not unknown in the trade, is evidently a hybrid from *C. ochroleucus*, but the flowers are of a dull purplish-buff colour, and by no means attractive.

All these perennial varieties prefer dry and slightly elevated positions during winter, but like a cool, moist soil in summer. Propagation necessarily is by means of cuttings, but it is often found that by top-dressing with fine soil the summer wood is induced to root freely, and then in autumn the production of a good stock is easily accomplished. Cuttings should be taken off just as the plants are passing out of flower, put in under a hand-light and treated as Pink pipings usually are until rooted. Any of the biennial or Wallflower varieties may be propagated freely from seed, but varieties which it is desirable to perpetuate as distinct forms should be propagated by cuttings. Some of the old double Wallflowers are

found here and there, but rarely in what are called modern gardens; the large yellow and the bronze-red are the most abundant, but the old double-black seems to be quite gone out of cultivation. I have not seen this for many years. Of the varieties of the single Wallflower enough has been written from time to time, but these will live and flourish when myriads of present favourites have passed into oblivion.

A. D.

Early Summer Flowers.—According to present arrangements, early summer the most enjoyable season of the year, finds our flower gardens in a state of transition between spring gardening and the more gorgeous display of the late summer months; both displays are effective in their respective seasons, and when not overdone are usually satisfactory, that is, if subjects suited to the seasons be chosen, but it is by no means uncommon to find many plants recommended in works on spring gardening as being thoroughly suited for an early spring display, which in even ordinary seasons have no chance of getting into full bloom, much more of being on the wane, before they must be rooted up. For this reason I have lately adopted the plan of using only early flowering bulbs and plants, such as *Alyssums*, *Aubrietias*, *Primroses*, *Wallflowers*, &c., that can be depended on to give at least two months' bloom, in flower beds that must be cleared by a certain time, and of filling up mixed borders with *Collinsias*, *Silenes*, and such plants as are only coming into full beauty when the others are cleared off. We have now (June 18) a showy border of *Delphinium formosum* and *Roses*, associated with these early summer flowers, and large masses of *White* and *Pheasant-eye Pinks*. From these we can cut any quantity of bloom for flower baskets. Large clumps of *Tritomas* and *White Lilies* are just now opening their blossoms; in fact, from the earliest *Snowdrop* until the frost cuts down the latest *Tritomas*, there is always something from which to cut. It is, in short, not the use but the abuse of summer flowers that banishes real gems from our gardens; but, be this as it may, the mixed border provides a refuge for many beautiful plants that do not fall under the title of either spring or summer bedders, and should form both an interesting and useful adjunct to every garden.—JAMES GROOM, *Henham*.

Rhododendrons in Ordinary Garden Soil.—The experience of Mr. Beecher is entirely consistent with my assertion that the *Rhododendron* will succeed best in good garden soil, which in Long Island is a light, rich, alluvial loam. The soil of Mr. Beecher's country place we understand to be heavy clay. The *Rhododendron* has a large number of small fibrous roots, which eagerly enter into open, friable soil, and which are repelled by a stiff, hard clay. To make the latter resemble the former, there must be a mixture with it of some light material. For this purpose peat is good, because it contains some vegetable matter. It is not surprising that plants taken from the friable soil of Long Island, or the peat beds of England, should languish in clay. *Rhododendrons* imported from England and sent out with balls of peat will not grow even in our Long Island soil until they have had time to send out roots into the good garden soil around them. The sum of the whole matter is that for a stiff clay soil any lightening material is good, but for a light, friable soil any lightening material is injurious. The sun will pierce and burn it, and will leave the plant to the rigours of a cold winter in a half-sick state, in which it may either languish or die. If, misled by the experience of cultivators in the cool, moist climate of England, any have been induced to make a peat-bed in a light, friable soil, their only remedy is mulching. Nothing else will save them from the inevitable result of their error. Our opinions are based upon an experience of thirty years, during which we have grown many acres of *Rhododendrons* without a particle of peat and in open sunshine. We have always considered the peat and shade fallacies a great bar to successful *Rhododendron* culture.—S. B. PARSONS, *Flushing*, in "Gardeners' Monthly."

Lilium Szovitzianum.—Five years ago I purchased a bulb of this noble Lily carefully taken up with its roots. The first year it had three blooms; the second, five; the third, eight; the fourth, fifteen; and this year it has fifteen again, all on one stem, as it has never sent up a second one, a peculiarity said to belong to it. It will be interesting to learn from any of your readers what is the greatest number of blooms this Lily has yet produced.—G. F., *Heckam*.

Flowering Echeverias.—Although when used for bedding purposes these are undesirable, yet some of the varieties of *E. secunda*, when in full bloom, are exceedingly ornamental, and the flowers are singularly graceful. The stout, hard-wooded character of the stems, and the firm substance of the flowers render them specially permanent when cut, whilst their drooping form places them in the front rank as regards material for table decoration. The variety most commonly grown is *E. secunda glauca*, but the best-flowering kind is *E. secunda major*, a variety which invariably produces from two to three racemes of flowers on each stalk, and thus gives as a rule double the quantity of bloom produced by any other sort.—A.

NOTES OF THE WEEK.

FREESIA LEICHTLINI.—This beautiful bulbous plant, from the Cape of Good Hope, is now flowering freely in Mr. Ware's nursery, Tottenham. Its habit resembles that of a dwarf-growing *Ixia*, and the flowers are produced freely in trusses on slender, branching, wiry stalks, from 12 in. to 18 in. in length. It is at present in pots, but when it becomes more plentiful it will be tried in the open ground, where, if planted in a warm, sandy, well-drained soil, and slightly protected during severe weather, it will doubtless succeed perfectly. It is, however, valuable as a pot plant for conservatory or room decoration; for, when laden with its white, waxy *Gloxinia*-like flowers, which have a slightly spotted yellow throat, and which are deliciously fragrant, few bulbous plants are more beautiful or deserve more attention.—C. W. S.

ORNITHOGALUM ARABICUM.—We have received from the New Plant and Bulb Company, Colchester, cut specimens of this beautiful *Ornithogalum*, a plant which has always been considered difficult to flower; the specimens before us, however, prove the contrary to be the case, at least, at Colchester. The flower-stalks sent, which are about 2 ft. in length, are each surmounted by a fine cluster of pure white-petalled blossoms, set off by a black, glossy, head-like centre, and golden-tipped anthers. On account of its very attractive character when in bloom, as well as the usefulness of its sweet-scented flowers in a cut state, it would be interesting as well as profitable to learn by what method of culture this *Ornithogalum* succeeds so well at Colchester.

CHERRIES AND PLUMS IN COVENT GARDEN.—Cherries are now arriving in enormous quantities from the south of France; some are packed in round half-bushel baskets, others in square ones made of white Willow. They look ripe and good, but they are inferior in flavour to English Cherries; they are sold by auction in lots consisting of three baskets, and fetch from 7s. to 8s. 6d. per lot. Plums, resembling in appearance Greengages, but larger and very inferior in quality to that kind, arrive in small wooden boxes, each of which contains about four dozen fruits. Though not uninviting in appearance, being covered with a rich white bloom, they are not good as yet; but in a few weeks we may expect their quality to be much improved.—S. C.

IXIAS AT TOTTENHAM.—These handsome plants are rarely grown in large quantities, owing to their supposed inability to withstand our English winters. It is not, however, severe frosts that affect them so much as cold, cutting, easterly winds in spring, when the plants have commenced to make young leaves and bloom-buds. In the Tottenham Nursery several long ranges of frames, from which the sashes have been long removed, are now full of *Ixias*, the flower-spikes of which may be counted by thousands, and all are thickly beset with brilliant blossoms of all shades of colour, from pale green to the deepest magenta and crimson, collectively forming one of the most gorgeous floral displays imaginable. If mixed varieties of these were planted in clumps by the sides of shrubbery or *Rhododendron* borders in warm, sunny positions, where a hand-light or some such protection could be given them, there is no reason why *Ixias* should not form one of the principal attractions in our gardens in June.—S.

WALL SHRUBS AT KEW.—No matter at what season of the year one visits Kew, there is always something interesting on the walls. On those surrounding the herbariums department may now be seen *Habrothamnus corymbosus*, laden with clusters of reddish-coloured blossoms; *Convolvulus Cneorum*, thickly studded with white and rosy flowers; and the beautiful though well-known *Ecremocarpus scaber*, finely in bloom. Associated with these are also *Berberis cristata*, well furnished with light pendent clusters of blossoms. The Tree Medick (*Medicago arborea*) is likewise very attractive, being covered with bright yellow, *Coronilla*-like flowers; the yellow blossoms of *Fremontia californica* are also very showy, as are likewise the flowers of *Cytisus ramentaceus*, and the well-known *Cytisus* of our greenhouses (*C. racemosus*). *Rosa sericea* is also laden with white flowers, having pale-coloured stamens and light brown anthers.—S.

GUARDING AGAINST THE PHYLLOXERA.—The vast importance to France of every thing connected with the ravages of the *Phylloxera* (or Grape Vine Louse) is attested by the fact that a large proportion of all the communications made to the Academy of Sciences in Paris are on that subject. A permanent Commission has been established by the Academy, to which all matters relating to the *Phylloxera* are referred. With regard to the protection of the non-infected region against invasion, this Committee has recently recommended the following propositions:—first, the prohibition of the transmission of Vine cuttings from any infested district; second, the prohibition of the introduction and planting of cuttings of infested Vines in an

uninfected region; third, when an uninfected region is found to be attacked, to dig up all the plants completely, and burn every portion of them, and then to thoroughly disinfect the ground; fourth, to extend this disinfection of the ground to all the cuttings to some distance outside of the suspected spot.

A DISTINCT CLEMATIS.—There is now in bloom in the Paris Garden of Plants a *Clematis* with bright orange-red flowers; these are small and close, reminding one at first of a *Cuphea*, but the habit is of course graceful and the colour bright.

HALIMODENDRON ARGENTEUM.—This is a most beautiful bush, now bearing numerous and delicate rose-lilac blossoms, the habit being open and light. It is one of the greatest favourites in my bank of choice shrubs, and it deserves to be widely known.—R.

THE CUT-LEAVED WALNUT.—M. Carrière informs us that he raises this form, figured in *THE GARDEN* of last week, from seed of the variety *heterophylla*. From this tree 60 per cent. of the seedlings belong to the cut-leaved Walnut.

MECONOPSIS ACULEATA.—This grand addition to Poppyworts is now in flower in the York nurseries. It has stems loaded from top to bottom with glorious deep blue blossoms shaded with violet, and a centre of rich yellow anthers.—R. P.

A NEW GYPSOPHILA.—Dr. Moore sends us from the Botanic Gardens, Glasnevin, a very distinct dwarf species of *Gypsophila*—*G. cerastioides*. It is from northern India, and was raised from seed sent last year to Glasnevin; it is quite unlike any of the same genus now in our gardens, dwarfier, and with larger flowers.

CHAMEROPS EXCELSA IN CORNWALL.—Our specimen of this hardy Palm (which has been planted about twenty years) is now in full bloom; it bears seven large trusses of a most beautiful golden colour. I should like to know if there be any better specimen of this Palm in the open air in this country. Ours has a stem 8 ft. in height, and the extreme height of the plant is 12 ft.—WILLIAM HOVELL, *Heliyan*.

NEW HELIOTROPE.—A finely-grown plant of a mauve-coloured *Heliotrope* has been sent to us by Messrs. Beckwith & Sons, of Tottenham, raised from seeds of the well-known *H. Florence* *Nightingale*. It has a dwarf and compact habit, and the flowers, which are produced in great profusion in large trusses, are agreeably scented. It will no doubt become a good market plant.

BORONIA ELATIOR.—This graceful, free-flowering, new *Boronia*, of which a coloured representation was given in *THE GARDEN* for September 23, 1876, is now finely in flower in Messrs. Veitch's nursery at Chelsea, where plants of it may be seen growing in 6-in. pots in the form of dwarf standards; their gracefully-drooping branches are thickly laden with bright rosy, bell-shaped blossoms, which have a charming effect.—S.

HARVEST AND SPRING.—The Grass Valley (Californian) "Union" gives an account of an Apple tree growing in the orchard of Dr. Harris there, as follows:—"A large Apple tree, standing near his dwelling, was left last autumn with the fruit ungathered—for the birds, the Doctor said. As we write, a large number of golden Apples adorn the tree, while the fragrant pink and white blossoms seem begging for room to start a new crop. The green foliage, now well advanced, crowns the whole—altogether a spectacle rarely seen elsewhere."

ADIANTUM LUNULATUM.—This very distinct and handsome East Indian stove Fern has a slender, pendulous habit of growth, and is peculiarly adapted for growing in baskets or on blocks. Its fronds, which are pinnate, have the pinnae alternate and lunulate; they are bright green in colour, and about 1 ft. in length; stipe and rachis black, changing towards the apex. This being a deciduous species, care must be taken that it does not get too dry during winter. It may now be seen in beautiful condition at Mr. B. S. Williams', Holloway.—S. B.

FRUIT PROSPECTS IN MASSACHUSETTS.—The temperature here is increasing—88° in the shade; still, on account of the ground being well soaked by the late rains, vegetation is making great progress, and owing to the very dry and ripening season of last year the bloom on trees and shrubs has been extraordinary. Of Apples we have no crop, but Pears, Quinces, Cherries, and berries of all kinds are very promising. Potato bugs are committing great destruction.—WM. FALCONER, *Botanic Gardens, Cambridge, Mass.*

FRUIT SHOW AT ALEXANDRA PARK.—An international fruit show is to be held here on September 13, 14, and 15, when prizes amounting to upwards of £350 will be offered for all kinds of fruits, vegetables, table decorations, and a few cut flowers. The schedule is now in course of preparation, and will shortly be ready, when it may be obtained on application to John A. M'Kenzie, 1 and 2, Great Winchester Street Buildings, London.

THE FRUIT GARDEN.

PROTECTING FRUIT TREE BLOSSOMS.

Many say "Of what use is protection if when the pinch comes we lose our fruit?" I must admit that in bleak, exposed districts nothing but a glass structure—the larger the better—will, in all seasons, secure a crop of the choicer kinds of fruits, such as are commonly grown on walls. In all places, therefore, where the cost can be borne, it is better to adopt this plan at first than spend money on partial or temporary expedients that are not trustworthy; half-measures are seldom or never satisfactory. It is well also to put in a row of hot-water pipes, especially in narrow houses. In good-sized, roomy structures it would seldom be necessary to use artificial heat, but its presence even there gives such a sense of security that it is always money well spent to have it at hand in case of necessity. At all times it should, however, be used with caution, and never resorted to unless it is necessary to keep the temperature from falling more than a degree or two below the freezing point. During our occasional damp, sunless autumns the wood often lacks the necessary maturation for the development of strong and perfect blossoms, and there is in consequence a scarcity of fruit the following season even if spring frosts do not prevail to an injurious extent, but a glass roof would obviate all this; in fact, I am not sure if in the case of some stone fruits the perfect ripening of the wood is not of more importance even than protection in spring, for without well-ripened wood the flowers will be imperfect, and fail to set, even if the spring be favourable; and if it be unfavourable, protection scarcely ever secures a good crop. No doubt early disbudding, and timely and persistent attention to the destruction of insects have an important bearing upon the early and healthy development of the young wood; but even where all necessary attention is given in a difficult autumn for wood ripening, only those trees in the best and warmest aspects can be said to have a fair chance of securing the requisite amount of vigour in the embryo buds to make sure of a good set of fruit.

In many old-fashioned gardens the Peach walls are heated by means of flues, which are often of great use in ripening the wood in autumn, as well as in warding off sharp frosts in spring; but they require to be in careful hands, and the merest rubbish only burnt, or the walls near the fireplaces would be too hot. In my young days I had the management of the fires on a long stretch of flued Peach wall, and the fuel was nothing but the cinders from the other fires mixed with rubbish. The cost was a mere trifle, and the extra expense in constructing the flues (if any was incurred) would be counterbalanced in the saving of bricks, an item of considerable importance now that building materials have advanced so much in price. Good, however, as these may be, I should, as I have already stated, prefer good, roomy, substantial houses for fruit-growing, and believe that where a certain regular supply is required, this system will in the long run be found the best and cheapest; but the number of places where glass structures can be devoted extensively to fruit-growing will, I fear, always be limited. Many owners of property will doubtless continue to surround their kitchen and fruit gardens with walls; it is an old custom, and gives a sense of security and dignity to a place; if, however, they must have walls, in all new places, one or more of them should be traversed by flues for the choicest kinds of fruit; and if during a cold, wet autumn a very little artificial heat could be circulated through the interior of the wall, and radiated from its surface, there would be a greater chance of the wood ripening than would otherwise be the case. Last season was a difficult one for wood ripening, and many of the blossoms were on bad aspects weak and imperfect, a circumstance which has contributed in no small degree to failure this year. In confirmation of this I may say that our strong, healthy Peach trees on south walls—where the wood was made early and had a chance of ripening—were carrying a fair crop; in fact, in some instances I have had to thin, and there are still more to take off. Apricots have not fared so well, but even with those trees on a south wall that had the best chance of ripening their wood are furnished with a few fruit, whilst on an east wall, where the covering was thicker, the failure is nearly complete.

In the course of the last twenty-five years I have tried several kinds of covering in different counties, and under different conditions, and I have always found that trees somewhat thinly covered with feathery sprays of Yew with one, or in bleak situations, two thicknesses of fishing-net over them compared favourably with those protected by any other coverings short of a glass roof. In exposed situations there is always a difficulty in the case of frigi domo, or any other thick woven covering in securing them against wind, and as soon as they get a little the worse for wear, if a stormy day or night comes, they tear the nets into shreds and half ruin the trees. Trees under Yew branches and fishing-nets, on the contrary, are always

snug; and as the days lengthen, and they require more air and less protection, the leaves on the Yew branches gradually wither and fall; and if they do not fall fast enough, it is an easy matter to remove the nets and thin out the branches, operations which give an opportunity for looking out for insects at the same time, and dusting a little Tobacco-powder amongst them if any be visible. A flued wall carefully managed, with a thin covering of Yew branches and fishing-nets would be, I think, practically safe in most districts; but after all we must look more to well-ripened wood in autumn for a crop, without neglecting spring protection, but of the two I take the former to be the most important.

E. HOBDAY.

COVERING EARLY VINE BORDERS.

Discussions upon the different methods employed in the cultivation of particular plants, whether grown for their fruit or as decorative subjects, are no doubt calculated to benefit horticulture by elucidating the best and most suitable treatment necessary to meet the requirements of the plant or plants under consideration; but to effect this, it is essential that both parties engaged in the discussion be actuated by a sincere desire to establish and make clear the soundest practice, and not influenced by a disposition to carry their arguments right or wrong. Unfortunately the latter too often appears to be the governing motive, and the present discussion between Mr. Simpson and myself is not an exception. The real question in the first instance, as I have before stated, was a very simple one—the necessity or otherwise of using fermenting material on early Vine borders. I have brought forward sufficient evidence to satisfy any unprejudiced person that as good early Grapes are grown without, as with the use of, fermenting materials; Mr. Simpson has not brought forward a particle of evidence to controvert what I have advanced, or to substantiate his own views. Instead of arguing the case on its own merits, he has from the first tried to rest the issue upon the worn-out, exploded theory, that because bottom-heat is requisite for some plants, it is necessary for all that need considerable artificial warmth in which to grow. Mr. Simpson has, without cause, charged me with a disposition to evade the real question; your readers, I think, will have little difficulty in seeing who has evaded it. At p. 474, Mr. Simpson still adheres to his tactics in referring to the cultivation of plants that are as different from the Vine in their nature and requirements as they can well be; and he unfairly represents (see p. 471) what I had written upon growing Cucumbers in frames on ordinary beds of fermenting material. He says that "I tacitly recommend a bottom-heat for Cucumbers of 85° or 90°," and tells us that this is much higher than is necessary or desirable for them, which every one who knows anything about Cucumber growing is aware of, if kept up for a continuance. Mr. Simpson does me the injustice of not adding that I merely stated that Cucumber plants would bear turning out in the beds when the heat had subsided to this temperature; as in a bed of fermenting material the temperature would quickly fall much lower, as Mr. Simpson doubtless must know. But what, may I ask, has this to do with the question under consideration? If Mr. Simpson would confine himself to the simple question involved, and give us some practical proof that would bear out his views, we might arrive at something definite. I may remind him that mere assertion, having nothing more solid to rest upon than analogy and threadbare theories, is valueless.

T. BAINES.

New Early Peaches.—Mr. C. Downing says, in the "Gardeners' Monthly," that he worked the Alexander, Honeywell, and Amstden's June Peaches on the same tree, and they all ripened together. The leaves were different, but the fruit looked alike, and could not be distinguished when placed together.

Cox's Orange Pippin.—The merits of this Apple are well known, and indeed they are so conspicuous that in common with other good fruits it is always speaking for itself, and hence it is everywhere largely propagated and extensively planted, and is on the way to take the lead in the Apple garden, and prove to all that our declaration in its favour is warranted by the facts. It is one of the best paying Apples in Kent, and it is one of the few that may be trusted for a crop in those damp alluvial valleys or "bottoms" where spring frosts make the most havoc, and fruit-growing is a precarious business. Our observations of this variety, under many different circumstances, have been enlarged in a striking manner within the past few weeks. In our fruitful land in the valley of the Lea, the Hawthornden is a prodigious cropper, and about twenty better varieties compete with it for popularity, not the least important amongst them being Shepherd's Fame, Lemon Pippin, Ecklinville, Cellini, Old Nonpareil, Keswick Codlin, and Blenheim Orange. This year Cox's Orange beats them all, for the trees are smothered with fruit; while on all other sorts the crops are comparatively thin, more or less. It was precisely the same in the compartment occupied with Apple stocks in the Royal Horticultural Society's Chiswick garden, last year. The little trial trees of Cox's Orange were then well covered with fruit, while other varieties were barren or nearly so. The uninitiated reader may be disposed to ask what is the quality of the fruit we laud in this way? Well, the question is pertinent. The answer may be summed up in a few words. Cox's Orange is a better Apple than the Ribston Pippin, being as handsome, as well flavoured, and with more tender flesh.—"Gardeners' Magazine."

THE PALMS AND THEIR USES—THE WINE PALM.

With the exception of the Grasses, among which the various cereal plants find their places, there is probably no Order of plants more important than that of the Palms. For the most part natives of tropical countries, where they form the most striking feature of vegetation, their importance is hardly realized among us; yet a very little reflection will convince us that to those whose lot is cast in these regions, the Palms are of pre-eminent and almost infinite value. Of the Cocoa-nut

Palm, for example, it has been said that it contains in itself everything necessary to human existence: food, drink, furniture, clothing, oil, medicine—all these are furnished to the Cingalese by this beneficent tree. "The princes of the vegetable world," as Linnaeus called them, "the loftiest and stateliest of vegetable forms," to use the words of Humboldt:—whether we consider Palms from an æsthetic or a utilitarian point of view, we cannot fail to be struck with their varied forms and properties; and they are familiar to us from our earliest youth, being mentioned in the sacred writings from the encamping of the Israelites under the Palm trees of Elin down to the time when they were strewn in the triumphal path of the Founder of the New Dispensation; and yet again in the Apocalyptic Vision. Palm oil, Betel, Sago, sugar, wax, Dates, ropes, brushes, and very many more equally useful

articles are furnished us by members of the Palm family, showing that the 600 or 700 species which it contains are not dependent upon their beauty for their claims to our notice; while in its fermented form of arrack, the juice of various Palms is probably more widely used than either the wine or brandy which is produced from the Vine, or the whiskey or beer which is derived from Barley. The three rooms in the Kew Museum which are devoted to the economic products of the Palm tribe, are sufficient evidence of their variety and importance.

The species represented in our figure is *Caryota urens*, popularly known as the Wine Palm, which name, however, is also given to *Cocos butyracea*. The genus of which it is a member is a small one, containing only nine species—which number might probably be yet further reduced—all of them natives of India and the adjacent islands. They are lofty trees, having bipinnate leaves, which are easily recognised by the shape of the leaflets; these, instead of being long, narrow, and tapering, as in most Palms, are wedge-shaped, tapering to

the base, and broad at the upper extremity, where they are curiously and irregularly toothed or jagged. The male and female flowers are borne either upon one spike or occasionally upon separate ones, and the roundish, fleshy fruits are of a purplish hue, each containing one or two seeds. The fruits of *C. urens* are very sharp and acid; so much so, indeed, that it is stated they will produce a strong burning sensation if applied to the skin, and from this property the species has acquired its specific name. Although certainly of less economic importance than the Cocoa-nut and some other Palms, this *Caryota* is a very useful tree. Beginning with the trunk, a small quantity of very hard wood is yielded by its outer portion, of which the Cingalese make pestles for beating their Rice. The inner portion or pith of the trunk is much more important; it is made by the natives into bread, or boiled by them

The Wine Palm (*Caryota urens*).

into thick gruel, in either of which conditions it is highly nutritious; it has the same properties as Sago, of which it may be considered a kind. From the leaf-stalks a very strong, tough fibre is obtained, called Kittul or Kettule fibre; from this many articles are made, such as ropes, brooms, and baskets; while a woolly material, which is scraped off the base of these stalks, is sometimes used for caulking boats; the leaf-stalks themselves are employed as fishing-rods, for which they are very suitable, being light, tapering, and elastic.

The most important part of the tree, however, is the spike

of flowers, from which a large quantity of the juice is obtained; this juice is known as toddy, or Palm wine, and it is stated that as much as 100 pints will be yielded by a good tree in the course of twenty-four hours. When boiled, this juice yields very good Palm sugar, or jaggery, as it is called: about 8 gallons of the juice, boiled over a slow fire will yield 4 gallons of thick syrup. To this syrup small pieces of the bark of *Shorea robusta* (the Saul Tree) are added, and when boiled again the jaggery is produced. The manufacture of this sugar is undertaken by a particular caste of natives, and from this Caryota and two other Palms (*Cocos nucifera* and *Borassus flabelliformis*) all the sugar used in Ceylon is obtained. Some of the finest quality, made by the head men, forms an excellent substitute for Chinese sugar-candy. The cakes of jaggery, which are about as large as an ordinary bun, are wrapped separately in Plantain or Banana leaves, and are hung up until required for the market or for other purposes. The tree is sometimes called the Jaggery Palm, from the product which it yields.

Although not so common in cultivation as some other Palms, the Caryota is sometimes met with; there is an example of it under the dome of the Palm stove at Kew. B. J.

A Primrose Field.—Is it possible to write or say anything new regarding the pale Primrose? We are all familiar enough with it in the woods and on the hedge banks, but few, I question, have seen it in such grand display as it is to be found in a locality on the banks of the North Tyne, near the little village of Charlton. A long narrow field—about three acres, bordered on the river side with Hockberry trees and on the opposite side with a very tall hedge—is covered with immense patches of this Primrose, the whole making a gorgeous and a joyous sight, many of the individual plants being of great size. The field is so overrun by rabbits that no stock of any kind are ever put into it, and as the rabbits do not meddle with the Primroses, they flourish and spread at their own sweet will. Two plants bear very double flowers, and two single white specimens have been found amongst them this spring. The season being late here, the grand display is only just now going off, and those who have seen this Primrose field will not soon forget the sight.—G. F., *Bellingham*.

Spring Bedding Plants.—Owing to the lateness of the season these are late in blooming this year, and where spring gardening is carried out summer bedding must be proportionately late. Spring-blooming plants have much to recommend them—their hues are, for the most part, soft and chaste; their whites are pure, their blues pleasing, and their reds soft and subdued; they possess no fiery colours nor strong contrasts; and they flower at a time when there is no scorching sun which renders masses of colour in summer so intense as to make them painful to the vision. Even a bed of Tulips seen in full bloom in April is not offensive, inasmuch as the light is not yet too glaring and the surroundings are fresh and green. Hardiness, too, is a great recommendation to spring flowers. Violas and Pansies, Primroses and Polyanthus, Arabis and Alyssums, Anbrietias, Forget-me-Nots, Silences, Daisies, Wallflowers, Stocks, and many others, all hardy, make up a list that will satisfy the most exacting for variety in material and colour. The beds should be filled in November in whatever way may best suit the taste of the operator, and then there will be an abundance of floral beauty from early in March to the end of May; the filling up for the summer will be done early in June with well-prepared plants, and the beds are thus in use and in beauty almost all the year round.—A. D.

Plants Sleeping.—Several members of the Parisian Biological Society have recently been engaged in a series of experiments which seem to prove that everything endowed with life, whether animal, plant, or ferment, is susceptible of being brought under the influence of anaesthetics—in other words, may be sent to sleep. It has been proved that the influence of anaesthetics extends to all the animal tissues, and last of all to the central nervous system. Hence, it was argued, plants having tissues must be also subject to the influence of ether, &c. Experiments have proved this to be the case. Germination is arrested by anaesthetics. The Watercress, for example, germinates within thirty hours. Ether arrests germination in this plant, but does not destroy that faculty. It merely sends the plant to sleep, for germination recommences as soon as the use of ether is suspended. This capability of being sent to sleep is not confined to plants—it extends to ferments. Thus the ferment of beer, when submitted for twenty-four hours to the influence of ether, becomes perfectly dormant, but recovers activity as soon as anaesthetic action is suspended.

THE GARDEN IN THE HOUSE.

FLORAL DECORATIONS.

ROSES.

VERY effective table decorations can be formed by arrangements composed of Rose blooms only, with the addition of Ferns and Grasses in the way of foliage. Roses are always obtainable during the summer months, as all gardens, however small, are certain to contain a few Rose trees. Looking at a Rose bloom one would suppose it to be a flower very easily arranged, but this is not the case, for being of a large size (I am speaking of a full-blown Rose) when many blooms are grouped together the vase is likely to have a heavy appearance, and for this reason overcrowding must of all things be avoided in vases composed of Roses. As to the stands and vases in which they are arranged I like those made of clear glass best; but there is no use in saying one of this form or that should be employed, as that which I might describe might be one which some of your readers did not possess, though they might have many others which would be quite as effective. I shall therefore leave the selection to their own good taste. Some arrange their flowers in Moss, some in wet sand, and others in water for flat tazzas or March vases. I like sand better than Moss, as the flowers remain more upright and in whatever position they may have been placed, but for glass baskets, troughs, &c., water is best, as if seen the sand looks unsightly. Narrow glass troughs are very fashionable now on the dinner table as receptacles for flowers; but I do not admire them, as they have a set, formal look about them, a thing which I always try to avoid. Those who do not agree with me on this point, and who admire these troughs, will find small Rose buds better for their decoration than more expanded blooms—those, for instance, of the Moss or old Cabbage varieties. For placing in specimen glasses I like a single, half-expanded flower associated with its own foliage, as when this has been done, the leaves can be twisted and placed wherever required as easily as one would an artificial spray. The manner in which a Rose leaf is wired is as follows:—If you look at the back of a leaf it represents a stem with a few leaflets on each side, and one at the end or top; down the centre of each of these leaflets is a thick rib with slighter ones branching from it. Take a piece of thin wire, press it through the top leaf under one of the slight ribs, bring it up on the opposite side of the rib, as if you were sewing, and pass your stitches under the ribs, keeping the long stitches on the wrong side of the leaf; cut the top of the wire off, so as not to allow it to project above the leaf, and twist the other part round and down the stem, but care must be taken to avoid the wire being visible. As mounting in the above way takes some little time, I would advise only those about to be placed in specimen glasses to be done in that way. To arrange Roses in a March or three-tier stand, the largest or full-blown should be in the lower tazza, half-blown ones in the next, and only buds, &c., on the top tazza or trumpet. In placing the blooms they should just touch each other; in fact, their foliage, &c., should just cover the sand or whatever else they may be arranged in. Field Grasses look very well interspersed among Roses and Ferns. In arranging a stand of Roses of more than one tier, their colours should be shaded off as well as their sizes graduated. For a small-sized dinner-table decoration suited for everyday use, a vase in the centre and four specimen glasses grouped round it will be found very pretty and not too heavy for a small table. Should this, however, not be deemed large enough, a few glass baskets filled with Roses might be added—say four—in addition to the specimen glasses.

ANNIE HASSARD.

Woodwardia radicans cristata.—This is an interesting variety of the *W. radicans*, and makes, when grown in a basket, a graceful object; the fronds, which are drooping, average from 18 in. to 21 in. long, each pinna being crested; at the apex of the frond there is generally a tassel, often attaining large dimensions. This will be found useful both as a decorative and exhibition plant; and it will thrive either in the conservatory or temperate house.

Poisonous Anthurium Seeds.—The poisoning of rats with the seed of *Anthurium Scherzerianum* is reported by Mr. T. M. Shuttleworth, of Preston, in the "Journal of Horticulture." It appears that some newly-gathered seed was placed in one of Mr. Shuttleworth's Orchid-houses to dry, and a portion eaten by the rats. Its poisonous properties were made evident by the discovery of six dead rats near to it.

TRAPS FOR NOXIOUS ANIMALS.

A good many years ago (some ten or twelve) the Society for the Prevention of Cruelty to Animals held a show or prize competition in the gardens of the Royal Horticultural Society, at South Kensington, of all the different kinds of traps that were in use for trapping, taking or killing noxious animals, the aim of the Society being of course to distinguish and reward those that occasioned least suffering to the animals taken. If the animals had had a voice in the matter they would no doubt have said that the Society for Prevention of Cruelty would have kept more within its *role* had they refrained from encouraging traps at all; they were not consulted, however, and the show duly took place. No doubt its results, that is, the names of the manufacturers and the traps that gained

Fig. 1.

the prizes were duly chronicled in the journals of the day, but we remember regretting that there was no general account nor figures of the different kinds of traps exhibited, which would have been not only a very useful record of what was available for the purpose, but also a very interesting display of human ingenuity turned in rather an unusual direction. It would also now have helped to show whether we have made any progress in the improvement of this class of articles dur-

Fig. 2.

Fig. 3.

ing late years — a point on which we feel considerable doubt, for we observe that whenever we have occasion to buy anything of that kind, the merchant rather dwells upon its being an excellent old-fashioned trap that has never been surpassed than on something with the fresher charm of novelty. We wish the Society for Prevention of Cruelty would hold another show for traps, which might be better utilized. In the meantime we shall notice one or two kinds which we have lately

Fig. 4.

seen exhibited or noticed in France, and as coming most home to the horticulturist, we shall begin with one or two contrivances for catching insects. The first is for catching the Mole-Cricket, an insect which, although very destructive to some plants in some parts of France, is not sufficiently numerous here to require much trapping.

The *Courtilière* or Mole-Cricket (fig. 4) is an orthopteron insect of large size, like the cricket and grasshopper. Its hind thighs are swollen for jumping, but the animal is heavy and makes somersaults, falls, and tumbles rather than leaps, and, indeed, does not often use this method of progression. It is of a dark rust colour, and has its anterior feet widened into delving shovels like the hands of the mole, to which its manner of digging and slightly raising the soil above its runs has much resemblance. In order to catch these animals, pieces of wood are taken in which holes $1\frac{1}{2}$ in. in diameter are

turned lengthways (A A, fig. 1), and pening in the middle (C B). Two ends (A A) are therefore open, but a little round of thin sheet iron (fig. 2) is suspended at each from above and opening inwards (L M, fig. 3). A part of the slightly raised passage hollowed by the animal under the earth is then uncovered, and the piece of wood is placed lengthways in such a way that its hole coincides well with that of the passage; all is then covered with earth. During the night, the Mole-Cricket, in visiting its passages, meets the little trap-door which makes a slight obstacle to it (fig. 4). It pushes against it, lifts it, and passes; the trap-door falls, and it is taken! Another arrives by the same road, or by the opposite extremity; it enters and meets the first; then, in this little dark and narrow space, a blind duel takes place; the conqueror devours the conquered. A third bandit arrives in his turn, who, fresh and active, immediately engages in battle with the conqueror, who is weakened and perhaps wounded in the preceding combat, and gives no quarter. In this way several Mole-Crickets are destroyed in the same night in the same trap, but never more than one whole one and the remains of some others are found within it. Such habits would hardly indicate that the Mole-Crickets are eaters of roots; and on the strength of them some hold that they are carnivorous, and that if they cut the roots, it is in order to catch the worm or the insect which attacks them. This is a very interesting point in the natural history of the animal—but it has not so much practical importance as might at first sight be imagined. If the bulbs of the *Gladiolus* for instance be destroyed by the Mole-Cricket, it is no consolation to the cultivator to be told that the insect that did the damage is a friend and to be cherished. But the evidence is too strong against them to allow us to doubt that, whether they be carnivorous or not, they are certainly vegetable feeders.

It is said that with thirty traps, which only cost a trifle (for any one may make them for himself), and with a little patience and skill, the most numerous colony of Mole-Crickets may be wholly destroyed in a few weeks. A. M.

A Plague of Cockchafers.—Many of the Departments in the north of France are, according to the "Globe," suffering from a plague of cockchafers, and the destruction made by them is becoming very serious. These visitations are of almost periodical recurrence, once in three years being generally the time when they make their appearance in overwhelming numbers, and the country people have at last adopted the expression of *l'année des hannetons* for the year in which they are expected. The destruction of small birds by the French sportsmen is asserted to be the cause of this scourge, which has reached alarming proportions. For the last few weeks during the evening the noise of the flight of these insects from tree to tree has been most extraordinary, the sound being like that of the whirl of machinery, and the leafless appearance of the trees shows the extent of their depredations. Commencing on the topmost branches they strip off every particle of verdure, gradually descending, until in many instances they leave the trees as bare as in midwinter. In some of the rural districts a few years back large sums of money were spent by the authorities in trying to get rid of these pests. In one small village in Normandy, called Varangeville, no less than £20 was paid for their destruction. The country people found the offer of one halfpenny a gallon a sufficient inducement to go out and collect them, which was effected by spreading sheets under the trees and then shaking them, when the cockchafers fell in thousands, were collected in baskets and carried to the Mairie, where, after they had been measured, they were buried in pits filled with quicklime. Some idea of the enormous quantity of the insects may be conceived when a reward of £20, the utmost the authorities were disposed to offer, was gained by the destruction of no less than 10,000 gallons of cockchafers. The mischief does not end with the results of their appearance in the winged form, but the grubs of the insect are equally destructive, and many a crop is seriously injured in the intermediate years of their appearance in such vast numbers. Of late the rooks and crows have received protection from the Government, and the result has in a measure been beneficial, but to all appearance it will take a long time before the pest is cured, and the small birds once more obtain the mastery. No greater proof than this instance in France could be afforded of the wisdom of the law to protect small birds, especially in the breeding season, as this scourge in France may ere long, if not checked, rival in extent that of the famous Colorado beetle.

THE INDOOR GARDEN.

EVILS OF EXCESSIVE PROPAGATION.

THE demand for unlimited numbers of soft-wooded plants for flower garden decoration has not only almost driven out of cultivation many of our old garden favourites, but indirectly it has used up or exhausted many of those that were but a few years ago the chief ornaments of our geometrical gardens. Verbenas and Calceolarias especially have suffered greatly by the excessive strain which has been put on the powers of reproduction, for being of a half-hardy character, the forcing process, to which they have been subjected year after year, to induce soft, succulent growth fit for the propagating pit, has eventually deprived them of their stamina or constitution, and, as a natural consequence, diseases of various kinds have made their appearance, all of which may be classed under the general term of premature decay. On the other hand, seedlings of these plants grown under exactly similar conditions flourish with surprising luxuriance, a circumstance which shows the evil cannot be attributed to soil or climate. There cannot be a doubt that many choice new plants are seriously affected by over-propagation before they reach the hands of the public; for, in getting up a stock of any new plant for which there is a great demand, the stock plants are forced to the utmost limits in order to produce cuttings, and not only new plants, but old ones, for which the demand is great, are propagated until the weight is diminished to so great an extent as to allow one of the peculiar features of modern gardening to be carried out, viz., the transmission of plants by post. The surprising part of the matter is that cultivated plants can endure such treatment; for I question if even our commonest weeds, however tenacious of life, would do so if subjected to a high temperature and every shoot cut off as fast as it made a pair of leaves. Any plant that flourishes in a temperate climate must, sooner or later, suffer from the enervating effects of a moist and warm temperature. It would be a gain to horticulture generally if we could be induced to recognize the truth of the statement, "Thus far shalt thou go and no farther"—for, by attaching an exaggerated importance to unseasonable productions, much valuable time and skill are wasted. It is no unusual thing to hear of people really fond of gardens being deterred from owning and cultivating one by exaggerated notions regarding the expense attending it; but if really useful and necessary subjects were cultivated first, and only spare time and money devoted to curiosities, we should seldom or never hear a complaint as to a garden being an unprofitable investment.

J. GROOM.

Heathum.

THE POINSETTIA AND ITS CULTURE.

THOUGH this plant has been in the country for forty years or more, it is still a comparatively rare thing to see it well flowered, if that term can be applied to a plant in which the flowers themselves are insignificant, its beauty consisting in the brightly-coloured floral leaves which, under good culture, crown the shoots. It is an easily-grown subject, and I do not know any winter-flowering stove plant that I could better recommend to large and small growers alike who possess a stove, or even an intermediate-house. The speediest way of propagating all the varieties of the Poinsettia is by cuttings made of the young shoots. It is not desirable to have the plants too tall, and consequently cuttings should not be put in before June, from which date successional batches may be struck every three or four weeks till October. This will ensure a stock of plants suitable for decorative purposes, of heights from 3 ft. to 6 in., and all will continue to flower from November till April or later. It has been stated that the Poinsettia cannot be had in flower so late as May; but I can state that at the beginning of that month this season I had numbers of plants of it in flower, though past their best, and even on the first of June bracts quite fresh and well-coloured were still hanging to the plants here and there, and in some instances the young growths, of which I have been making cuttings, are showing flower again; but the flowers do not appear as if they would come to much. In striking the cuttings the great point is to

take care of the tender foliage till roots are formed, after which the plants are safe. For the special purpose of striking a stock of Poinsettias, I have a small glass frame, about 2 ft. square, placed inside the house in which the plants are grown. It is set on a bed of sand, where the bottom-heat is about 80° or 85°, and is filled with small 3-in. pots, containing a light, sandy compost, when a batch of cuttings is to be taken off, and they are made and dibbled in, one in a pot, straight off, and the frame shut down close, or nearly so, till they are rooted, which takes about a fortnight. I never take the cuttings off with a heel, as is usually recommended, but always at the third joint, where the wood is soft and tender, and they root without fail—never a cutting damps off. The close, moist frame and tolerably high top and bottom-heat keep the leaves fresh; in fact, they never cease growing, and roots are soon formed. When they are fairly struck, more and more air is given, till in a week or so the plants are lifted out of the frame, and, after standing for a few days on the bed of the stove, in order to harden them off a little, they are potted in their flowering pots at once. For single plants, 5-in. pots are used, and when several plants are put together, the pots are a little larger. This is for the earliest plants, struck now, and which make from 3 ft. to 4 ft. of growth; for the later-struck plants smaller sizes are used, till I get to 3 in. and 4 in. for small single plants, which flower when only a few inches high. Last winter some that were rooted in September flowered when not more than 2 in. high, showing that taking the tops off when they are just showing flowers and striking them at that stage in order to have dwarf plants, is not at all necessary; though the plan is frequently resorted to, with the result generally of lessening the size of the crown, which is checked when just in the course of development. It is far better to strike the cuttings later in the season, and grow them steadily on till they flower. The best compost for the Poinsettia is a mixture of light, fibry loam, leaf-mould, sand, and a little well-rotted manure. The whole should be rather light, for the roots do not take kindly to a heavy soil. After the plants are potted from their cutting pots, they should be grown in a stove or other structure where a night and day temperature of 75° and 85° respectively can be afforded them, according to the weather, and they should be shaded from strong sunshine. If practicable, it is better to give them a pit or part of one to themselves during the season of growth, like other subjects of which a stock is grown; but if the general stove only be available for the purpose, they must be placed where they will receive plenty of light and air. The fault of the Poinsettia is that it is apt to lose its foliage if not cared for, and then half its beauty is gone. The foliage is very ornamental and luxuriant, and much enhances the beauty and value of the plant when used for house decoration. Provided the pots have been well drained—an important matter—water, of the temperature of the house, should be applied freely to the roots during the growing season; but as winter approaches a little discrimination is necessary to avoid making the soil sour by giving too much, otherwise the roots rot, and the plant droops and the leaves soon drop off. At least, overwatering and deficient drainage appear to be the causes of the Poinsettia disease, which is much like that which affects the Calceolaria. Every season some of the plants go off suddenly just when they are in flower. In order to develop the bracts properly, the plants must have a tolerably high temperature throughout the winter, say from 65° night to 75° by day, except when the weather is very severe, when the night temperature may be lowered 4° or 5°. After the crowns are fully developed the plants may safely be transferred to a cooler house, but not to a cold greenhouse, to harden them a little, after which they will endure the temperature of rooms for a long while, either in a cut state or in pots.

CHIEF.

A Useful White Heath.—Wherever Heaths are grown for purely decorative purposes, the kind called *Erica candidissima* will be found invaluable. It is one of the easiest to manage, is not subject to mildew, grows with great freedom, and if after the growth is finished the plants be placed in some sheltered, partially shaded position in the open air for a few weeks to ripen their wood, every little twig will be covered with pure white bell-shaped flowers, which are invaluable for bouquet making, as when mounted on wire they keep long in a fresh condition.—E. HOBDAK.

TREES AND SHRUBS.

THE GIANT ARBOR-VITÆ.

(THUJA GIGANTEA).

THIS rapid-growing, hardy, and graceful Conifer was introduced into Britain in 1854 from California, where it is said to grow to a height of 150 ft. Its foliage is glossy and of a lively green colour. The branches which alternate at irregular distances on the stem are tapering and pliable. The stem itself is erect, forming wood freely from the base upwards, and judging from its appearance it bids fair to become valuable as regards timber, which is said to be fine-grained and durable. It is used for building and other purposes by the Indians and colonists on the coast of North America, and the natives also manufacture the inner bark into various useful materials. It is called by the colonists the yellow Cypress, the wood being of a yellow colour. This Thuja has been widely and extensively distributed since its introduction, and has proved to be one of the most useful of evergreens for forming screens and shelter hedges, either for shutting out unsightly objects, or for warding off rough winds. It is a suitable and ornamental plant with which to adorn a lawn or pleasure ground, and no Pinetum should be without specimens of it. It is also valuable when planted to form an ornamental arbour, its long flexible branches admitting of being bent and trained to form an arch with but little trouble, and when tall bushy plants are used a living evergreen arbour may be established almost at once. It is one of the easiest of Conifers to transplant; indeed, with care it will succeed when moved at almost any season of the year: it is at home, too, in all kinds of soils, and it is thoroughly hardy. Now that it may be bought tolerably cheap, it would perhaps be worth while to introduce it into newly formed plantations with a view to test it in the future as a timber tree for commercial purposes. The tallest specimens in this country with which I am acquainted are from 35 ft. to 40 ft. high; if any of your readers possess taller trees, records of such would be interesting. Of this tree there are at least two distinct varieties in the trade; one is of an erect-growing habit with brighter green foliage than that of the type, the other is a variegated variety. Conifers, however, never look more beautiful than when of a true self colour, say either green, glaucous, or golden. Weeping Conifers, too, are desirable; I am not aware that there is a weeping form of this Thuja in the trade; I, however, possess one. It was discovered amongst other Thujas in our nursery about eight years ago: it is

now 12 ft. high, its branches are long and horizontal; the branchlets, which are from 12 in. to 15 in. long, hang in a true pendulous manner; in fact, many of them are quite vertical. This plant is, I think, destined to grow into a unique specimen.
G. B.

NOTES ON THE FRUITING OF THE HOLLY.*

BY JAMES M'NAB.

IN my report for the month of May (see page 528) I allude to the Holly as producing this year an amount of flower-buds rarely seen in the Botanic Garden, and the same seems to be general all

over Scotland, a circumstance probably owing to the trees not being exhausted last year, through fruit bearing. At this time (June 14) numerous blooms are open, and many of the plants white, some with fertile and others with non-fertile flowers, the latter in every instance being the most conspicuous. This mass of blossom must not, however, lead us into the belief that the trees will all be covered with fruit at Christmas; but a good crop I think may be looked for. Fertile and non-fertile trees being now easily recognisable (although not generally known), a few observations regarding them may not be unacceptable. Perhaps the most conspicuous of the fruit-bearing kinds now noticeable in a flowering condition consist of about one-third of the common green variety, nearly every plant of the varieties known as Hodgens' Holly, the Leather-leaved Holly, the Green Weeping and Moonlight Hollies, also all the large plants of the common variegated Golden and Silver Hollies, and many others. After a careful inspection of all the Hollies in the Botanic Garden, which now amount to many hundreds exclusive of hedges, I find that all those which we do know as annually producing fruit at Christmas are likely to be covered with fruit this year again (unless prevented by certain circumstances, concerning which there was much discussion last winter). On close inspection I find, as might have been expected, that

those Hollies, now covered with bloom, but on which no berries had ever been observed, possess stamiferous flowers only, while on all the known berry-bearing plants the ovule is generally far advanced before the buds are sufficiently open for fertilisation, and when they do expand, although all the anthers are formed, they appear abortive. The stamens in such flowers are all more or less curved backwards, while with the pollen-bearing plants, the stamens are all more or less upright, and densely covered with pollen, in such flowers the rudimentary female organ consists of a small barren, flattened ovary with four little projecting points on the apex, in all these cases the corolla always falls off entire, having the four upright stamens adhering to it, while in that of the fruit-bearing plants, the petals do not fall off entire, but break off into separate segments by the

The Giant Arbor-vitæ (*Thuja gigantea*).

* Read before the Botanical Society of Edinburgh, June 14, 1877.

gradual swelling of the young ovary. As I have not been able to find a single plant amongst all the original variegated Gold and Silver Hollies, bearing perfect stamiferous flowers, it is therefore evident that all these large variegated plants have been propagated originally from one stock, either by grafts, layers, or cuttings. The same observation also applies to the Hodgens' Holly, and the other pistiliferous kinds. Of recent years, variegated and other seminal varieties have been raised in various parts of the country, but none of the variegated forms have the robust character of the original sorts. It is therefore probable that both stamiferous and pistiliferous plant may be found amongst them, as instanced by the black-twigg'd silver-striped variety all being males. The blooms of the different named varieties vary much; perhaps those with the most prominent flowers, both for size and purity, are those produced on the Ilex Shepherdi, *I. nobilis*, and *I. atrovirens*, all of which are stamiferous plants, with large green leaves. The green Hedgehog Holly, and the variegated variety known as the Golden Queen Holly, with numerous others, are also stamiferous. In no instance have I been able to find a plant bearing flowers having both sexes complete on the same root. Owing, however, to the quantity of seedlings now raised, I do not see why this should not sometimes occur. In some cases a few solitary berries have been observed, but as such plants were not marked at the time, it is not easy now to distinguish them. Mr. Johnston, of the Lawson Company, has been kind enough to furnish me with the following list of Hollies now in a flowering condition in the Golden Acres Nursery, arranged under their respective heads.

Male Flowering Hollies.

<i>Ilex alicornis</i>	<i>Ilex ferox argentea</i>	<i>Ilex Silver Queen</i>
<i>nobilis</i>	" <i>aurea</i>	<i>robusta</i>
Shepherdi	<i>myrtifolia major</i>	<i>laurifolia aurea</i>
<i>angustifolia</i>	<i>ovata</i>	Wateriana
<i>ciliata major</i>	<i>serratifolia</i>	<i>pieta</i>
<i>crispa</i>	<i>pectinata major</i>	Golden Queen
<i>ferox</i>		

Female Flowering or Fruit-bearing Hollies.

<i>Ilex grandifolia</i>	<i>Ilex pendula</i>	<i>Ilex Lawsoniana</i>
<i>heterophylla</i>	<i>rotundifolia</i>	<i>marginata</i>
" <i>magna</i>	<i>Whittingtoniensis</i>	<i>media pieta aurea</i>
Hodgensii	<i>pendula purpurea</i>	<i>balearica</i>
<i>laurifolia</i>	<i>angusti-marginata</i>	

Hollies, producing Male and Female Flowers on Different Plants, or nearly Allied Varieties.

Common Green Holly	<i>balearica nigrescens</i>	<i>aurantiaca</i> (Moonlight)
<i>marginata</i>		

The Tulip Tree (Liriodendron) at Home.—The articles on the Tulip tree in your paper suggest to me that a few notes from its native wilds might be of interest to your readers. The Tulip tree, or Poplar, as it is generally termed here, is one of our most common as well as most useful trees for ornament, shade, and lumber. Within the last decade, millions of fine specimens of this grand tree have been ruthlessly destroyed and cut into the lumber which constitutes the major part of many a cosy home. Timber is no object, and the destruction still goes on; portable mills are plentiful, and in a score or two of years this beautiful tree will have disappeared from our forests. It seems most congenial to hilly, broken land, where it attains its greatest size. The valleys and hills of the Ohio and Mississippi appear to be its native home. Wood, in his botanical works, gives an account of a tree 23 ft. in circumference at 4 ft. from the ground, and 125 ft. high, growing in Indiana. Years ago, when thousands of acres that are to-day in grass and grain were in their primeval woodland dress, broken only here and there by a small farm, there was a tree a mile or so from my (Kentucky correspondent of "Country Gentleman") father's house, in this county, 10 ft. in diameter, and 140 ft. high. Alas! the woodman spared not that tree, and this king of all its race has gone the way of all things earthly. Trees 4 ft. or 5 ft. in diameter are abundant. The kind known as White or Blue Poplar is very tough, and will not split; the Yellow kind makes good rails, shingles, &c., and above ground compares favourably with our best lasting woods, but will soon rot in the ground; it is one of our earliest to put forth leaves, which quickly grow to their full size; they are now (April 21) about one-third grown, and already make quite a shade. The flowers in dry weather accumulate several drops of honey on the petals and sepals, and are generally sought after by the average small boy, bees, and animals that have a sweet tooth. The Yellow Poplar grows rapidly from seed, and, where left alone, soon makes a beautiful shade-giving tree.

THE LIBRARY.

A HISTORY OF FERNS.*

THE veteran ex-curator of Kew Gardens seems determined to "die in harness," if we may use such an expression, for, in spite of failing sight, and the many difficulties which this must entail, we have here another book upon the subject of Ferns, to which we may truly say the author has devoted his life. From 1841 until the present time Mr. John Smith has written upon the subject of Ferns; his extensive Fern herbarium, which is now incorporated with the large collection of Ferns in the British Museum, was commenced in 1829; while, with regard to his connection with the cultivation of these ever-popular plants, Mr. Smith himself speaks as follows in the volume now before us:—"In 1823 the collection in the Royal Botanic Garden, Kew, came under my care; it then consisted of about forty hardy species, British and foreign, and about the same number of tender exotics, the latter dispersed in various hot-houses. In 1825 I arranged the tender ones in a group at the end of one of the then lean-to houses, the space they occupied being 12 ft. by 6 ft.; these formed the nucleus of the present great collection." Any one reading this, and visiting what Mr. Smith truly calls "the great collection" now in Kew Gardens, will find in it a striking illustration of the oft-quoted line, "What great events from trivial causes spring." We do not suppose that any one will think Mr. Smith "egotistical" in giving the particulars which he has set down regarding his connection with the study of Ferns; they are useful as showing that he has availed himself fully of the many opportunities which his connection with Kew has afforded him; and it is a matter of some regret that others similarly situated have not made an equally good use of their privileges. In the work before us Mr. Smith gives a general and comprehensive sketch of his arrangement of the genera of Ferns, with characters of the genera, remarks on their relationship to each other, and many other particulars. We doubt whether systematists will be much influenced by the proposed scheme; but it is interesting to have the ultimate views of so extensive an observer placed upon record, and the future historian of pteridology will find a reference to Mr. Smith's volume essential to a complete sketch of the subject. Not the least valuable part of the book are the thirty admirable plates from the pencil of Mr. W. H. Fitch, illustrating the characters of the tribes. As a work which appeals primarily to the botanist rather than the horticulturist, any detailed or critical notice of it in our columns would be out of place, but we can recommend it to the attention of our botanical readers.

History of a Flower Mission.†—This is a reprint, in a very small form, of the exhaustive article on flower missions by Miss Constance O'Brien, which appeared in THE GARDEN in March last. It will meet the wants of persons interested in flower missions, and is of a size suitable for enclosure in an ordinary envelope. It pleads the cause and explains the aim and working of flower missions in a full and clear way.

Nisbet's Garden Account Book (Fawcett, Sleaford) will be found useful by all who have to furnish a debtor and creditor account of what their gardens produce. It contains blank columns for vegetables, salads, herbs, tart fruits, fruits for preserving, dessert fruits, cut flowers and plants; also a weekly labour account, columns for ice, coal, coke, manure, sundries, memoranda, a balance sheet for the week, and weather table; also space for Covent Garden prices. A bill of what can be furnished is taken to the cook, house-keeper, and butler every morning; they put their mark against whatever they want, and indicate the quantities which they require, and from these bills the account book is made up weekly. This system has been practised by Mr. Nisbet for fourteen years, and during that time has given entire satisfaction.

Cut-leaved Walnut (Juglans regia laciniata).—This, as will be seen by the woodcut (see p. 95), is a tree of beautiful habit and moderate growth. The divisions in the leaf are very elegant, and give a kind of transparency to the foliage, which is very pleasing. It forms a beautiful lawn tree, and if judiciously pruned or stopped, it may be grown to assume any form required. It is a great favourite with me.—CHAS. LEE, *Hammersmith*.

* *Historia Filicium*; an Exposition of the Nature, Number, and Organography of Ferns. By JOHN SMITH, A.L.S. London: 1875.

† Odell & Ives, 18, Princess Street, Cavendish Square.

STAR-LIKE HAIRS ON PLANTS.

IN the interesting article on this subject which appeared in THE GARDEN of May 26, I find no reference to the very characteristic stellate hairs on the leaf of the Sea Buckthorn (*Hippophaë rhamnoides*). The modified cells with which the cuticle of this leaf is furnished differ markedly from the forms figured in the article alluded to, and are peculiarly instructive as adding a well-defined link to the chain connecting the single hair and the scale. I chanced to have in my possession a leaf of *H. rhamnoides*, which had been given me a few days previously by a botanical friend, and I send you a sketch of one

Stellate Hair of *Hippophaë rhamnoides*.

of its stellate hairs removed from the cuticle, and viewed by transmitted light with the aid of the microscope. It will be observed that whereas the hair of *Alyssum spinosum* differs from that of *A. alpestre* in possessing a larger number of rays, in the hair of *Hippophaë rhamnoides* the rays are so much multiplied and so closely packed that the scale-like appearance predominates, and the stellate form is only preserved at the tips of the rays, or at most for a distance of one-fourth of their length. The extreme diameters of several specimens which I measured ranged from one hundred to sixty-six parts of an inch, and in each of these little stars I counted from sixty to seventy rays. A $\frac{1}{2}$ -in. objective will be found sufficiently high for their examination. BOVERTON REDWOOD.

RARE HARDY AQUATIC PLANTS.

Thalia dealbata which grows so freely in the greenhouse tank would, I think, often succeed out-of-doors in the warmer counties if given, a sheltered and sunny position. Some plants which I tried out-of-doors in a running stream made a more vigorous growth than I have observed them make in stoves, but they did not flower; I have,

Thalia dealbata.

however, noticed it flowering in Austria in a not very warm district. Would some American reader of THE GARDEN kindly say how far north it grows well there? I have succeeded perfectly with the *Helonias* in water—a beautiful thing; and I am trying the *Nelumbium speciosum*, which I have reason to believe is much hardier than is generally supposed. V.

Double African Lily.—This interesting form of an old garden favourite has lately been introduced by Mr. B. S. Williams, of the Victoria Nurseries, Holloway, where it is now in flower. Its precise value, as compared with the old form, cannot yet be stated, but it will probably last longer in flower and commend itself to many as worthy of trial.

SOME POINTS IN BOTANICAL NOMENCLATURE.

PROF. A. DE CANDOLLE has addressed a letter to M. A. Cogniaux, of Brussels, in answer to one from that botanist requesting his opinion on certain points connected with botanical nomenclature, and the correspondence is published in the "Bulletin" of the Belgian Botanical Society (t. xv., p. 477). The special cases stated by M. Cogniaux have reference to the proper authority to be appended to the names of species under the following circumstances which frequently occur:—1st. When an author finds a new genus on an old species, but does not actually place the new generic name in combination with the old specific name. 2nd. When an author enumerates several already known species as referable to a genus, either new or old, but (as before) does not give the combinations of names to designate each species. 3rd. When an author reduces one or more genera to synonyms under another genus, and the species of the former thus becomes species of the latter. In all these cases ought the new combinations of generic and specific names, which result from carrying out the ideas of the authors, to be followed by their names, as authorities?

M. De Candolle's reply is prefaced by some remarks which appear very just and pertinent. He recalls to mind, what is too often forgotten, that the mention of an authority after a name is not an homage rendered to the author; it conveys neither praise nor blame, and is in no way connected with the merits of botanists; it is simply a reference. He observes that "most of the names made by an author may fall into synonyms, whilst his reputation may remain immense if he has shown himself exact, clear, judicious, and profound. On the other hand, the author of bad descriptions is placed in the lowest rank of botanists, though, either from an accident of time or because he has adopted the genera of a good author, his names may stand. He considers that the true principle which ought to decide all such cases as the above is this: "Never to make an author say that which he has not said."

Tried by this canon the answer to the question asked in relation to the above difficulties will be a negative one, for in no case has the author published the new combination necessary to characterise a species, and to attribute such to him is to make him say what he has not said. In the first case, what the author has done is to refer a species to a new genus and to make a generic name. He has not said whether or not he approves of keeping up the old specific name; perhaps on farther consideration he would have rejected it, because he would have considered it to contradict the characters of the new genus, or because in his view it ought not to be admitted in the old genus. In the second and third cases, instances are quoted showing how unjust it might be to attribute to an author specific combinations of names which he has never actually made. It would then frequently happen that an author would be made responsible for far more species than he allows to constitute his genus; whilst in other cases, where there has been a union of several genera, great confusion would arise from two or more very different plants bearing the same name. In this latter case it is impossible to know what names the author would have kept up or proposed, and he ought not to be cited for names which he must have in part rejected. A point worthy of special note in the matter is this: that M. De Candolle assumes, as a basis of his argument, that an author who transfers a species to another genus is in no way bound to adopt the specific name which it previously bore. These views of the distinguished botanist of Geneva appear to be based on so solid and just an appreciation of the real bearings of the question, that they will probably commend themselves to all engaged in systematic botany. The practice in this country, however, at present, especially with the Kew school, is partially inconsistent with the plain rule above given.—"Journal of Botany."

A House-top Garden.—The roof of a house might in many cases be made a pleasant place. In the East the people live a great deal on house-tops. There is no reason why we should not utilize our house-roofs in some way in this country. They might be converted into gardens, conservatories, aquaria, or anything of the kind, giving additional room to a house, as well as an additional charm. The Americans are beginning to utilize house-tops in this way. The plan has been carried out at the Palmer House, Chicago (according to the "Farmer"), and a portion of the roof of that hotel is now covered with a magnificent conservatory. The structure is entirely of glass and iron; and as it is built on an extension, its location is such that it is entered directly out of the fifth floor corridor of the main edifice, which rises two stories above. A fine collection of tropical and rare plants has been provided, and the regular heating apparatus of the house supplies ample warmth. The conservatory is open to guests of the hotel, and furnishes a delightful resort. In this country the plan of garden roofs has been ably advocated by Mr. Eassie, in his popular little book, "Healthy Houses."

LOW'S NECKLACE VANDA.

(VANDA LOWI).

This species is one of the most distinct of all the Vandas, and, although as yet not common, it has several times bloomed and been exhibited in this country. Although a strong-growing plant it flowers in a comparatively small state, as is shown by a flowering specimen of it, which was exhibited at a recent meeting of the Royal Horticultural Society, by Mr. Elliott, of Clapton. The plant attains a height of from 2 ft. to 10 ft., and has distichous, leathery leaves, 2 ft. or more in length. We have other Vandas from Malaysia of similar habit, notably *V. Batemani*, from the Philippines, which grows in co-partnership with the glossy-leaved *Cypripedium levigatum*. There are one or two characteristics about Low's Vanda, however, possessed by no other species. The flowers are arranged on a slender, zigzag raceme, which not infrequently attains a length of from 6 ft. to 8 ft., and when furnished with buds somewhat resembles an elegant necklace, finally changing to a wreath of gold and purple-blotched blossoms, as shown in the annexed engraving, with the trifling exception that the slender flower-stem is densely hairy or hispid and not smooth as therein represented. Perhaps the most singular point in the history of this curious plant, however, is the production of flowers of two distinct kinds on one spike. At the extreme base of the flower stem, say 1 ft. or more from the leaf-axil whence it emerges, two flowers are produced at about 3 in. or more apart. These flowers are golden-yellow, the blotches being very small and scarcely visible, and having moreover a delicate perfume; then comes a space of 12 in. or 15 in., and then the ordinary flowers, the petals of which are rather broader than the basal yellow flowers, and are heavily and richly blotched with crimson-purple. This production of two distinct sorts of hermaphrodite flowers on the same spike is, however, only one of numerous instances of the kind now known to botanists. The spikes, which are often longer than the plant which produces them, occasionally trail along the ground, thus forming a ladder to nectar-hunting beetles and other insects, just as do the long-tailed petals of *Cypripedium caudatum*, or the singularly bearded inflorescence of *Attacia cristata*. The plant, which is one not at all difficult to cultivate, is propagated by means of offsets, which sometimes make their appearance on strong specimens.

Low's Necklace Vanda (*V. Lowi*).

PLATE LXXIX.

AGALMYLA LONGISTYLA.

This miniature creeping Gesnerad is a native of Java. From its peculiar habit it is well adapted for particular positions; when suspended from the roof in a stove, where plants of small growth can with advantage be used, it gives a more furnished appearance to the structure without injuriously shading the other occupants, and such a situation appears to suit it well and favours the free production of bloom. Like most other plants the time of its flowering is considerably influenced by the course of treatment to which it is subjected,

but, it is generally in perfection during the latter months of the year, a time when its scarlet or bright red flowers are very effective; they are comparatively large for the size of the plant which when well grown produces them freely. Being of a creeping habit, the stems cling closely to any surface on which it is grown, not unlike the rhizomes of some Ferns, such as the weaker-growing *Davallias*; the leaves, which are produced on short stalks, are ovate in shape and have a velvety appearance. It may be cultivated in a pot, but as it is a true Epiphyte it does best on a block of wood, in which way it can be better hung up, and as we have comparatively few subjects of a similar character and so suitable for the purpose, it is well to utilize it in this way; its flowers in such a position are also seen to the best advantage. As regards culture I procure a rustic-looking piece of dry Oak wood about 6 in. wide, 1 ft. in length, and 2 in. in thickness; if charred it will look none the worse and will last longer, a consideration in the case of such plants as this that have clinging roots that adhere tightly to whatever they fasten upon, and cannot be removed without injury; fix a copper wire by means of copper nails to each end of the block to hang it up by, cut a piece of good fibrous Orchid peat about an inch thick and the same size as the block; shake as much of the earthy matter out of it as can be done without breaking it; fasten it on the upper surface of the block with fine copper wire; shake a handful of silver sand over the part, which will help to keep it from getting sour; then take a plant that has been either grown in a pot, or cut several of the creeping stems with several leaves to each, and tie them with wire or bast on the surface of

the peat; give water immediately, and shade until the roots have got hold; these operations should be performed in March before growth has commenced. All through the growing season the roots must be kept moist, and even in winter they must never be allowed to get too dry. During spring and summer the night temperature should range from 70° to 75°, and from 80° to 85° in the daytime. In winter it may vary from 60° to 70° and a few degrees higher in the daytime. The shoots require little training, simply bending about in such a way as to cover the block. As soon as the flowers make their appearance do not allow more water to lodge upon them than can be avoided. It is a heat-loving subject, and neither when in flower nor at any other time should it be submitted

Onosma echioides.—While walking over the Karsa in the neighbourhood of Sesana in the Austrian Tyrol, I was much pleased to find a lovely *Onosma*, which I think will prove to be the true *O. echioides*, a plant I believe not in cultivation. It is very similar in general appearance to *O. taurica*, but it has white flowers instead of yellow. Perhaps some of your correspondents may have seen it, and can tell me whether it is the true *O. echioides* or not.—A. Z. P.

Barke's Tree Fern (*Cyathea Barkei*).—A tree of rare grace, which may now be seen growing freely in Mr. Williams' Victoria Nursery, at Holloway. This is one of the finest of the arborescent Ferns yet discovered, and will probably succeed in the temperate fernery. The stems are stout and erect, bearing a rich head of deep green fronds, which are twice or three divided, and which have a graceful pendulous habit. Native of South Africa.—H. H.

THE SCARLET FOOT BLOSSOM *AGALMYLA LONGISTYLIS*.

to a low temperature, or cold draughts. With me the plant was never at any time attacked by insects. T. BAINES.

WREATHS FOR DEAD WALLS.

So long as we have dead walls, some means of modifying their severity is desirable. In landscape gardening the dead wall is often a serious obstacle to deal with, and, indeed, so it is in the small garden. In these, however there is sometimes a necessity for the dead wall as a dividing line or a screen, whereas in large country places they are often made where they are needless and objectionable. In small gardens the dead walls, usually bare along the top, may be gracefully wreathed with either climbing shrubs or fruit trees, as shown

in the accompanying cut. Single stems are easily taken up the wall and trailed along two or three firmly fixed, but slender galvanised wires. In this way much of the harsh aspect of the upper part of the wall is removed, and in the case of fruits more tangible advantages result. The accompanying sketch was made on the road from Vincennes to Montreuil, a country in which good Grapes are gathered on the trellis; ornamental subjects for such wires are numerous enough from Wistaria to Clematis montana.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 498).

Onions.

- (1) *Bottom*. And most dear actors, eat no Onions nor Garlick, for we are to utter sweet breath.
Midsummer Night's Dream, act iv., sc. 2.
- (2) *Lafeu*. Mine eyes smell Onions, I shall weep anon:
Good Tom Drum, lend me a handkercher.
All's Well That Ends Well, act v., sc. 3.
- (3) *Enobarbus*. Indeed the tears live in Onion that should water this sorrow.
Antony and Cleopatra, act i., sc. 2.
- (4) *Enobarbus*. Look, they weep,
And I, an ass, am Onion-eyed.
Ibid., act iv., sc. 2.
- (5) *Lord*. And if the boy have not a woman's gift
To rain a shower of commanded tears,
An Onion will do well for such a shift,
Which in a napkin being close conveyed
Shall in despite enforce a watery eye.
Taming of Shrew (Introduction).

There is no need to say much of the Onion in addition to what I have already said on the Garlick and Leek, except to note that Onions seem always to have been considered more refined food than Leek and Garlick. Homer makes Onions an important part of the elegant little repast which Hecamede set before Nestor and Machaon:—

Before them first a table fair she spread,
Well polished and with feet of solid bronze;
On this a brazen canister she placed,
And Onions as a relish to the wine,
And pale clear honey and pure Barley meal.
Iliad, B. xi. (Lord Derby's Translation).

The name comes directly from the French *oignon*, a bulb, being the bulb *par excellence*, the French name coming from the Latin *unio*, which was the name given to some species of Onion, probably from the bulb growing singly. It may be noted, however, that the older English name for the Onion was *Iue*, of which we may perhaps still have the remembrance in the common "Inions." The use of the Onion to promote artificial crying is of very old date, Columella speaking of "lacrymosa caepe," and Pliny of "caepis odor lacrymosus." There are frequent references to the same use in the old English writers.

Orange.

- (1) *Beatrice*. The count is neither sad nor sick, nor merry nor well; but civil count, civil as an Orange, and something of that jealous complexion.
Much Ado About Nothing, act ii., sc. 1.
- (2) *Claudio*. Give not this rotten Orange to your friend.
Ibid., act iv., sc. 1.
- (3) *Bottom*. I will discharge it either in your straw-coloured beard, or your Orange-tawny beard.
Midsummer Night's Dream, act i., sc. 2.
- (4) *Bottom*. The ouzel cock so black of hue
With Orange-tawny bill.
Ibid., act iii., sc. 1.
- (5) *Menenius*. You wear out a good wholesome forenoon in hearing a cause between an Orange-wife and a fossot-seller.
Coriolanus, act ii., sc. 1.

I should think it very probable that Shakespeare may have seen both Orange and Lemon trees growing in England. The Orange is a native of the East Indies, and no certain date can be given for its introduction into Europe. Under the name of the Median Apple a tree is described first by Theophrastus, and then by Virgil and Palladius, which is supposed by some to be the Orange, but as they all describe it as unfit for food, it is with good reason supposed that the tree referred to is either the Lemon or Citron. Virgil describes it very exactly—

Ipsa iugens arbor, faciemque simillima lauro
Et si non alium late jactaret odorem
Laurus erat; folia haud ullis labentia ventis
Flos ad prima tenax.—*Georgic* ii., 131.

Dr. Daubeney, who very carefully studied the plants of classical writers, decides that the fruit here named is the Lemon, and says that it "is noticed only as a foreign fruit, nor does it appear that it was cultivated at that time in Italy, for Pliny says it will only grow in Media and Assyria, though Palladius in the fourth century seems to have been familiar with it, and it was known in Greece at the time of Theophrastus." But if Oranges were grown in Italy or Greece in the time of Pliny and Palladius, they did not continue in cultivation. Europe owes the introduction or re-introduction to the Portuguese, who brought them from the East, and they were grown in Spain in the eleventh century. The first notice of them in Italy was in the year 1200, when a tree was planted by S. Dominic at Rome. The first grown in France is said to have been the old tree which lived at the Orangery at Versailles till November, 1876, and was called the Grand Bourbon. "In 1421 the Queen of Navarre gave the gardener the seed from Pampeluna; hence sprang the plant, which was subsequently transported to Chantilly. In 1532 the Orange tree was sent to Fontainebleau, whence, in 1684, Louis XIV. transferred it to Versailles, where it remained the largest, finest, and most fertile member of the Orangery, its head being 17 yds. round." It is not likely that a tree of such beauty should be growing so near England without the English gardeners doing their utmost to establish it here. But the first certain record is generally said to be in 1595, when (on the authority of Bishop Gibson) Orange trees were planted at Beddington, in Surrey, the plants being raised from seeds brought into England by Sir Walter Raleigh. The date, however, may be placed earlier, for in Lyte's "Herbal" (1578) it is stated that "In this country the Herboristes do set and plant the Orange trees in their gardens, but they beare no fruite without they be wel kept and defended from cold, and yet for all that they beare very seldome." There are no Oranges in Gerard's catalogue of 1596, and though he describes the trees in his "Herbal," he does not say that he then grew them or had seen them growing. But by 1599 he had obtained them, for they occur in his catalogue of that date under the name of "Malus orantia, the Arange or Orange tree," so that it is certainly very probable that Shakespeare may have seen the Orange as a living tree.

As to the beauty of the Orange tree, there is but one opinion: its handsome evergreen foliage, its deliciously-scented flowers, and its golden fruit:—

A fruit of pure Hesperian gold
That smelled ambrosially.

Tennyson.

at once demand the admiration of all. It only fails in one point to make it a plant for every garden: it is not fully hardy in England. It is very surprising to read of those first trees at Beddington, that "they were planted in the open ground, under a movable covert during the winter months; that they always bore fruit in great plenty and perfection; that they grew on the south side of a wall, not nailed against it, but at full liberty to spread; that they were 14 ft. high, the girth of the stem 29 in., and the spreading of the branches one way 9 ft., and 12 ft. another; and that they so lived till they were entirely killed by the great frost in 1739-40."—(Miller). These trees must have been of a hardy variety, for certainly Orange trees, even with such protection, do not now so grow in England, except in a few favoured places on the south coast. There is one species which is fairly hardy, the *Citrus trifoliata*, forming a pretty bush, with sweet flowers, and small but useless fruit (seldom, I believe, produced out-of-doors); it is often used as a stock on which to graft the better kinds, but perhaps might be useful for crossing, so as to give its hardiness to a variety with better flower and fruit.

Commercially the Orange holds a high place, more than 20,000 good fruit have been picked from one tree, and England alone imports about 2,000,000 bushels annually. These are almost entirely used as a dessert fruit and for marmalade, but it is curious that they do not seem to have been so used when first imported. Parkinson makes no mention of their being eaten raw, but says they "are used as sauce for many sorts of meats, in respect of the sweet sourness giving a relish and delight whereinsoever they are used;" and he mentions another curious use, no longer in fashion, I believe, but which might be worth a trial:—"the seeds being cast into the ground in the spring time will quickly grow up, and when they are a finger's length high, being plucked up and put among Sallats, will give them a marvellous fine aromack or spicy tast, very acceptable."

Osier—(See Willow).

Oxlips.

- (1) *Perhita*. Bold Oxlips, and
The Crown Imperial. *Winter's Tale*, act iv., sc. 3.
- (2) *Oberon*. I know a bank whereon the wild Thyme blows,
Where Oxlips and the nodding Violet grows.
Midsummer Night's Dream, act ii., sc. 2.

The "bold Oxlip" (*Primula elatior*) is so like both the Primrose and Cowslip that it has been by many supposed to be a hybrid between the two. Dr. Hooker, however, considers it a true species. It is a handsome plant, and is a great favourite in cottage gardens.—(See Cowslip and Primrose).

Palm Tree.

- (1) *Rosalind*. Look here what I found on a Palm tree.
As You Like It, act iii., sc. 2.
- (2) *Hamlet*. As love between them like the Palm might flourish.
Hamlet, act v., sc. 2.
- (3) *Voluntio*. And bear the Palm for having bravely shed
Thy wife and children's blood.
Coriolanus, act v., sc. 3.
- (4) *Cassius*. And bear the Palm alone.
Julius Cæsar, act i., sc. 2.
- (5) *Painter*. You shall see him a Palm in Athens again, and flourish
again with the highest.
Timon of Athens, act v., sc. 1.

Two very distinct trees are named in these passages. In the last five the reference is to the true Palm of biblical and classical fame, as the emblem of victory, and the typical representation of life and beauty in the midst of barren waste and deserts. And we are not surprised at the veneration in which the tree was held, when we consider either the wonderful grace of the tree, or its many uses in its native countries, so many that Pliny says, that the Orientals reckoned 360 uses to which the Palm tree could be applied. Whether Shakespeare ever saw a living Palm tree is doubtful, but he may have done so—(see *Date*). Now there are a great number grown in the large houses and botanic gardens, the Palm-house at Kew showing more and better specimens than can be seen in any other collection in Europe; even the open garden can

now boast of a few species that will endure our winters without protection. *Chamaerops humilis* and *Fortunei* seem to be perfectly hardy, and good specimens may now be seen in several gardens; *Corypha australis* is so said to be quite hardy, and there is little doubt but that the Date Palm (*Phoenix dactylifera*), which has long been naturalized in the south of Europe, would live in Devonshire and Cornwall, and that of the thousand species of Palms growing in so many different parts of the world, some will yet be found that may grow well in the open air in England.

But the Palm tree in No. 1 is a totally different tree, and much as Shakespeare has been laughed at for placing a Palm tree in the forest of Arden, the laugh is easily turned against those who raise such an objection. The Palm tree of the Forest of Arden is the Early Willow (*Salix caprea*), and I believe it is so called all over England, as it is in Northern Germany, and probably in other northern countries. There is little doubt that the name arose from the custom of using the Willow branches with the pretty golden catkins on Palm Sunday as a substitute for Palm branches.

In Rome upon Palm Sunday they bear true Palms,
The Cardinals bow reverently and sing old Psalms;
Elsewhere those Psalms are sung 'mid Olive branches,
The Holly branch supplies the place among the avalanches;
More northern climes must be content with the sad Willow.
Goethe—(quoted by Seeman).

But besides Willow branches, Yew branches are sometimes used for the same purpose, and so we find Yews called Palms. Evelyn says they were so called in Kent; they are still so called in Ireland, and in the churchwardens' accounts of Woodbury, Devonshire, is the following entry:—"Memorandum, 1775. That a Yew or Palm tree was planted in the churchyard, ye south side of the church, in the same place where one was blown down by the wind a few days ago, this 25th of November."

How Willow or Yew branches could ever have been substituted for such a very different branch as a Palm it is hard to say, but in lack of a better explanation, I think it not unlikely that it may have arisen from the direction for the Feast of Tabernacles in Leviticus xxiii., 40:—"Ye shall take you on the first day the boughs of goodly trees, branches of Palm trees, and the boughs of thick trees, and Willows of the brook." But from whatever cause the name and the custom was derived, the Willow was so named in very early times, and in Shakespeare's time the name was very common. Here is one instance among many:—

The Palms and May make country houses gay,
Lambs frisk and play, the shepherds pipe all day,
And we hear aye birds tune this merry lay—
Cuckoo, jug-jug, pee-we, to-witta-woo.

T. Nash—1567-1601.

Pansies.

- (1) *Ophelia*. And there is Pansies—that's for thoughts.
Hamlet, act iv., sc. 5.
- (2) *Lucentio*. But see, while idly I looked on,
I found the effect of Love-in-Idleness.
Taming the Shrew, act i., sc. 1.
- (3) *Oberon*. Yet marked I where the bolt of Cupid fell:
It fell upon a little western flower,
Before milk-white, now purple with love's wound,
And maidens call it Love-in-Idleness.
Midsummer Night's Dream, act ii., sc. 2.

The Pansy is one of the oldest favourites in English gardens and the affection for it is shown in the many names that were given to it. The Anglo-Saxon name was Banwort or Bone-wort, though why such a name was given to it we cannot now say. Nor can we satisfactorily explain its common names of Pansy or Pawnee (from the French, *pensée*—"that is, for thoughts," says Ophelia), or Heart's-ease, which name was originally given to the Wallflower. But besides these more common names, Dr. Prior mentions the following:—Love in Idle or Idleness (a name still remaining in Warwickshire, and signifying love in vain, or to no purpose, as in Chaucer—"The prophete David seith; if God ne kepe not the citee, in ydel waketh he that kepith it"), Herb Trinity, Three Faces Under a Hood, Fancy, Flamy, Kiss Me, Cull Me or Cuddle Me To You, Tickle My Fancy, Kiss Me Ere I Rise, Jump Up and Kiss

Me, Kiss Me at the Garden Gate, Pink of My John, and several more of the same amatory character."

Spenser gives the flower a place in his "Royal aray" for Elisa—

Strove me the grounde with Daffdowndillies,
And Cowslips, and Kingeups, and loved Lillies,
The pretie Pawnee,
And the Chevisaunce
Shall match with the fayre Flower Delicee.

Milton places it in Eve's couch—

Flowers were the couch,
Pansies, and Violets, and Asphodel,
And Hyacinth, earth's freshest, softest lap.

He names it also as part of the wreath of Sabrina—

Pansies, Pinks, and gaudy Daffadils.

and as one of the flowers to strew the hearse of Lycidas—

The White Pink and the Pansie streaked with jet,
The glowing Violet.

Parsley.

Biondello. I knew a wench married in the afternoon as she went to the garden for Parsley to stuff a rabbit.

Taming of Shrew, act iv., sc. 4.

Parsley is a common name to many umbelliferous plants, but the garden Parsley is the one meant here. This well-known little plant has the curious botanic history that no one can tell what is its native country. It is found in many countries, but is always considered an escape from cultivation. Probably the plant has been so altered by cultivation as to have lost all likeness to its original self.

Peach.

(1) *Prince Henry.* To take note of how many pair of silk stockings thou hast, viz. these, and those that were thy Peach-coloured ones!

2nd Henry IV., act ii, sc. 2.

(2) *Clown.* Then there is here one Master Caper, at the suit of Master Threepile the mercer, for some four suits of Peach-coloured satin, which now peaches him a beggar.

Measure for Measure, act iv., sc. 3.

The references here are only to the colour of the Peach blossom, yet the Peach tree was a well-known tree in Shakespeare's time, and the fruit was esteemed a great delicacy, and many different varieties were cultivated. Botanically the Peach is closely allied to the Almond, and still more closely to the Apricot and Nectarine, indeed, many writers consider both the Apricot and Nectarine to be only varieties of the Peach. We are probably indebted to the Romans for the introduction of the Peach into England. It occurs in Archbishop Ælfric's Vocabulary in the tenth century, "Persicarius, Perseoc-treow," and John de Garlande grew it in the thirteenth century, "In virgulto Magistri Johannis, pessicus fert pessica." (When I mentioned John de Garlande before, I ought to have stated that his garden was probably in the neighbourhood of Paris; but he was a thorough Englishman, and there is little doubt that his description of a garden was drawn as much from his English as from his French experience).

We all know and appreciate the fruit of the Peach, but few seem to know how ornamental a tree is the Peach, quite independent of the fruit. In those parts where the soil and climate are suitable, the Peach may be grown as an ornamental spring-flowering bush. When so grown preference is generally given to the double varieties, of which there are several, and which are not by any means the new plants that they are generally supposed to be, as they were cultivated both by Gerarde and Parkinson.

H. N. ELLACOMBE.

(To be continued).

Double Yellow Auricula.—Last spring I grew this Auricula side by side with the Double Yellow Bedford variety of it, to test which is the better one, and the latter proved to be very much superior to the former. On one truss all the blooms died off before opening out, but that one for size and doubleness was quite a marvel.—G. F., *Hexham*.

Crinum ornatum Hardy in Ireland.—This stately hardy Amaryllid (for so it has proved itself to be in the open border at Glasnevin) is very precocious in producing its floral umbels; so much so that the past month has seen it in and out of flower there. It will continue to send up flower-stems at intervals during the season till winter comes.

THE FLOWER GARDEN.

HOSE-IN-HOSE POLYANTHUSES.

IN your issue of the 5th ult. (see p. 354) you insert some observations from "A. D." respecting a new golden Hose-in-hose Polyanthus. I am the originator of these yellow Hose-in-hose Polyanthuses. The yellow colour was obtained by a Polyanthus of large size, but quite plain (I forget its name); upon that I crossed the old White Hose-in-hose, which produced several Hose-in-hose seedlings of a straw rather than a yellow colour. I worked into this the yellowest Cowslip taken from the field, and about twenty years ago I obtained a fine deep yellow, which I named Henry Wooler. Some years since I gave Messrs. Backhouse a few plants of this, and two years ago I forwarded to Mr. T. Ware, of Tottenham, some plants with other Hose-in-hose sorts raised from Henry Wooler and other plants crossed by pollen from Henry Wooler, of a deep yellow and gold colour. The only stipulation I made was, that as this Hose-in-hose strain had been raised by me at my uncle's, it should be sent out in his name, viz., as "Henry Wooler." I have now got the strain so fixed that I should think 50 per cent. of the seedlings from a Hose-in-hose will come so. The late Mr. Beaton's flat contradiction (in one of the horticultural journals some nineteen or twenty years ago) that seed of a Hose-in-hose would produce one of the same breed, led me to grow plants in pots separately, and thus made to flower early, upon which I applied the pollen of Henry Wooler; from the seed thus grown many Hose-in-hose were the result, and some few even of yellow colour.

I send you a box containing a few I am growing with one of Henry Wooler, having no doubt but that they will prove of interest. In my opinion there is no spring flower which makes one-half the display and lasts so long as the light and gay-coloured Polyanthus, and my beds have often been the admiration of old florists. This year they have not done well, having been planted in poor cold clay; but the proper mode of cultivation is to sow the seed in boxes as soon as ripe; winter in frames; in spring, prick out into beds, with some rather rich soil, overlaying a cool bottom, and the brightness of colours and vigour of the plants in the following spring will be a source of wonder and delight; some of course will flower in the year they are pricked out. I also send a flower of another seedling I raised about twenty years ago, and which I named Sadberge. Of this I have given plants to Messrs. Backhouse and Mr. Ware.

In my opinion the great aim as regards the raising of Polyanthuses should be to obtain a semi-double breeder, in order that we might have a race of double Polyanthuses. The one "A. D." named is a very old one. We have several charming gems in double Primroses raised by our ancestors (why cannot their posterity do the same?). I have upon several occasions made efforts to secure a strain by selecting those with anthers converted into petalets, and I fancy it would be as well also to try the pollen of these on plants which produce their ordinary petals crimped, and more than the normal five, but I have not a great reliance upon these latter, as in some plants the same disposition to produce excess of petals is directed into increased size of the petals, and not a multiplication of them. There can be no doubt that when a Polyanthus converts an anther into a petalet, it is concentrating its force to produce the first stage as to doubling its flowers. Some years ago I suggested that the flowers of Cowslips and Primroses should be collected and left to decay into soil, and in that state supplied to seedling Polyanthuses with the express object of feeding the plants with the elements exceptionally demanded to form petals. This suggestion was derided at the time by the editor of one of the leading horticultural papers, but my few experiments on this head left a strong impression on my mind that it did produce the effect I expected. It is a well-recognized experience that certain food and position, together with other conditions, have a marked physical power in producing certain effects, not only upon plants, but upon ourselves, and what is needed to produce a multiplicity of petals is that the proper food and conditions shall be provided. No doubt in doubling flowers a condition is often found in checking too luxuriant a growth of the woody stems of the

plants (we all recognize this in root-pruning our fruit trees), but every race of plants has its idiosyncrasy and constitutional proclivities. I have a single Primrose which in the years 1875 and 1876 produced on one side of the plant two or three flowers with an anther grown into a petal; this year I divided it, but I have not yet seen any such. Last year I had several seedlings crossed with the pollen from this plant with these petals, but I fear the seeds were not collected separately.

I made a suggestion in one of the gardening journals several years ago that if one of the double Primroses could be, by starving in bad soil, induced to revert partly to a single state, so that the style might be impregnated, a race of semi-double breeders might be obtained. At least a quarter of a century ago Mr. Wood, of the Norwood Nursery (who, all old lovers of hardy flowering plants will recollect, was in the habit of exhibiting at the Royal Horticultural Society's shows such incomparably-grown batches of hardy plants in pots), gave me a fine, double, buff-coloured Polyanthus, as he thought it would receive more attention from me than he could give it. Unfortunately I kept it too tenderly, and it was thus lost. Mr. Ivery, the then well known nurseryman, who grew and let out several new Indian Azaleas at that time, gave it to him, and stated, I think, that it had come by chance in an old garden border at Reigate. There must have been some conditions in that old border to have forced the mother plant to produce seed which developed the anther and pistil of the plant into petals and so become double, or, as in the case of my Primrose, an anther or two were thus formed into a petal, and produced seed which produced the double-flowered plant. I got a very curious seedling last year, a yellow Hose-in-hose with a flat flower-stem. It was divided into seven plants, all of which have come true. This stem is very short, with a very large truss, and the leaves grow round a centre in a very regular manner.

W. A. WOOLER.

[The specimens sent were very interesting and of great beauty—a whole family of Hose-in-Hose Polyanthus, differing strikingly in hue, size, and form, and many of them likely to be of much value as garden plants.]

NOTES ON GARDEN VEGETATION FOR MAY.*

By JAMES McNAB.

THE weather in May, particularly the early part of it, has been rather cold and backward. During the first eight days 36° of frost were registered. The lowest markings were on the 2d, 3d, 4th, 5th, 7th, and 8th, when 21°, 32°, 26°, 26°, 28°, and 24° were respectively indicated; while the six highest morning temperatures were on the 17th, 19th, 20th, 21st, 25th, and 30th, when 44°, 42°, 41°, 41°, 44°, and 45° were indicated—all being below the maximum temperatures noted during May, 1876. The wind, with a few trifling exceptions, kept in the east, but changed to the west on the 24th, and since that time vegetation has made progress, which, however, was slow owing to the dry state of the atmosphere until rain fell copiously on the 28th, which did much good. As long as the wind was in the east the foliage had a great struggle to develop itself, and it was remarkable to observe the peculiar yellow tinge of the young leaves of many deciduous trees, contrasting singularly with the dark green of the neighbouring evergreens. Judging from the state of the trees and herbaceous plants on the 31st of May, this season may be regarded as one of the latest which we have had for many years; indeed, I do not recollect ever experiencing one so backward. Still averaging about three weeks late up to the end of the month, the only species of deciduous trees on which the foliage could be said to be nearly complete were the Acer Pseudo-Platanus and the common Hawthorn; that of many others was advancing, but far from complete. For comparison with future years I shall give a list of some of the ordinary trees and the state they were in on the 31st of May; these, however, vary in different situations and exposures. Besides the Plane and Thorn just alluded to, Lime trees were only partially in leaf, and those chiefly on the south and west sides. On a few Beeches the leaves were partially expanded, but many very backward; Birch trees were covered with catkins, but none of the leaves were fully developed. Leaves were also seen on the Norway Maple, Horse Chestnuts, and Purple Beech, but much later than usual, while the Elm, Walnut, Chestnut, Sorbus, Lombardy, and other Poplars, Willows, Oak, Ash, and Sugar Maple were all very backward, some only breaking their buds, while no foliage was observed on the

Robinias, Celtis, Ostrya, deciduous Magnolias, Tulip trees, Platanus, Taxodium distichum, &c. On the 31st of May, with the exception of the Plane and Thorn just alluded to as being in leaf, and those where no foliage was visible, most of the intermediate ones, from the small state of the young shoots and buds, had a peculiar network appearance, light being seen through every twig and leaf, a sight rarely observable in this part of the country at such an advanced period of the year.

Besides forest trees it may be remarked that many dwarf, shrubby, and herbaceous plants have been also very late in flowering, and where this is the case it will be observed that their duration in a perfect flowering condition is often shorter than when flowers come forth at the natural period. This is particularly noticeable in the case of such plants as Menziesia cœrulea, M. empetriformis, Bryanthus erectus, Andromeda tetragona, &c., as well as in that of many herbaceous plants which usually bloom between the middle and end of April, and which present a much gayer appearance than they do when late in flowering. With reference to the ordinary garden herbaceous plants, kinds which we usually trust so much to for class illustrations, very few of those sorts generally used during May could be had in flower. A long list of such plants might be given; a few, however, will suffice for future comparison, viz., *Doronicum Pardalianches*, *Geranium phœum*, *Aquilegia vulgaris*, *Potentilla ræpestris*, *Heracleum giganteum*, *Scabiera montana*, *Astrantia major*, *Papaver orientale*, also *Lupines*, *Thalictrums*, *Pœonias*, *Aconitums*, and *Delphiniums*. By May 31 we generally have flowers on the Horse Chestnuts, *Pavia flava*, *Laburnums*, *Lilacs*, *Common and Red Hawthorns*, *Bird Cherries*, and also on some varieties of *Sorbus*. This year we have only had the Double Cherry, Gean, Perfumed Cherry, Crab Apple, and Norway Maple in bloom. It will be remembered that Holly bushes last winter were nearly destitute of berries, and that various causes were assigned for the failure. This year blossom-buds may be seen in the greatest abundance, but few on May 31 were expanded. In my garden notes for May, 1875, I find it stated that Hollies of every description were covered with blossom so that the surface of the ground beneath them was white with the fallen flowers, and a good crop of berries was the result. During May last year flowers were also produced in abundance; the severe frosts (26°) which occurred during that month, and which was general all over the country, and at a time when the Holly blossom was in perfection, must have injured the pollen to such an extent that little or no fruit was produced. Although the frost during May of this year was more severe than last year, the Holly buds were not sufficiently advanced to be injured, and it will be well on in June before they can be fully developed, when it will afford a good opportunity to botanists to examine the flowers in different stages and in different situations, as well as in different varieties, and thus satisfy themselves as to the hermaphrodite or non-hermaphrodite state of these plants.

On the rock garden 212 species and varieties of plants were more or less in bloom on May 31. It will be needless to record a list of all. The following selection may be useful to those wishing to cultivate a set of plants for flowering at this particular time of the year:—

<i>Andromeda fastigiata</i>	<i>Ledum thymifolium</i>
<i>Andromeda tetragona</i>	<i>Lithospermum prostratum</i>
<i>Anemone alpica</i>	<i>Menziesia cœrulea</i>
<i>Anemone palmata</i>	<i>Menziesia Drummondii</i>
<i>Anemone Pepiana</i>	<i>Menziesia empetriformis</i>
<i>Aretostaphylos alpina</i>	<i>Polygala Chamæbuxus</i>
<i>Aretostaphylos californica</i>	<i>Phlox setacea violacea</i>
<i>Aubrietia Hendersonii</i> , and others	<i>Primula ciliata purpurata</i>
<i>Azalea procumbens</i>	<i>Primula cortusoides amœua</i>
<i>Bryanthus erectus</i>	<i>Primula integrifolia</i>
<i>Coptis trifoliata</i>	<i>Primula involucrata</i>
<i>Daphne Cneorum</i>	<i>Primula luteola</i>
<i>Dodecatheon integrifolium</i>	<i>Primula Pedemontana</i>
<i>Draba tridentata</i>	<i>Primula scotica</i>
<i>Dryas Drummondii</i>	<i>Pulsatilla vulgaris</i> var.
<i>Dryas octopetala</i>	<i>Ranunculus parnassifolius</i>
<i>Erica hypernica alba</i>	<i>Ranunculus unicolor</i>
<i>Erica hypernica stricta rubra</i>	<i>Rhodothamnus Chamæcistus</i>
<i>Erythronium americanum</i>	<i>Salix lanata</i>
<i>Gentiana verna</i>	<i>Salix reticulata</i>
<i>Helonias bullata</i>	<i>Saxifraga peltata</i> , and many others
<i>Helonias bullata alba</i>	<i>Trifolium unicolorum</i>
<i>Hutchinsia alpina</i>	<i>Trillium grandiflorum</i>
<i>Iris cristata</i>	<i>Viola pedata</i>
<i>Ledum buxifolium</i>	

Meconopsis nepalensis.—This is a stately Poppy from the Himalayas, allied to the well-known Welsh Poppy (*M. cambrica*), but with pale sulphur flowers of rather thin texture. The erect stems, 2 ft. to 3 ft., are many-flowered, and the blooming begins at the top, as is usual with these Himalayan species.—B.

* Read before the Botanical Society of Edinburgh, June 14, 1877.

RENOVATING GRASS LAWNS.

It is astonishing how long a lawn will retain its verdure without assistance in the way of manure. No doubt a lawn gets impoverished in time by being continually cut; but still it seems to sustain little or no injury. The roots of Grass appear to be endowed with an extraordinary vitality, and the rains to which they are exposed recoup them for the close cropping to which they are subjected, and perhaps the fact of the Grass never being allowed to seed has also something to do with maintaining fertility. The vitality of Grass roots is best exhibited in dry seasons. In the dry summer of 1868 I knew large trees to die through drought at the root, and many to be seriously injured; but though the lawn was as brown and dead-looking as if it had been scorched by fire, the Grass was not killed. I thought it was in many places, for to all appearance the roots appeared shrivelled up, as well they might be, being close to the surface, and the Grass having been kept as closely shaven as a carpet

anything better than this for Grass, and its effects are more lasting than guano or soot alone, and it may be applied without fear of injury. Should the lawn be Mossy, it should be well harrowed with a rake first, and then cleaned and dressed. C.

A Piece of Old Time Gardening.—Under one of the cascades at Caserta there is a very large covered way with well-constructed rocky walls and walks, through which, Niagara-fashion, the visitor, who ought to be very much astonished, makes his way. In this covered way the Maiden-hair Fern is everywhere growing luxuriantly between the rocks and stones. From these shady places, however, it ventures out into crevices in the heads of the sea-monsters, thus protesting, as it were, against such a monstrous use of moustons.

“Gardening” at Caserta.

till the drought came; but when the rains came in October it began to grow, and by next summer all traces of the drought had disappeared. It must not be supposed, however, that I approve of lawns being allowed to become exhausted; by no means. A starved sward is never a very green one, and greenness and freshness are everything in a lawn; and upon the whole it is not difficult to keep it in that condition, for however neglected it may have been, it quickly responds to stimulating treatment. The best and most convenient plan is to apply artificial manure of some kind in the form of a top-dressing. Guano is good, but it does not produce the greenest verdure; soot surpasses it in that respect, and it is cheaper. It is not needful to top-dress the lawn annually, and when necessary most gardens should provide the materials. If all combustible rubbish in the way of prunings of trees, rakings of shrubberies, &c., be collected into a heap, they will serve not only to consume themselves, if set fire to, and produce a good quantity of wood ashes, but will reduce to ashes all the short Grass that has come off the lawn, weeds, roots, and other rubbish, and at the same time burn a considerable quantity of soil, which may with advantage be mixed with the ashes and the whole applied to the lawn as a top-dressing. There is hardly

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Henchera Menziesi.—This graceful little plant is blooming very beautifully here this season. It does remarkably well in a shady bog bed, and is well worth growing.—J. WHITTAKER, *Crewe Hall*.

Ferns and German Irises Intermixed.—Few plants are more suitable for small gardens than the blue-flowered German Iris; it thrives in almost any soil, and never fails in spring to produce abundance of large showy blossoms. Hardy British Ferns, too, will grow freely in similar situations, and in spring they throw up fresh green fronds just at the time that the Irises are in bloom. I lately saw Ferns and Irises growing together among large stones under a shady wall in a villa garden at Clapham, and the effect produced by the intermixture was excellent.—S. C.

Begonia Froebelli out-of-doors.—In addition to this Begonia being one of the best for planting out in beds, it forms an excellent plant when grown in a cool house and in good sandy soil. Even small bulbs of it throw up abundance of long flower-spikes, which commence to bloom as soon as they have attained 6 in. in height, and continue to grow and flower for many weeks at a time. If allowed plenty of light and air the blossoms when open are of the most brilliant scarlet, contrasting well with the stiff, deep green Cineraria-like leaves. Good plants of this Begonia recently flowered freely in Mr. Hudson's garden at Clapham, where they are grown in front of a cool Vinery.—S.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vinerics.—There is nothing that the amateur so frequently fails in as late Vines; by such I mean those that are grown in houses that are without any means of applying fire-heat; or, if such exist, where it is not employed to accelerate growth in the spring, and the Vines are simply left to begin growing by the influence of sun-heat. It is with these that amateurs, especially new beginners, more often fail than with anything else they attempt to cultivate, not that the Vines refuse to grow if the soil in which their roots are placed be of fair quality and efficiently drained, and the foliage be kept in healthy condition and free from insects. The cause of non-success is through their not showing fruit, on account of the wood being insufficiently matured the previous season. In a season like the present, when even under glass everything that has not been brought on by the assistance of fire-heat is more than ordinarily late, the mishap of insufficiently ripened wood is more than usually likely to occur, especially with Vines that are strong and vigorous. Our summers are generally hot enough to supply the requirements of the Vine when grown under glass, but very frequently are not of sufficient duration, for in such late springs as the present, although the fruit may ripen before the foliage begins to go off in the autumn unless fire-heat has been applied to the Vines in the spring to forward the growth or will be employed in the later stages of their development, it is necessary to hasten the maturing process by unremitting attention in closing the lights sufficiently early in the afternoons whilst the sun is on the glass in order to secure a strong heat for some hours. No time can be fixed for closing, as the state of the weather and position of the house will naturally affect the condition of things; for instance, a lean-to house, with a south-eastern aspect, or where the sun's rays are at all obstructed by any other building, will need to be closed much earlier than a similar structure with a southern or south-western aspect fully exposed, but no harm need be feared by heat that will cause the thermometer to run up to 90° or even a little over, when at the same time there is sufficient moisture in the atmosphere, which can be effected by copiously watering the floors and walls at the time of closing. Vines that were started with heat in the spring early enough to have the bunches in a condition to thin a short time ago, should be examined again to see that the berries are not too much crowded, or more bunches left on than the Vines can bear without distressing them. The latest crops will now be ready for thinning, and should be attended to without delay. As I have before recommended, it is a much safer plan for the repression of that most injurious pest red spider, to syringe the Vines overhead, at all events, up to the time when the berries have stoned, and are commencing their second swelling.

Lawns, &c.—Mow lawns and verges sufficiently often to preserve a neat appearance, as when the Grass is allowed to get too long without cutting, instead of saving it entails more labour. During the summer months mowing machines should be set so as to leave the Grass half an inch longer than earlier in the season and late in the autumn; this is especially needful where the land is dry, and the roots of the Grass are liable to be burnt up. Cut away the tops of Crocuses and Tulips as soon as they have turned yellow, but not before.

Flower Garden.—Should the weather continue dry attend regularly to watering, so as to get the beds well furnished without delay. Where carpet-bedding is carried out, and the different varieties of Alternanthera are used, unless the soil has been made very rich (they will bear it to consist of one-third of rotten manure), they will be benefited by manure-water, made with horse-droppings or a little guano; for unless these plants are liberally supplied with manure in some shape, either solid or liquid, they do not grow nearly so strong, and fall as they ought, nor are they so well coloured.

Peaches and Nectarines.—Though these on open walls this year are in very few places carrying enough fruit to tax the powers of the trees to support it, yet nothing should be left undone to prepare them sufficiently for another year. In very light soils Peaches frequently do not succeed well, the trees often dying or getting into an unhealthy condition whilst comparatively young. There is no doubt that a moderately strong loam suits them the best; yet, if their requirements as to water be properly supplied, they can be kept for a long time in a healthy state in comparatively light ground, but without it this is impossible, as the Peach, more than any other fruit, cannot endure dryness at the roots. It is during the latter part of this and the next two months that in most summers they need an abundant supply of water. Where the borders slope considerably water always has a tendency to run off; but, if the surface be loosened with the hoe about 2 in. deep (not more, or it

will interfere with the roots), and on this (provided the ground is not cropped with anything else) are laid 2 in. or 3 in. of half-rotten littery manure well saturated with water, the trees will be benefited by the manurial elements thus washed down to their roots; and, should other crops be on the ground, the above mulching laid between the rows will stop evaporation, and help the soil to retain moisture much longer. Where the subsoil happens to be of an open nature, such as gravel or sand, it is difficult to keep Peach trees in a healthy condition without some such provision. If Peaches be allowed to suffer from drought during the middle of summer it not only inflicts permanent injury, but is often the cause of failure in the crop during the ensuing season, as when the growth is checked thus early, and there is an abundance of rain about the end of August, it starts the trees again into growth, after which there is not sufficient time for the formation of strong and plump fruit-buds. Continue to syringe the trees freely twice a week with clean water to keep down aphides and red spider, the former of which I have found very much more troublesome this year than usual. Continue to attend to the Peach borders under glass, so as to see that they are moist enough at the time the fruit begins to ripen, after which it will be necessary to keep the soil drier until after the fruit is gathered, for if too wet during the latter stage of maturation the flavour will be materially affected.

Strawberries.—In treating upon Strawberry culture, it is generally assumed that they are planted in strong, heavy land, as that is the best adapted to this fruit; but the soil of many gardens is of a light sandy nature, not calculated for the best raising of Strawberries without especial attention, and which (even in a season like the present, when the superabundant rains through the autumn and winter have rendered the land sufficiently moist for the requirements of vegetation) will need a plentiful supply of water; as now, whilst the fruit is swelling, the energies of the plants are taxed to the utmost, and if deficient in moisture at the roots, the produce of the crop will not be satisfactory. It should ever be remembered that in applying water, especially to a crop like this, one good soaking is much more effectual than several insufficient applications.

Kitchen Garden.—Advancing crops of Carrots should be again looked over to see that they are not left too thick, especially the main sowing. Turnips also will require attention in this respect; there are few crops suffer so much as this if allowed to stand too close together, as when in this state they run to leaf, forming bulbs that are not only small but very poor in quality. Put in more seed, the early sowings in the majority of places having been unsuccessful. Beet.—Thin the main crop before the plants get so large as to interfere with the growth, as, without we have a more than usually protracted summer, there is much less time than usual for them to grow to a useful size. Coleworts.—Some seed should now be sown; these will be useful for planting thickly late in the season after other crops are cleared off. In respect to this vegetable it is necessary that amateurs should make sure that they get the seed true and not some small kind of Cabbage which is sometimes substituted for it, as the Colewort will turn in its leaves and make useful heads when planted later than any variety of Cabbage; it also may be planted under fruit trees when these are not grown too close. Of course they will not produce anything like the crop they will in an open situation; nevertheless, what they do yield is so much gain, and they help to keep down weeds. Beans.—Where Dwarf French Beans are held in particular estimation a few more may at once be sown; these should occupy a south border, under the shelter of a wall, where, by a slight additional protection from September frosts they will frequently go on bearing longer than those grown in more open situations. Cabbage.—Planted Cabbages that have been cut and the stools left to produce a crop of Sprouts, should, where the land is at all poor or of a light nature, have a good soaking with manure-water, by which, in addition to thinning out the shoots to some two or three to each stool, they will make small, useful heads, that will come in through the autumn. Keep the hoe going on all favourable occasions amongst advancing crops of every kind.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

June 25.—Potting Anne Boleyn Pinks. Putting Cockscombs into their flowering pots. Planting out some old Pink plants that have been forced; also Stocks, Asters, Perillas, Veitch's Autumn Giant Cauliflower, Snow's Broccoli, Savoys, and Scotch Kale. Potting Lycopods in boxes for the conservatory. Leaving abundance of

air on Peach-house in which the fruit is ripening. Layering Straw-berry runners in small pots, and earthing up French Beans.

June 26.—Potting off young seedling Carnations. Shifting large Colens into larger pots. Sowing Maclean's Wonderful Pea, Round Spinach, and White Dutch and Golden Ball Turnips; also French Beans and Lettuce. Digging land in which to plant another crop of French Beans. Removing laterals from Vine shoots, and regulating the shoots of Peach trees in houses; also nailing Apricot, Plum, and Peach trees out-of-doors. Emptying a pit for Cucumbers, and placing large standard Heliotropes in conservatory.

June 27.—Basketing *Oncidium cheiroporum*, using peat and crocks, and potting *Masdevallia Veithei* and *coccinea* into 6-in. pots. Planting out newly-struck Pink and Carnation cuttings. Wheeling in manure for Celery trenches. Keeping floors of Vineries where fruit is swelling frequently watered. Digging all vacant ground and hoeing between growing crops. Tying in all leading shoots in Peach-house, and also those of espalier Pear and Apple trees out-of-doors.

June 28.—Shifting *Achimenes* into their flowering-pots; also dwarf *Chrysanthemums*. Netting Strawberries, and layering runners of plants from which the fruit has been gathered. Digging ground lately occupied by Lettuce for French Beans, adding plenty of well-rotted manure. Thinning Turnips. Syringing Ferns for thrips and green fly. Throwing out and manuring more trenches in which to plant *Canlidowers*.

June 29.—Sowing dwarf China and Negro Long-pod French Beans; also various kinds of Endive. Planting Broccoli amongst Potatoes. Plunging Roses that do not require repotting. Thinning Salsafy, Scorzonera, and Turnips. Putting old forced bulbs that have been well dried in flower-pots and storing them away. Leaving a little air on Vinery all night where Grapes are changing colour. Thinning out the shoots of Tomatoes, regulating the remaining ones, and nailing them to the wall.

June 30.—Putting large standard Heliotropes into their flowering pots. Shifting scented Verbenas into 8-in. pots to grow on for cutting purposes. Potting Arum Lilies, Gesneras, and *Justicias*. Staking out *Cattleya Mossiæ* and *C. speciosissima*, and putting them into smaller pots. Sowing Nonpareil Peas and main crop of Endive. Thinning Carrots. Watering Vines and Peach-house. Pegging down Verbenas and *Petunias* in flower garden. Gathering Sir J. Paxton Beans from under hand-lights.

Hardy Flowers.

AUBRIETIAS.—Some find these difficult to propagate; my practice is to pull off all the straggling side-shoots now from the old plants, securing as much stem as possible, and breaking it off close to the main root; then a piece of ground is dug in a cool, shady border, into which is worked plenty of rough sand and leaf-mould; the shoots are then planted in lines, a little sandy soil being placed about the portion put into the ground, and all is trodden down firmly. The cuttings are then occasionally sprinkled and kept shaded from the sun, and, thus managed, but few failures occur. One great advantage in getting the cuttings started now is that the plants become strong and dense by the end of the summer, and are well fitted for planting out. The best of the *Aubrietias* are *Campbelli*, *Eyresi*, *græca*, and the pretty variegated form of *deltoidea*; this requires careful treatment in the way of striking cuttings, which do best in pans of a light, sandy soil, kept moist and cool.

DIANTHUSES.—Among these there is the charming *D. alpinus*, dwarf in growth, and bearing large, deep rose-coloured flowers. I find it does best in pots in a gritty, sandy soil, and kept in a cool, shady place. *D. barbatus*, or the common Sweet William, is now blooming freely, and some of the improved forms are very beautiful. Sweet Williams generally are not sufficiently well cultivated, and the consequence is they fail to bloom so finely as they would do under better attention: I have seen some with flowers of great size and very handsomely marked. *D. superbus*, the flowers of which are deep pink and handsomely fringed, is a very valuable decorative plant, but sharing, to some extent, the prejudice which attaches to fringed flowers. It is now blooming with me in pots, and I am looking forward with some interest for the blooming of some seedlings. The showy annual *Dianthus*s, such as *D. Heddewegi* in particular, are beautiful both in borders and in a cut state. The latest selection is termed *D. diadematus*, the flowers of which are more or less handsomely marbled.

FOXGLOVES.—These look well as a background to mixed borders, associated with Larkspurs, Dahlias, Hollyhocks, and other tall-growing plants. I was looking over a bed of the improved varieties a few days ago, and very beautiful many of them are. Instead of only the ordinary purple and white kinds there can now be found

flowers with rose, lilac, pink, and blush exteriors, the blossoms large and of fine form, and the throat or lip very handsomely spotted. It is in this rich, bold spotting that the beauty of the Foxglove so much consists. The small brown spots, characteristic of our wild Foxgloves, have been converted into large, rich, dark blotches and spottings, and when these markings are in combination with pure white tubes, the effect is strikingly beautiful. Foxgloves are now getting into full bloom, and in the case of extra strong plants there is first the massive centre or main spike, and then a number of side growths come forth later. Those who do not require to save seed should cut out the centre spike as soon as it gets shabby, and the side-shoots will be considerably benefited thereby, especially if a good supply of water be given at the roots in dry weather. In the case of the best varieties a side-shoot will supply an abundance of seed. If the seed be sown early in spring the plants will become strong for planting out in autumn, and will flower the following June. A good yellow Foxglove would be acceptable; but seedlings from *D. grandiflora* or *D. lutea* do not show any material improvement on the parental type.

GLADIOLI.—Gladioli, whether in masses or grown singly, require attention during hot, dry weather. In the case of a bed of fine seedlings the surface has just been gently stirred, and a mulching of 2 in. of good manure laid over it. The bed is well syringed every evening, and the falling water carries down to the roots much of the invigorating properties of the manure. Some of the shoots are coming up remarkably strong, and they are already being secured to stakes to prevent them from being broken off by the wind. The following early-flowering species richly deserve a place in the mixed border, viz., *communis*, the flowers of which vary somewhat, being occasionally white, blush, or pinkish-rose; *G. cardinalis*, red; and *G. ramosus*, rose, of which there are some very beautifully-coloured varieties.

LATHYRUS.—Under this head we have the Everlasting Peas, among which *L. grandiflorus* is used largely for training on cottage walls, and it is already in full bloom in sheltered spots. It makes an excellent summer fence if planted against iron railings or anything of the kind that will afford it support; the flowers, which are of large size and handsome, are produced with great freedom; once planted, it will continue to grow up in spring and bloom in early summer for years. *L. latifolius*, the common Everlasting Pea, is so well known as scarcely to need mention, but it is, nevertheless, invaluable in gardens. *L. Drummondii*, the scarlet or carmine Sweet Pea, is much scarcer; it is extremely pretty, but requires to be somewhat in the shade, as the sun scorches its gay flowers and spoils their effect; like the others, it is propagated by seed and root division.

MIMULUSES.—*Mimuluses* in pots should now be in a cool north house, as hot weather, when the plants are fully exposed to the sun, is very trying to them. By keeping them cool and shaded, their beauty can be prolonged for a considerable time. Some seed sown now would yield plants that would bloom in August and September. Harrison's New Musk deserves a word of praise. The habit of growth and character of the common Musk are maintained, but the flowers are spotted, large, and handsome. Musk is greatly helped by being potted from 2 in. to 3 in. deeper than usual, and then gradually filling up the pots with rich soil as the plants make growth; in this way fine examples of Musk can be had. I am treating the new kind in a similar manner, and with good results. D.

Metropolitan Water Supply.—Dr. Frankland reports, as the result of his analysis of the waters supplied to the metropolis and some of its suburbs during April, that taking unity to represent the average amount of organic impurity in a given volume of the Kent Company's water during the last nine years, the proportional amount of this impurity in an equal volume of water supplied by each of the other companies, and by the Tottenham Local Board, was:—Tottenham, 0.5; Colne Valley, 0.9; Kent, 1.0; New River, 3.1; East London, 3.6; Lambeth, 4.7; West Middlesex, 5.3; Grand Junction, 5.7; Chelsea, 6.1; and Southwark, 7.8. All the water delivered from the Thames, except that supplied by the Middlesex Company was more or less turbid, and was unfit for dietic purposes, being much polluted with organic matter. The Southwark Company's water was "very turbid," repulsive in appearance, and contained "fungoid growths and moving organisms;" this company's filter-beds have been undergoing repair since the summer of 1876. The Grand Junction water also contained moving organisms. The water supplied principally from the Lea by the New River and East London Companies was very superior to the Thames waters, and was efficiently filtered. The deep well waters supplied by the Kent and Colne Valley Companies and by the Tottenham Local Board were of their usual excellent quality. The Colne Valley water is softened previous to delivery, and showed less than 5° of hardness, whereas in the Kent and Tottenham waters there were 25° and 27° of hardness respectively.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

LILiums, tall blue-flowered Larkspurs, white and yellow Alliums, and the double scarlet-flowered Geums, now rank amongst the most showy of hardy flowers. German, Spanish, and English Irises make, as a matter of course, a fine display. The blue *Anchusa italica*, in the form of large bushes, is just now very bright, and makes a good wild garden plant. *Onosma taurica* is laden with blossom, as is also *Muscari comosum grandiflorum*. Peruvian Squills, both blue and white, are still in good condition at Tottenham, where also may be found *Campanula Wanneri*, growing on

Fraxinella (*Dictamnus Fraxinella*).

rockwork, and bearing a profusion of handsome dark blue, bell-shaped drooping blossoms. The blue *Campanula alpina*, too, is just at its best, and forms an effective contrast with the brilliantly-flowered *Delphinium nudicaule*. Large bushes of the rosy-tinted white *Cistus albilorus* are also very showy, growing on mounds and other raised positions. *Æthionema grandiflora* now forms one of the most attractive of border-plants, and a pretty dwarf-growing *Spiræa* is flowering for the first time in the Tottenham Nurseries. Columbines of all colours are still in full bloom, and the bluish-purple flowers of the Alpine *Pentstemon glaber* is in

THE KITCHEN GARDEN.

THE SQUASH AND ITS CULTURE.

THE SQUASH is a tender annual of tropical origin, and it needs to be treated as such. Although a tropical plant it has the capacity of adaptation to a wide extent throughout the temperate zones, where its natural requirements are complied with. The reason why failure is so often met with in its culture is the neglect to recognize the origin and natural requirements of the plant. Apart from its tenderness, the seeds are liable to rot in the ground in continued damp and cold weather; therefore the planting should be delayed in spring until the ground gets properly dry and warm and the weather settled. Almost any soil is suited for the Squash, although for a good crop of fine-grained, well-flavoured fruit I prefer a sandy loam not too rich, but in fair heart. Plough and work the soil, as its nature may require; if a thin one, work it from 3 in. to 5 in. deep, a deeper one may be worked deeper, provided the soil be well drained. Make the surface even and soil fine by harrowing; then lay off the rows and hills as the variety may require. Make the excavations for the hills wide and deep, to hold two or more shovelfuls of manure, which should be well rotted. Cover it so as to be fully even with the surrounding surface; on this drop, scattering within a circle of 1 ft. in diameter, six to eight seeds, covering them with one-half to three-fourths of an inch of fine soil, and compressing with the back of the hoe. When the plants are well up, and have made their first rough leaves, thin out the weaker ones till finally there shall remain to grow only three, or at most four, the strongest and best. Cultivate sufficient to uproot weeds and keep the soil loose and mellow. When the plants run and begin to take root at the joints, be careful not to disturb them, as nourishment is taken up through these roots. Some pinch off the ends of the vines after they have made a growth of a few feet and blooming has commenced, with the impression that it promotes fruitfulness and early maturity, but in my own experience I have failed to find any material advantage in this.

In varieties we have summer, autumn, and winter, thus filling the seasons and year around. It is a very difficult thing to grow two or more varieties, which blossom at the same time, in the same field or its vicinity, without their becoming mixed, so that Squashes grown from their seed will partake of the character of each, or be very different from either. Sometimes this is the case when they are planted at a considerable distance apart, through the agency of insects carrying the pollen from one to the other. From this it will be seen that the growing and retaining of pure seed is a somewhat delicate business, and seeds are not to be depended upon where various sorts are grown in near proximity, or in the same field. If one wish to grow his own seed, he should plant only one variety, and at a considerable distance from any other of the same class of plants: and from the produce select the very best and most perfect specimens, and from these save seeds sufficient to plant for several seasons, as they will retain their vitality, when properly cared for, eight or ten years. By pursuing this course with different sorts, as many seasons as you may wish different varieties, just so many sorts of reliable seed may be obtained; or all may be grown the same season by planting each variety entirely alone and at considerable distance from any other of the same tribe. New varieties are easily produced—much easier than retained; but the production of a superior sort, combining all the desirable points, is a work of exceeding delicacy and patience. Sorts are selected possessing as many good points as possible, and these are cross-fertilized; these seeds are then separately tested, and when one is found possessing most desirable qualities, this is tested in different soils and localities till established as a distinct and desirable variety. Sometimes a "sport" will afford a desirable variety, and may be easily established by careful culture; but few cultivators have the time or patience necessary to the production and establishing of new varieties, and this is left to professional or amateur cultivators. Seeds of the Squash are saved from specimen fruits, washed clean, and then dried. On an extended scale the seeds and surrounding portions are scraped out together (after cutting the

Woolly Foxglove (*Digitalis lanata*).

Lebanon Candytuft (*Æthionema cordifolia*).

excellent condition, growing in warm, rich soil. The largest of all the Iberises (*I. gibraltaria*) is just now a mass of snowy whiteness. The Flame-flower (*Tritoma Uvaria*) is beginning to throw up its stalwart flower-stems, a circumstance doubtless attributable to the sudden advent of the bright, warm weather which we are now experiencing. *Oxalis lupinoides* is a mass of deep rosy blossoms, and the brilliant scarlet Sage-like flowers of *Anigossanthus splendens* are very attractive. *Gladiolus Histrion flore abla* is flowering freely, as are also plants of *Brodiaea congesta*, various *Ornithogalums* (especially *O. arabicum*), and *Polygonum undulatum*.

thoroughly ripened fruit in two) into a tub or cask; a quantity of water is added, and then allowed to stand and ferment, when the seeds will settle at the bottom. The fluid is then poured off, and the seeds washed by adding water, stirring and pouring off till the seeds look clear. They are then drained through a suitable strainer, and spread on sheets or cotton prepared for the purpose, and exposed to the air, being stirred daily till sufficiently dry, finishing off by spreading them 2 in. deep on a floor in some airy building. When perfectly cured they can be put in barrels or boxes, but will need changing two or three times a week from one receptacle to another, till settled cold and dry weather has set in. Seeds should be stored in dry, even-tempered rooms, where there is no chance of their absorbing dampness; dry wood or paper is suitable for packages. Sometimes seeds are injured by admitting steam, or even the air arising from some sweating material, into their compartment. Seeds are seldom or never injured by any atmospheric heat or cold, provided it be unaccompanied by moisture, and will keep stored thus their maximum time.

For summer varieties I can recommend only Summer Crookneck and Bush-scalloped; the first a limited runner, the other of dwarf, erect habit. The Crookneck is the better Squash in all respects for the table. The fruit of these summer Squashes is too well known to need description. Both are used while young and tender, as when old the skin becomes hard and shell-like. They also become watery, coarse, and unpalatable. The Crookneck may be planted in hills 6 ft. apart, and the Bush-scalloped 4 ft. each way, in large hills, with a heaping half bushel of manure to each hill, in garden culture. Among the autumn and winter varieties, the Autumnal Marrow is a good one; the plant is moderately vigorous, growing from 10 ft. to 12 ft. in length; fruit not large, ovoid, pointed at the ends; stem fleshy and large, somewhat contracted where it joins the fruit; skin thin, easily bruised; cream yellow at maturity, changing to red later; flesh, rich, salmon-yellow, quite dry, fine-grained, and remarkably sweet. In favourable situations it will be sufficiently grown for use in August, and will, under favourable circumstances, keep till March. The American Turban appears to be a sort of sub-variety of the original Turban, and in some respects is an improvement thereon. Compared with the original, the plant is somewhat hardier, and a more abundant bearer, a better keeper, and quite as rich and delicate. The Hubbard is vigorous; fruit irregularly oval, from 8 in. to 10 in. long, and from 7 in. to 8 in. in diameter, fair specimens weighing from 7 lb. to 9 lb.; outer shell hard and thick, covered with small protuberances; colour variable, clay-blue or deep olive-green; long exposure to sun causes the exposed side to assume a brownish cast; flesh rich salmon-yellow, and thick, fine-grained, sweet, dry, and of the best flavour. When baked it is equal to the very choicest Carolina Sweet Potatoes; it is sweetest and driest in autumn or beginning of winter, but will keep till June. It is more essential, if possible, that this variety be planted as far as possible away from any of its kind, as it mixes or hybridizes so readily. This Squash, I consider, has no superior in excellence for cooking purposes. The Yokohama runs to the length of 12 ft. or more; fruit roundish, much flattened at the ends, strongly ribbed; size from 8 in. to 10 in. in largest diameter; skin warted, yellow or dull orange at maturity; flesh orange-yellow, fine-grained, dry, and sweet. Will keep till March. The Canada Crookneck is somewhat similar in habit to the common Crookneck, but has smaller foliage, and less luxuriant in growth; size small, seldom exceeding 6 lb. in weight; skin moderately thin, easily pierced by the nail; colour, when mature, cream-yellow; age causes it to assume a deeper or darker colour; flesh salmon-red, very close-grained, dry, sweet, and fine-flavoured; best of the Crooknecks; plant very hardy.

Having said thus much concerning culture and varieties, it might be expected that I should say something concerning insects. Would that I could give new light, and speak with assurance concerning these insect enemies and their specific antidotes. But insect life is a problem not solved in a day. The striped bug and the black flea beetle are the most common, both working on the leaves of the plants and often destroying them. Various repellants have been suggested and tried to prevent their ravages; among which are ground plaster, air-

slacked lime in fine powder, soot, or charcoal dust sprinkled on and around the young plants; but the most effective preventive is to cover the plants with gauze stretched on a frame and placed over each hill. This is only practicable where only a few hills are grown, as in garden culture. In field culture we must rely upon numerous plants, and sprinkling with some of these repellants. Another enemy which destroys the young plants is the common cut worm, for which an effectual remedy is wanting. Stirring the soil and killing by hand is the surest, and exposing them for birds to pick up.

Squashes are gathered before frosts cut the foliage down, as they are very sensitive even to light frosts, which injure their keeping qualities. The fruits should be cut from the vines, retaining the stem entire, and be very carefully handled, not to bruise or otherwise injure them. When storing them, they should not be piled one on top of another, but should rather be laid singly. To keep them through the winter, they should be stored in a rather dry, even temperature, above the freezing point. A dry, well-ventilated cellar keeps them well, or a room aboveground, where frost does not enter, makes a capital storing place. Lay them singly, so that they do not touch each other (or any substance likely to mould), on dry boards covered with straw. Before being stored for the winter, they should be stored for a week or more in a barn, so that they may evaporate superfluous moisture, and then be placed in their straw beds, that will tend to absorb any farther evaporation. If the straw get damp and likely to mould, it should be changed for dry. We once knew a cultivator living in an old-fashioned house, containing an old-fashioned kitchen, with its huge fire-place and back-log, who used to keep the old Crookneck Squash in his kitchen, hanging on a peg fixed to a beam or joist overhead. He would frequently keep them sound till the summer following. I suppose any variety of Squash will keep its season when its requirements are similarly complied with. The essential requisites in keeping Squashes are to have them well matured without being chilled by frost, perfect specimens, and moisture evaporated before being put away, and then stored in a safe, even temperature, where they will neither mould nor absorb moisture.—“Cultivator and Country Gentleman.”

RHODODENDRONS AT KNAP HILL.

THESE are now in greater beauty than we ever remember to have seen them. Here may be found the original plant of Mrs. John Clutton, still the best white in cultivation, 15 ft. in height, and nearly as much in diameter, thickly studded with lovely trusses of bloom. Long rows of standard trees of albin elegans are also loaded with flowers, and the remarkably showy and distinct crimson-flowered kind, called Alarm, has perhaps never been seen in better condition than it is this year. The rosy-scarlet Brayanum still stands at the head of its class, and is equally attractive in a large or small state. H. H. Hunnewell appears to be one of the best of the crimson-flowered type, its well-formed trusses being shown off to advantage by the large, dark green foliage amid which they are set. Looking at what one sees at Knap Hill, improvements on existing kinds would seem to be impossible; this, however, is not the case, for seedlings—better than their parents—are continually turning up, and the work of hybridization, with the view of obtaining something new, is constantly going on. The chief aim is to produce good kinds that will flower late in spring, when all fear of danger from frost is over, for useful as early-blooming kinds are, their beauty is often greatly impaired by spring frosts. Amongst seedlings now to be found in Mr. Waterer's collection, one named Marchioness of Lansdowne is a charming addition to existing kinds; it bears compact, conical trusses of flowers, which at first sight remind one of these of the beautiful *Odentoglossum vexillarium*, except that they have faint, golden spots in the upper petals, and stout brownish-tipped anthers. Another very distinct seedling, as yet unnamed, bears flowers of a rosy-crimson colour, edged with white, the upper petals being conspicuously dotted with maroon. Others, of an equally attractive character, may also be found in large numbers. When we state that 150 acres of land are occupied by Rhododendrons, of all forms and varieties, some idea may be formed of the display which they now make at Knap Hill. They are also associated with masses of hardy Azaleas, which are most effective this year, having happily escaped the evil effects of frost. Amongst them are kinds bearing flowers of all shades, from pale yellow to the deepest orange-scarlet. We also noticed many seedling Azaleas, the flowers of

which are, as regards size, equal to those of the more recently introduced *A. mollis*. Amongst these seedlings, too, may be found kinds bearing deliciously-scented flowers, and of rich colours, and they have the merit of being perfectly hardy, and of blooming late in the season, when all danger from frost is over; moreover, unlike the older varieties, they flower when the plants are well clothed with leafage, a valuable recommendation. For those who are unable to visit Knap Hill and see the fields of American plants now in bloom there, a grand exhibition of them is provided by Mr. Waterer in Regent's Park, where a selection will be found of all the most attractive kinds. They are tastefully arranged on sloping banks, and covered by a large tent, but, owing to the faulty construction of the latter, the effect of the exhibition, as a whole, is greatly impaired.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

JUNE 19.

THIS, the largest show of the season, was in every way a satisfactory one, and the exhibits, which were numerous, were of an unusually attractive character. They occupied three spacious tents, which, together with the gardens (now greatly improved in appearance), were thronged during the afternoon with visitors. The Prince and Princess of Wales honoured the exhibition with their presence, and Her Royal Highness distributed the medals in the evening to the successful exhibitors. Mr. John Wills furnished the large circular tank in the centre of the walk approaching the exhibition tents from the Council-room with large square blocks of ice overcanopied by Palms and other graceful-foliaged plants issuing from a bed of Club Mosses and white Water Lilies.

First-class Certificates.—These were awarded to the following new and rare plants:—

Anthurium Veitchi (Veitch).—A noble-looking plant with large, glossy green and bronze, deeply-veined leaves upwards of 3 ft. in length. In every collection of fine-foliaged plants this should have a foremost place.

Anthurium Warocqueanum (Veitch).—A smooth, pointed-leaved kind, with white, conspicuous veins.

Pink, Tom Thumb Scarlet (Veitch).—A dwarf-habited variety bearing a profusion of intense scarlet semi-double blossoms: well adapted either for pot or border culture.

Pelargonium, Dr. Masters (Williams).—A free-habited variety with semi-double, maroon-scarlet blossoms, to which allusion has been made on previous occasions.

Thrinax gracillima (Williams).—A graceful-leaved Palm resembling a Cyperus, and admirably adapted for dinner-table or room decoration.

Croton, Prince of Wales (Williams).—A long, twisted, yellow and green-leaved kind with a compact but remarkably graceful habit.

Lilium elegans Alice Wilson (G. F. Wilson).—A distinct orange-yellow-flowered variety of the dahuricum type, likely to shortly find its way into all large collections.

Stove and Greenhouse Plants.—These, which were well represented, consisted chiefly of large miscellaneous groups. That shown by Messrs. Veitch & Sons was as remarkable for novelty as for skilful culture. It consisted of choice Orchids, amongst which was a fine mass of brilliantly-flowered *Masdevallias*, *Odontoglossum Alexandra*, *O. Roezli*, and a plant of the beautiful *O. navium*, bearing over thirty magnificent spikes of beautifully-spotted blossoms; a mass of *Begonia Acme* lighted up one side of this group, and red-leaved *Dracenas* gave colour to the other, and contrasted strikingly with the green-leaved Palms and gracefully-hanging Ferns which also graced this collection. The same firm also showed a large panful of the white and yellow-blossomed *Utricularia montana* in excellent flower; groups of insectivorous plants, placed on wooden stands and covered with bell-glasses; Pitcher-plants, always interesting on account of their singular forms; the graceful *Paulinia thabctrifolia*, seedling *Ixoras*, and *Todeas*, all of which, and many more, rendered this one of the most effective and deservedly appreciated groups of plants in the whole exhibition. Mr. William Bull contributed a collection of new and rare plants of a meritorious character; amongst them we noted a well-flowered example of the trailing *Bomarea Carderi*, finely-coloured plants of the curiously spotted-leaved *Dracena Goldieana* (represented in our last week's number), *Sadleria cyatheoides* (one of the most graceful of Ferns), numerous new *Crotoms*, neat baskets of *Odontoglossum vexillarium* edged with *Adiantum gracillimum*, and several new *Pelargoniums*. Mr. B. S. Williams showed an admirably arranged group of miscellaneous plants, amongst which were remarkably well-flowered specimens of *Odontoglossum vexillarium*, *Cypripedium niveum*, and a specimen of *C. barbatum superbum* bearing nearly fifty well-formed blossoms. The same collection also contained grand plants of *Dipladenia amœna* and *Allamanda grandiflora*, well-flowered *Azaleas* and *Statice* intermixed with Palms, Ferns, and fine-leaved *Crotoms*. Messrs. Osborn furnished, amongst other clean and healthy plants, good examples of *Pandanus Veitchi*, large specimens of the variegated New Zealand Flax in flower, well-grown Palms, and

Dracenas, set off to advantage through being associated with the brightly-coloured spathes of the Flamingo-plant (*Anthurium Scherzerianum*), the whole being edged with the graceful *Aralia Veitchi*, *Croton Weismanni*, and *Adiantum Farleyense*. Messrs. Jackson & Sons had a fine collection of plants, consisting of *Everlastings*, *Clerodendrons*, *Statice*, and a fine *Stag's-horn Fern*. These were backed up with large Tree Ferns, Palms, and *Dracenas*, and edged with small coloured-leaved *Dracenas*, *Crotoms*, and the pyramidal *Saxifrage* (*Saxifraga nepalensis*). Messrs. Charles Lee & Son, Hammersmith, had also a group of miscellaneous plants, amongst which were good examples of *Cordylina indivisa*, Australian Bird's-nest Ferns, *Cureuilgo recurvata variegata*, and a fine specimen of *Medinilla magnifica*, the latter bearing upwards of seventy pendent clusters of rosy-coloured blossoms. Messrs. John Standish & Co., Royal Nurseries, Ascot, contributed a group of *Carnations*, *Aralias*, *Dracenas*, and cut-leaved Japanese Maples; also plants of *Todea superba*, *Lomaria magellanica*, *Adiantum gracillimum*, and other Ferns. Messrs. Laing & Co. showed miscellaneous plants, consisting of Ferns, *Dracenas*, flowering *Crinum*s, *Caladium*s, and other well-grown plants. Messrs. Cutbush & Sons contributed stove and Greenhouse plants, all well-grown, and flowered Palms and Cycads. A capitially grown group of plants came from Mr. Thornber, gardener to Thomas Moss Shuttleworth, Esq., conspicuous amongst them were some very healthy specimens of *Cordylina indivisa*, and the crimson and green-spotted bronze-leaved *Croton undulatum*, and a remarkably fine specimen of *Cycas revoluta*. Messrs. Carter & Co. contributed a good collection of ornamental-foliaged plants, amongst which were good examples of the graceful *Cocos Weddelliana*, *Croton majesticum*, *Coleuses* of different kinds, and other plants, the whole being edged with well-flowered plants of *Ionopodium acule* in 6-in. pots, their lilac, starlike flowers being very effective. Mr. John Wills furnished a bank of fine-leaved plants, amongst which were Palms and Tree Ferns, while on a mound of Club Mosses were placed choice small-leaved *Caladium*s, cut flowers of Water Lilies, *Everlastings*, variegated Pines, and Pitcher-plants, the latter being placed on elevated pedestals. Mr. Wills also exhibited on this occasion his collection of choice seedling *Dracenas*, amongst which Mrs. Bausé was especially worthy of notice. Mr. John Hepper showed a rustic vase filled tastefully with *Crotoms*, *Cissus discolor*, variegated Pines, Ferns, and Grasses. Messrs. Hooper & Co., in addition to a collection of Ferns and Palms, furnished a miscellaneous group of plants, amongst which we noted many fine varieties of *Begonias*, especially the hardy *B. Froebeli*, in good condition. Messrs. J. & R. Thyne, Great Western Nurseries, Glasgow, had fine examples of *Croton Disraeli*, *Medinilla amabilis*, and a neat little plant of the brightly spotted-leaved *Bertolonia superbissima* under a hand-glass. Orchids were, for the most part, grouped with other plants. A good collection of them, however, was furnished by Mr. Heims, gardener to F. A. Philbrick, Esq., St. John's Wood; amongst these we noted well-flowered plants of *Epidendrum vitellinum* and *Oncidium macranthum*. Mr. W. Perry, Bristol, had also amongst others good plants of *Dendrobium thyrsoïdum*, *Odontoglossum Pescatorei*, and *Lœlia purpurata*.

Mr. Bull's Silver Cups, offered for 12 plants introduced by him since the commencement of 1874, were competed for by four exhibitors. The best groups came from Mr. B. S. Williams, and Mr. Wills, the former having excellent examples of *Dipladenia Brearleyana*, *Cycas media*, *Croton splendendum*, *C. majesticum*, and the useful *Aralia elegantissima*. Mr. Wills had a well-grown plant of the copper-coloured *Alocarpus Cannoni*, good specimens of *Lomaria Dalgairnsia*, and a fine plant of *Encephalartos Hildebrandi*. In the amateurs' class the best group came from Mr. H. Thornber, gardener to T. M. Shuttleworth, Esq., Preston, who had good examples of *Ixora regina*, *Sadleria cyatheoides*, and the best coloured specimen of the showy *Croton majesticum* which we have yet seen. Mr. C. Rann, gardener to J. Warren, Esq., Crawley, Sussex, had a pretty little plant of *Croton chrysophyllum*, the curly-leaved *C. spirale*, and a good specimen of the spiny *Martinezia granatensis*.

Market Plants.—The best collection of these came from Mr. Reeves, Acton; it was neatly arranged, and consisted, amongst other things, of finely-bloomed plants of *Lilium auratum*, blue and pink *Hydrangeas*, well-grown Palms, Ferns, *Mignonette*, and *Crotoms*. Messrs. Pounce & Sons, Westbourne Grove, had a very effective group, the back rows in which consisted of narrow green-leaved *Dracenas* and Mrs. Marshal Fuchsias placed alternately, in front of these was a row of *Everlastings* (*Rhodanthe Manglesii*), *Pelargoniums*, and *Heliotropes*, and a wide bank of *Agrostis pulchella* formed groundwork for a coloured motto. Mr. Herbst, Richmond, showed a group of Palms. Mr. E. Sawyer, Hyde Nursery, Edmonton, contributed *Hydrangeas*, *Calceolarias*, and *Pelargoniums*, edged with blue *Lobelia* and scarlet *Tropæolum*.

Cut Flowers, Bouquets, and Dinner-table Decorations.—These were all fairly well represented, the most attractive being the *Roses* shown by Mr. Charles Turner, who furnished twelve stands of blooms, amongst which we noted fine examples of *Miss Hassard*, *Devoniansis*, *Madame Charles Wood*, and the brilliant crimson-flowered *Lord Raglan*. From Mr. Hollingsworth, Turkey Court, Maidstone, also came several stands of *Roses*, amongst which were good blooms of *Niphetos*, *Prince Camille de Rohan*, and *Triomphe du Luxembourg*. Messrs. Barr & Sugden staged an extensive group of *Irises*, which embraced all the known varieties worthy of cultivation, not only of the German section, but also both Spanish and English *Irises*, including *I. Susiana*, *neglecta*, *Fairy Queen*, and a beautiful kind named *Porcelain Sceptre*. Mr. Parker, Tooting, also showed a unique collection of *Irises*, amongst which were many fine kinds. Messrs. Hooper furnished stands of *Pansies*, *Ranunculus*s, and *Pyrethrums*; and Mr. H. J. Elwes showed an interesting

group of bulbous plants, consisting of Lilies, Irises, Cyclobothras, *Cypripedium pubescens* and *C. spectabile*, and a remarkably fine example of *Orechis foliosa*. Mr. G. F. Wilson contributed cut blooms of Lilies, amongst which were fine flowers of *L. Krameri*, *L. Szovitzianum*, and *L. Washingtonianum*. Mr. Turner showed boxes of Picotees and Pinks in excellent condition, and Messrs. Barr & Sugden, Covent Garden, also exhibited good stands of flowers of hardy herbaceous plants. In the class devoted to dinner-table decorations there was a smart competition; the first prize was awarded to Messrs. Pounce & Sons, Westbourne Grove. The arrangements in this case were of a very simple but tasteful character, and the flowers used only such as may be found in any small garden. The decorations to which the second prize was awarded came from Miss W. Wood, Albert Gate, and consisted of Lilies, Heaths, Irises, Orchids, Isopleps, and light Ferns, tastefully arranged in three glass épergnes. A good arrangement was also furnished by Mr. W. Young, Camden Square. Messrs. Dick Radclyffe had a table filled with ornamental gilt épergnes and stands, but unfortunately too crowded to be seen to advantage. Bouquets were numerous; the best pair came from Miss Moyses, Belgravia, and consisted of Tuberoses, Eucharis, Jasmynes, Tea Roses, Phalanopsis, and scarlet Bouvardias. Mr. W. Stone, Centre Avenue, Covent Garden, showed a group of twenty-four bouquets, all of which were tastefully put together. One of the most admired floral arrangements came from Mrs. M. Hodgkins, Hyde Grove, Manchester, it consisted of silvery skeleton Fern fronds, leaves and flowers of various descriptions, the colour having been extracted by some method known to few except the exhibitor; they were arranged in wreaths, bouquets, &c., and placed on black velvet, and the effect was excellent. We were informed that such bouquets were much appreciated in winter, when real flowers are scarce.

Fruit and Vegetables.—The best collection of fruit came from Mr. Miles, gardener to Lord Carington, who had excellent green and scarlet-fleshed Melons, *Violette Hâtive* Peaches, remarkably well-finished bunches of Black Hamburgh and Foster's White Seedling Grapes, good Figs, Strawberries, and Cherries. Mr. Cox, Madresfield Court, and Mr. Goodacre, Elvaston Castle, also staged meritorious collections, consisting chiefly of well-grown Melons, Pine-apples, Grapes, and Peaches. The best Pine-apple came from Mr. Colman, Eastnor Castle, Leicestershire; it was of the Black Prince variety, well ripened, and large in size. Mr. W. Toomer, gardener to W. Knowles, Esq., staged excellent Queen Pine-apples each weighing upwards of 5 lb. Mr. Bates, Poulett Lodge, Twickenham, also had three Queen Pine-apples in good condition. From Mr. Akehurst, gardener to S. Copestake, Esq., Kentish Town, came some remarkable specimens of Black Grapes; they were not so large in the bunch as some which we have seen, but the berries individually were large and well coloured. The three largest bunches came from Mr. Edwards, Liphook, Hants, but they were deficient in colour. Mr. Farrance showed an excellent 15-lb. basket of Black Hamburgs. Well-finished examples of Muscat of Alexandria came from Mr. Edwards, and Foster's White Seedling in excellent condition was furnished by Mr. Bates, Twickenham, while Mr. J. Horwood, Farnborough, had fine bunches of Buckland Sweetwater. Nectarines were well shown by Mr. Colman, Mr. Horwood, and Mr. Hinds of Otterspool. The best Peaches came from Mr. Colman, who had the finest examples of the Abce variety we have seen this season; the same exhibitor also furnished half-a-dozen fruits of Victory of Bath Melon, and Mr. Hinds had a fruit of the old but seldom seen Conqueror of Europe Melon. Dishes of Sturmer Pippin and White Nonpareil Apples, good, considering the season, came from Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park. Strawberries of the Oscar variety were shown in good condition by Mr. Hinds; and Mr. Waters, gardener to Sir W. Bagge, had good fruits of British Queen. Of vegetables only three collections were shown. The first prize was awarded to Mr. Miles, Wycombe Abbey, who had fine Tomatoes, Broad and French Beans, and Onions. Mr. W. G. Pragnell, Sherborne Castle, Dorset, was a close second, with remarkably fine heads of Early London Cauliflower, Globe Artichokes, White Naples Onions, William the First Peas, and Telegraph Cucumbers. Mr. A. Harwood, Colechester, showed 120 heads of Asparagus, of very large size and excellent in quality; and Mr. Amys, Chadwell Heath, sent a well-grown brace of Improved Telegraph Cucumbers.

Miscellaneous Subjects.—From Messrs. Barr & Sugden came a group of Lilies of the Pyrenaicum and Bulbiferum sections, intermixed with a few plants of *Lilium auratum*. Mr. Richard Dean had a good group of herbaceous plants suitable for bedding purposes; and Mr. Roberts, gardener to W. Terry, Esq., showed a collection of old-fashioned border plants in good condition. Messrs. Barron and Sons, Elvaston Nurseries, exhibited new hardy Conifers of a meritorious character. Messrs. Ivery & Sons, Dorking, contributed a bank of hardy Ferns, consisting of all the best of cultivated kinds. Messrs. Veitch showed a group of dried Grasses and flowers tastefully arranged and much admired by all who saw them. Messrs. Hooper & Co., Covent Garden, also exhibited a large group of dried flowers and Grasses. The blue and white variety of *Campanula media* *Calycanthema* was shown in fine condition by Mr. Appleby, Boxhill Nursery, Dorking. From Mr. James, Isleworth, came a miscellaneous group of Pelargoniums; and Messrs. Charles Lee & Sons had their new *Cornus Mas aurea elegantissima* in good condition. Messrs. Dick Radclyffe & Co. contributed among other garden appliances miniature fountains, tastefully associated with Ferns; and Messrs. Lane & Sons, Berkhamsted, had an interesting collection of pyramidal Ivies. Messrs. Read & Co., Regent Circus, showed examples of garden syringes and pumps, amongst which we noted many improvements on the ordinary forms of construction. Messrs. W. Hatchman & Co., Wood Street,

London, showed examples of their patent garden tents and canopies, with netting, seats, &c.; the tents, which are made on improved principles, are light and elegant, and calculated to be largely used as summer-houses, &c., during the sunny months of the year.

Pelargonium Society's Exhibition.—This was in all respects excellent as far as the plants themselves were concerned, but, as regards numbers they were, perhaps, not so great as last year. In the class for six large Show Pelargoniums, Mr. Charles Turner, Slough, gained the first prize with brightly-flowered, healthy specimens of Prince of Prussia, Prince Leopold, Highland Lassie, and other equally attractive varieties; the next best came from Mr. Weir, gardener to Mrs. Hodgson, Hampstead, who furnished good plants of Lady of the Lake, Ariel, and Victory. In the class for four, Mr. Turner had well-managed plants of the brilliant-flowered Silvio and the white and purple Virgin Queen; and E. B. Foster, Esq., Clewer Manor, showed good examples of Despot, Artist, and a brilliantly-flowered kind named Illuminator. Amongst Fancies we noted fine examples of Lucy Turner and Princess Teck, from Mr. Weir; and good plants of the old Evening Star and the delicate Nelly Fordham from Mr. Turner. In the class of eighteen Show varieties, Mr. Turner exhibited well-flowered plants of Duchess of Edinburgh, Queen Victoria, and Digby Grand; and Messrs. J. & J. Hayes, Edmon-ton, had good examples of Prince of Wales, Triumphans, The Shah, and others. Large plants of the Zonal section were well represented by Mr. Catlin, gardener to Mrs. Lermite, Finchley; the most noteworthy amongst them, perhaps, were the salmon-coloured Mrs. Catlin, the brilliant Scarlet Corsair, and the soft crimson Hebe. The same exhibitor had also fine plants of the decorative or nosegay type, amongst which were brightly-flowered specimens of Mrs. Turner and Miss Saunders. Mr. Birse, gardener to J. H. Lermite, Esq., Finchley, had good plants of Pearson's Ethel, John Fellows, and Maud. Smaller plants were also shown in groups of eight, the best of which came from Mr. Catlin. Messrs. E. G. Henderson showed Queen of Stripes, a beautiful Carnation-flowered variety, dwarf in habit, and in all respects promising. Mr. Williams had a group of his new Show Pelargonium Dr. Masters', of which mention is made elsewhere. From Mr. Turner came an extensive miscellaneous group of Show and Fancy kinds, which were much admired, and which formed one of the most important features of the show. The best double white variety came from Mr. Burley, and was named Bridal Bouquet, an excellent kind for use in bouquets or floral decorations. The same exhibitor had also a miscellaneous collection of Pelargoniums, consisting of bronze, Zonal, silver-edged, and double-flowered varieties, all of which were remarkable in their way. Tricolors were well shown by Mr. W. Meadmore, The Nurseries, Romford. Mr. Turner had a group of double kinds in excellent condition, amongst which were good plants of Neomie, Asa Gray, and Illuminator. Cut blooms of Zonal Pelargoniums were well shown by Mr. Cannell, Swanley, Mr. Pearson, Chilwell and Mr. Burley, Brentford; the first named had good trusses of New Life and Lady Sheffield, and Mr. Burley had good specimens of Tom Bowling and Double varieties.

NOTES AND QUESTIONS—VARIOUS.

Establishing the Caper-plant.—Can any of your readers give me any suggestions as to the means of introducing Caper-plants into my garden. They grow wild outside my gate, but I have hitherto failed in all my efforts to induce them to take root on any of my walls.—*CARR, Naples.*

Wash for Rose Trees.—In reply to the enquiry made by "Marchal Niel" (see p. 612), I can recommend the following recipe, which I have used for years with unvarying success:— $\frac{1}{2}$ lb. of soft soap dissolved (not boiled) in soft water, 2 oz. of strong Sagu Tobacco, boiled slowly for about an hour, and 1 oz. of bitter Aloes, well mix with three gallons of warm water, and syringe or dip the shoots affected with blight or fly in it.—*WICKHAM.*

Rose Beetles.—I have sent you three beetles which have been, and still are making sad havoc with my Roses, especially standards. They lie concealed, in the daytime under leaves or any other covering, and about dusk commence their work of destruction. They not only destroy the young buds, but take off the bark. Those trees huddled rather late last year are completely ruined. R. J. T. [The two larger beetles (black) are *Otiorynchus fulvipes*; the smaller sandy-coloured one is *Otiorynchus notatus*, both gardeners' enemies. Hand-picking both of the perfect insect and grubs in the ground is the only thing that seems to get the better of them, and of course that can only be done on a very small scale.—A. M.]

Plantains on Lawns.—An amateur's lawn, more than an acre in extent, is covered with several kinds of Plantain too thick to eradicate by hand. Can any reader of THE GARDEN kindly suggest a remedy? Will lawn sand answer the purpose? and if so, will it destroy the small Clover, and at what time of the year is it best applied?—*BERRIS.*

Laburnums among Evergreens.—In shrubbery borders composed mainly of evergreens, Laburnums are highly effective when planted at certain intervals apart. Thus situated their golden tresses, backed up by the dark groundwork, are seen to advantage. The Laburnum being of a light feathery growth may be pruned to occupy but a small space.—*P. G.*

Curious Tree-planting Custom in Switzerland.—One of the many customs in Switzerland which leave a pleasing remembrance of a visit to that country, is that of planting trees on the occasion of a marriage or birth in a family. This is made an event of great importance among the better class of peasantry. All the members of each family meet at the house of the bride or the home of the bridegroom, and forming a procession, march to the spot, where after some complimentary speeches and expressions of good wishes, the tree is planted. This in those cantons where Vineyards flourish is usually a Vine.

"This is an art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE TREES ON THE THAMES EMBANKMENT.

A PARAGRAPH having appeared in the "City Press" containing misleading statements concerning the trees on the Thames Embankment, we think it only justice to those who are responsible for them to put the matter in a true light. The writer states, among other things, that the trees,

had they been judiciously managed, would have been by this time perfect pictures of beauty and symmetry, instead of the wretched, mutilated, arboreal skeletons they now appear, producing considerably less foliage than they had the second year after planting. Will any member of the Metropolitan Board inspect the Plane trees in Battersea Park, grown as they should be? Or if that be too far, will they inspect the lines of Planes planted in the Temple Gardens about the same time as those on the Embankment, but of little more than half their size or value, although now vigorous and healthy?

In the first place, the trees on the Thames Embankment are really in a very promising and healthy condition; they have been pruned, so as to open them well up, to prevent the wind from blowing their tops off, when young and not established. The second year after they were planted the heads of a good many of the young trees were blown clean off. By "opening" up their heads judiciously until they are strong in stem and root, the wind passes through without hurting them. No harm is done in any way to the health, form, or vigour of the tree; on the contrary, the practice helps it in all ways in a position more exposed to strong and sudden winds than in any park or garden. With reference to the trees in the Temple Gardens they differ mainly from those on the roadway by being mop-headed, from which they would probably suffer were they not better sheltered than their neighbours. They certainly promise to be beaten by those on the Embankment as regards form and vigour; of course a tree in a city garden has a much fairer chance than in a roadway, where gas and sewer pipes, flagstones, &c., surround it on all sides. With reference to the trees in Battersea Park to which allusion is made, these are the facts:—They were planted in 1863 or 1864, and they were pruned in precisely the same way as the trees on the Embankment until the year 1871; every year since they have been pruned to some slight extent. The trees on the Embankment now being in many cases well established, it is not intended to prune more than is necessary to preserve the natural form of the trees, where interfered with by the wind or accidents. We remember when they were first planted a well-known and experienced planter expressed his doubts as to their thriving, owing to the high winds, combined with the other adverse influences of the position. Seeing, notwithstanding, the excellent results already obtained, most people will admit that their condition is a matter for praise rather than condemnation. We can say, from a recent examination of the Paris trees, that those on the Embankment promise to equal the best of them at no distant day. If we had any remark to make to the authorities, it would be this—thin the trees themselves in good time as boldly as you have thinned the branches, and you will some day have a nobler avenue of trees than any in Paris, where tree planting in the streets was begun on an enormous scale many years before it was in London.

WOOD PRESERVATIVES.

ACCORDING to observations made on a railroad in Germany, the proportion of renewals was, with Oak sleepers (not treated) after twelve years of service, 74.48 per cent.; with Oak sleepers treated with chloride of zinc, after seven years, 3.29 per cent.; with Oak sleepers impregnated with creosote oil, after six years, 0.09 per cent.; with Pine sleepers impregnated with chloride of zinc, after seven years of service, 4.46 per cent. The practice of this railroad since the year 1870 has been to employ only Oak for sleepers, which are impregnated either with chloride of zinc or with creosote oil. My own observations confirm these facts after nearly seven years experience in creosoting gates and fencing materials. The

first fence put up with creosoted wood was in September, 1870; it was a three-rail, split Oak fence (partly sapwood) enclosing a new plantation. As this was our first experiment, I put in a few lengths of split Oak and sawn Larch posts, rails, and stakes uncreosoted. I inspected this fence recently, and the result is that the creosoted portion is as sound as possible; the posts are quite firm in the ground, and not a particle of fungus or Lichen is to be seen on it; indeed, it is as clean as it was on the day on which it was fixed; whereas, the uncreosoted portion exhibits a striking contrast, the posts near and under the surface being covered with fungus, and already loose in the ground through decay, while the upper portions of the posts, the rails, and stakes are covered with Lichen and Moss. I find that wherever creosote is present, none of these vegetable growths can exist. When this fence was erected, I was doubtful whether sappy Oak could be rendered more durable by means of creosoting; I am, however, now thoroughly convinced that when creosoted it will resist decay for many years. There is one important matter that is necessary, and that is, the timber should be thoroughly dry and seasoned before being immersed in the pickling tank; indeed it should be split or sawn and stacked for several months previous to being subjected to the creosoting process. I am trying other experiments with various sorts of creosoted timber for fencing. Scotch Fir was at one time considered useless for sleepers, but it is now used extensively for that purpose in a creosoted state on the South-Western Railway. We have sold many thousands of Scotch Fir trees to contractors for sleepers, and at present we are in treaty respecting another large supply for that purpose. Larch, Spruce, and other thinnings of plantations, if barked and seasoned, and afterwards creosoted, are rendered very durable for rails, stakes, and hop-poles. Thus treated they will probably last double the number of years that they would do if they were not creosoted.

G. B.

SPRING GARDENING AT CASTLE ASHBY.

SPRING flower gardening has been a great feature here for some years, and a long-continued practice and study of the habits and flowering time of spring flowers has enabled me to select such as are most suitable for a display commencing in ordinary seasons about the second week in April and continuing on until the second or third week in June, when they have to give place to plants for summer bedding, which, however well done, is only second to the spring display. Every one should therefore take a lesson from Nature in this matter, and supply the vacancy which occurs so generally in garden decoration during March, April, May, and June with spring flowers, selecting from the many and great varieties of beautiful and almost entirely neglected plants, such as will afford a display through the early spring months onwards. The sorts of plants used are not of the least importance if they furnish the proper colour and yield flowers at the required time; they should also possess suitable habit and plenty of bloom, both of which are to be found amongst the attractive varieties which we now have at command, British as well as exotic. Although we have a display more natural and even more beautiful than in summer, and although of some kinds it requires a much greater number, they can be produced without the expense of house or fuel; consequently this system of flower gardening will doubtless become much more popular than at the present time with all lovers of natural-home floral beauty; and in addition to this kind of spring flower gardening, the more natural semi-wild and woodland walks and waysides may also be much improved in appearance. Now that the bloom of early spring flowers is at an end, a word about their future welfare may not be out of place. We must, in order to insure a good and satisfactory result next spring, attend to their little wants by seeing that nothing suffers through drought, or that the plants do not become choked by long Grass or weeds being allowed to grow amongst the clumps of Primroses and their hybrids of many colours, Polyanthus, Daisies, &c. They receive more injury by the non-observance of this than from any other cause. We are too much inclined to think because they are wild or semi-wild that they will care for themselves and supply their own wants at this season of the year, but this is

a mistake. It is also needful to see to the many small seedlings which appeared early in spring spontaneously round about the clumps of old plants, and which will now have grown large enough to be seen amongst the Grass; it will greatly improve the growth, if time can be spared to pick out the Grass by hand or cut it away by a small pair of shears; they will flower abundantly in spring if carefully attended to, and will bloom better and appear more natural than plants introduced from the seed or nursery beds. The same rule applies to all kinds of plants used in a semi-wild state. On my first establishing a semi-wild garden, and paying a little attention to the woodland walks here, I resorted to the formation of stone beds cropping up out of the earth a little above the surface in large spaces—not little dots; these beds of stone are now covered with Ivy of different kinds, Vincas, Aubrietias, Hypericum, Alyssums, &c.; various kinds of bulbs are planted about them, and grow up amongst the green plants. These raised clumps serve to undulate the surface, and produce a charming effect when clothed with Primroses of all colours, Polyanthuses, Myosotis, Violets, Cerasiums, and many other kinds of early flowers, all of which spring up spontaneously round about the clumps, and require little or no attention except clearing the Grass from around them. In order to give foliage effect Cardoons, Globe Artichokes, Common Rhubarb, Heracleums, some of the strong-growing Herbs, such as Balm, Tansy, Mallows, Golden Thyme, Polygonum, Phytolacca, Hyoseyamus, Helleborus, tall-growing kinds of Campanulas, Wallflowers, Double Furze, Lunaria, Japanese Pyrethrum (single and double), are introduced. To these are also added numerous other plants, all grown in clumps in a semi-wild state on ground occupying a long range of bank, which slope down to a lake below. In the bank near the water's edge I have here and there blocks of stone; these are covered with Aubrietias, Daisies, Viola cornuta, and numerous others; German Irises are also planted in great clumps and do well. I have likewise introduced a great variety of Willows for effect. It is necessary to annually cut them down to the ground in order to produce the various colours in the young wood. I have here enumerated only a few of the many introductions to my bank of spring flowers, which are now fast fading and going down to rest, only, I hope, to appear again with increased beauty and freshness in the forthcoming spring.

G. B.

MR. GERARD NOEL ON RICHMOND PARK.

In reply to a question by Sir G. Campbell, in the House of Commons the other night, Mr. Noel said:—With regard to opening footpaths in the copses at Richmond Park, I fear that would be impossible. They are planted to beautify the Park and to replace trees which in the course of time perish. If paths were cut through the plantations, great expense would be incurred from the amount of fencing which would be required to keep out the deer, and after the lessons on economy I have this year experienced from hon. gentlemen opposite, I hardly like to embark in fresh expenditure on the parks. [We are glad that it is so, because Richmond Park is more beautiful by far than it is likely to be if walks be made through the copses, &c. Richmond Park is the finest in its way in the environs of London; it would be the greatest mistake ever made to run walks through it, "like those in the Bois de Boulogne." If for no other reason than as a charming contrast to the other London parks, it ought to be kept mainly as it is. If landscape gardening generally meant developing the natural beauty of a place, we might offer other advice, but till we have a school of landscape gardeners who justify their name, we trust Mr. Noel's view will be followed.]

Calceolarias at Clapham.—Quite an exhibition of Calceolarias belonging to the herbaceous class may now be found in the gardens of Mr. Hudson at Clapham. They are chiefly in 6-in. pots, planted in light, fibrous loam; they are kept clear of insects during the growing season by means of frequent fumigations and abundance of air and water, and they are now furnished with large, healthy leaves, which completely hide the pots, and as regards the flowers they are produced in heavy masses on stalks not more than 10 in. or

12 in. in height. About 150 such plants as these may be seen arranged here on the stage of a greenhouse, where their well-shaped and variously-coloured flowers associated with those of other plants have a charming effect.—C.

HOSE-IN-HOSE POLYANTHUSES.

SURELY Mr. Wooler (see p. 527) cannot be the originator of the golden Hose-in-hose Polyanthus. The particular Hose-in-hose of which I previously made a note was a seedling from Golden Gem, a variety to which a certificate was recently awarded at South Kensington. It was raised in Dorsetshire by an admirer of these old-fashioned flowers, who has long made them subjects of special care. That Mr. Wooler may have raised yellow Hose-in-hose Polyanthuses, I do not dispute, but he certainly was not the originator of the one in question. It should be known that the extreme south-west of England has long been rich as regards these curious and varied forms of Polyanthus, but it is only now and then by chance that they make their appearance in commerce. A golden-yellow Hose-in-hose came here from Ireland, where it originated, and others from other sources. All the fine duplex varieties came to us originally from Germany, and as regards the late Mr. Donald Beaton's statement that the Hose-in-hose does not reproduce itself from seed, I can assert that these fine duplex forms do so freely. A very fine pure white and an equally good orange Hose-in-hose has originated out of these, and flowered for the first time this year. I differ from Mr. Wooler in his estimate of the value of double Polyanthuses; as far as I have seen doubles, I find them to be only single flowers spoilt. Let lovers of the curious and abnormal say what they may, a good head of bloom, whether on one of our charming single Primroses or rich Polyanthuses, is greatly to be preferred to that of the best doubles. The features of a good single flower in either of these are the elevated and refined thrum eye, the beautiful, clear, golden or lemon centre, and the dense, rich, well-defined outside ground-colour. To attempt to force up petals into the eyes of these gems would be a species of floral sacrilege, spoiling one of the gems of earth to produce a monstrosity. After all that has been written regarding them, how much less beautiful are the semi-double and double Chinese Primulas than the single varieties; and what double ordinary Primrose can excel a single form, in addition to which we get not only much less flower, but plants with weakened constitutions? In the open ground where, during the year, the rich purples, violets, crimsons, reds, and other choice single kinds will thrive luxuriantly, the dark-coloured doubles would die. It is only the common sulphur, white, and lilac sorts that are thoroughly hardy. Whether these doubles originated from seed or as sports is one of those things that are buried in oblivion; but I rather incline to the latter idea. If they had come from seed, it is probable that we should yet be producing new kinds; but in all my experience of single Primroses I have seen nothing likely to lead up to a double flower. A few years ago I found in a market garden a plant of the Lilac Primrose that had reverted to a single form. I kept it for a few years and propagated it, and it flowered freely, but the flowers were either devoid of style, or had it imperfectly developed, therefore did not produce seed; through lack of vigour it has since died.

A. D.

The Abele Poplar.—Mr. Berry's notice of this tree (see p. 513) reminds me of one peculiarity belonging to it not generally known, and that is that it is the very best of all trees for sea-side planting. On the west coast of Lancashire, in and about Southport, where there is scarcely an ounce of soil in the whole parish, and where the west wind seems always blowing, this tree thrives to perfection; when used, however, as a nurse plant, owing to its having in a young state a kind of sprawling habit, it requires well looking to, or it would soon monopolise the whole wood, growing into a tree before other kinds have fairly taken hold. Whatever may be its merits as an ornamental tree, it is likely to be eclipsed by the far handsomer *Populus argentea*, or Silver Poplar, a tree with a more upright habit, and quite as quick in growth as the former, with the under sides of the leaves densely silvery or tomentose.—THOMAS WILLIAMS, *Ormskirk*.

Pelargonium Cooperi.—This pretty little *Pelargonium* is perhaps not so well known as it ought to be; the flowers are of no importance, but the leaves are very beautiful, about the size of a shilling, and intensely green, with a heavy black horseshoe or zone. Its habit being diffuse or trailing, it makes a neat pillar plant, or for training over the handles of rustic baskets. Trained on a wire, too, as an edging to beds of *Pelargoniums*, I fancy it would have a beautiful effect; it is a rapid grower, and is easily raised from seed.—THOMAS WILLIAMS, *Ormskirk*.

NOTES OF THE WEEK.

ERINUS ALPINUS ON ROMAN RUINS IN NORTHUMBERLAND.—On Tuesday last I took some friends to see the excavations in Chesters Park of the ancient Silurian station on the Roman wall. The walls of the houses stand from 3 ft. to 6 ft. high; we found the joints in the masonry filled with thousands of fine showy plants of *Erinus alpinus* in full bloom, chiefly in those parts of the ruins where cement has been used, as in the bath-rooms, tepidarium, &c. The plants first made their appearance a few years ago soon after the buildings were uncovered. Their origin has been the subject of not a little speculation, of which there has been an abundance lately in trying to account for the treasure discovered last autumn at the adjoining station of Procolitia, consisting of some 30,000 Roman coins.—W. A. T., *Hesham*.

LOBELIA THE BRIDE.—This is the name given to a new white-flowered *Lobelia*, which has during the past few weeks made its appearance in Covent Garden Market. The plants are grown in 5-in. pots, and the flowers, which are larger than those of the common *L. speciosa*, are of a pure white colour, and are produced in abundance. The habit of the plant appears to be such as to render it a very desirable kind either for pot or border culture, and it is indeed in every way the best white-flowered *Lobelia* we have yet seen.

LILIUM GIGANTEUM AT HOLYROOKE, CO. WICKLOW.—There are just now in flower in the conservatory here what appears to the writer to be two unusually fine pot specimens of this stately Lily. The height of the stems, as taken on Saturday, 23rd inst., was 12 ft. 9 in., each carrying thirteen noble blooms fully expanded. The stems are stout in proportion to the height, and straight as a gun-barrel. The bulbs were only planted in March last. The soil used in potting was sound and rich, and they are at present in 14-in. pots.—B.

LARGE PITCHERS OF NEPENTHES SANGUINEA.—Messrs. Backhouse have recently had a specimen of this somewhat rare Malayan Pitcher-plant, one of the pitchers of which, including the lid, measured close upon 14 in. in length and 9 in. in circumference; the lid was about 3½ in., leaving nearly 10½ in. for the pitcher itself. Has this size ever been exceeded? Two or three plants of *Nepenthes villosa*, from Borneo, are also bearing very fine fringed pitchers.—P.

RHODODENDRONS AT THE BAOSHOT NURSERIES.—We do not recollect ever seeing *Rhododendrons* blooming so finely as they are doing this year, and a ramble through Mr. Waterer's grounds just now is most enjoyable. Their most conspicuous feature is the great number of handsomely-grown standards everywhere to be met with heads varying in size from 6 ft. to 30 ft. in circumference, and completely laden with bloom. The planting, too, has been so arranged that at every step fresh varieties may be seen, and when standing on the higher parts of the ground, and overlooking the whole, the effect is charming. Of new kinds there is this year no scarcity, and some amongst them are different from any hitherto seen in cultivation. The fine exhibition of *Rhododendrons* now on view at Hurlingham House, Fulham, consists of selections from these grounds. On the day on which it was opened it was visited by the Prince and Princess of Wales and the Princess Louise, in compliment to whom one of Mr. Waterer's best seedlings was named, by permission, *Rhododendron Princess Louise*.

FRUITS AND VEGETABLES IN COVENT GARDEN.—The supply of both fruits and vegetables to this market is now abundant. In the Centre Avenue may be seen large banks of first-class Peaches of *Grosse Mignonne* and other kinds, and huge baskets filled with most excellent Grapes. On one of the stalls we particularly noticed remarkably fine examples of *Muscad* of Alexandria, large both in bunch and berry, and the colour and finish such as could not fail to please the most accomplished Grape-grower. *Madrasfield* Court, too, may be seen in unusually good condition, clearly showing that it is a Grape which may be forced with advantage. Cherries, both black and white, are very abundant, and fast falling in price. Green Plums from Algiers continue to arrive, and their quality is improving. Apricots from Spain are more abundant than they have hitherto been, and they are, moreover, of better quality. In foreign Pine-apples there appears to be a falling off as regards the supply, and consequently English-grown fruits, though fairly abundant, are very high priced.

A NEW LONDON PUBLIC GARDEN.—It is satisfactory to find that, notwithstanding the great demand for ground for building purposes in London, open spaces are still being set apart for gardens. One of these, the burial-ground attached to St. Pancras Church (one of the oldest edifices of the kind in London), was opened to the public on Thursday last. Some time since it was wisely determined by the Board of Works to convert this disused graveyard into a public

garden, instead of allowing it to fall into the hands of railway companies or builders. The work, which has now been completed, consisted of removing monuments, gravestones, and other obstructions, making wide walks, and planting such trees as are best calculated to withstand a smoky atmosphere. As regards the garden proper, we regret to find the usual formal flower-beds (which will, of course, be bare throughout the winter months, through being planted with tender plants) monopolizing a great part of the space. In a few places here and there, however, some attempts have apparently been made to produce more natural effects.

LIGUSTRUM VILLOSUM.—This is a very beautiful kind of Privet now in flower, with long and drooping branchlets covered with pretty wreaths of white flowers and gratefully scented.

CANTUA DEPENDENS BLOOMING OUT-OF-DOORS.—Mr. J. Luscombe informs us that this handsome old greenhouse plant, seldom seen in bloom, is now in flower out-of-doors in his garden at Coombe Royal, in Devon. It is about 10 ft. high, and grows against a south-east wall.

THE COLORADO BEETLE IN GERMANY.—The Colorado beetle, in every stage of development, was discovered the other day, according to the "Daily News," in a potato field in the vicinity of Cologne. The field belongs to a butcher who had purchased some American bacon. The fact was immediately notified to the Ministry of Agriculture.

CYRTANTHUS MACOWANI.—This is again in flower with me, and its clusters of scarlet bells, set off to advantage by the dark green, smooth foliage, are very attractive. It is easily cultivated, and flowers readily in pots. In winter I keep it somewhat dry.—MAX LEICHTLIN, *Baden Baden*.

FLORAL DECORATIONS AT REGENT'S PARK.—The Royal Botanic Society deserves great praise for the spirited manner in which it encourages this branch of art; not only does it devote one of its greatest "field days" every year exclusively to this object, but it also offers prizes for it to the value of upwards of £120. If there be not a fine display of decorations on Wednesday next, it will not be attributable to want of variety in the objects for which the prizes are to be competed; since, besides the usual liberal offers for dinner tables, bouquets, &c., we find prizes offered for plants arranged in standing and in hanging baskets, and for the decoration of a balcony garden, and of a recess or fire-place in a room. We also find prizes offered for cut flowers arranged in a hanging basket, for a pillar or column, as a festoon, and as a wreath for the wall of a ball-room, as a head-dress, and in a device of any kind suitable for personal adornment. Last, not least, there are prizes offered for flowers which "only expand at night." And further, for fear this comprehensive list should not include everything, the judges are to be requested to award special prizes to any novel adaptation of natural plants, flowers, or leaves to decorative purposes, which they may consider worthy of notice. Our columns have contained, from the first so many original communications and illustrations respecting floral arrangements and decorations of all kinds, that we look forward with much interest to the display at the evening fête in Regent's Park on the 4th of July.—V.

ANNUALS GROWN IN POTS.—An interesting collection of these, consisting of about 20,000 pots, is now being exhibited by Messrs. Carter & Co., of High Holborn, in the gardens of the Royal Botanic Society, Regent's Park. No class of plants is more neglected by amateur floriculturists than hardy annuals, a circumstance probably arising from a general absence of knowledge as to their wants and beauty, and yet there is no other section of the plant world that more generously repays the cultivator for the very moderate care and attention involved in bringing them to perfection. Whether as decorative plants for the conservatory, or as flowering plants for the dwelling-house window, annuals are equally valuable, and the simplicity of their cultivation in pots is abundantly demonstrated by the exhibition in question, whilst the brilliant yet soft shades of colour, almost infinite in variety, combined with the delicate perfume that is emitted by many of the species, are singularly striking. To the general run of horticultural shows this exhibition indeed furnishes a pleasing contrast, and we believe the display to be quite novel in character. Many kinds of annuals would, if well grown, form objects as beautiful and showy as any plants seen at ordinary flower shows—*Rhodanthe Manglesi*, for example, yet how often do we see this a poor thin plant from being allowed to flower soon after being sown! What beautiful specimens, for instance, could be made of some annual Lupines, Sweet Peas, *Lobelia speciosa*, Larkspurs, Stocks, and various ornamental Grasses! Messrs. Carter have done well in producing such an extensive exhibition, and we trust that they will continue it every year until the public shall have learned more than they now know about hardy annuals.

FLORAL DECORATIONS AT THE CRYSTAL PALACE.

At the Rose Show held at the Palace on the 23rd inst., the classes for table decorations, bouquets, &c., proved as usual most attractive, though I saw nothing novel either in the way of stands or arrangement; the exhibits, taken as a whole, were pretty even and equal to those of former years, though I remarked many names missing of those who have been wont to exhibit yearly at Sydenham. In class A (open to all) the first prize was awarded to Mr. Chard, gardener to Sir F. Bathurst, Clarendon Park, Salisbury. This arrangement consisted of a Cocos in the centre of the table, round the base of which were grouped blooms of Pelargoniums, Spiræas, Stephanotis, Orchids, and Begonias, with the addition of Ferns and Grasses; also up the Cocos stem was twined a spray of *Lygodium scandens*. At the top and bottom of the table were March vases, with trumpets set in the upper tazzas. These stands were decorated with flowers similar to those employed around the centre-piece, with the addition of large, heavy spikes of a dark blue Larkspur rising out of the trumpets, one in each. The spikes of this flower did not match, and indeed its use was a sad mistake, as it quite spoiled an otherwise pretty arrangement; between the centre-piece and the stand at each end stood a large-sized specimen-glass filled with Corn-flowers, Orchids, Grasses, Ferns, &c.; outside of these were four more specimen-glasses decorated in a similar manner to those before described, and round the table were twelve small specimen-glasses, each containing a button-hole bouquet. In this class the second prize was awarded to Mrs. Burley, Brentwood; and the third to Mrs. Seal, Sevenoaks, who's table was generally admitted to be much lighter and prettier than that which gained the first prize. Mrs. Seal made a charming effect with little baskets of white Rose-buds and foliage. The first prize in Class B (amateurs) went to Mr. Sperling, South Norwood; it was like that to which the first prize was awarded in Class A. The centre-piece of this table consisted of a Cocos round the base of which were blooms of blue Larkspur and white Water Lilies, with the addition of trails of Japan Honeysuckle and fronds of *Adiantum Farleyense*. At each end were March vases, arranged to match and form a pair; in the lower tazzas were blooms of crimson Cactus, white Water Lilies, and Stephanotis, with fronds of Ferns lightly interspersed amongst them; in the second tier were trusses of Stephanotis and scarlet Bouvardia, with fronds of Maiden-hair Fern; the trumpets were filled with light plumes, consisting of Grasses, white Rhodanthe Manglesi, and pips of scarlet Bouvardia wired. Round the centre-piece were grouped four glass baskets, filled with Rose blooms, trusses of Pelargonium, and sprays of Selaginella; the effect of these baskets was spoiled by the flowers selected being too heavy; round the table were placed ten specimen glasses, each containing a small arrangement. Mrs. Seal was awarded the second prize in this class, and Mr. Soder the third. The first prize in Class C (ladies only) went to Mrs. Soder for a pretty table, the effect of which was spoiled by the glass baskets employed in its decoration being only half filled. In this class Mrs. Seal again took the second prize, and Mrs. Burley third. There were other classes as well as those I have enumerated for small decorations, such as single stands, hand and button-hole bouquets, &c. I stated in THE GARDEN lately that the Rose was one of the most difficult flowers to arrange satisfactorily, and this I think was well illustrated by those staged at this exhibition. Why were the table decorations not advertised this year? Formerly large posters announced "The great Rose show and exhibition of table decorations," but this year table decorations were not mentioned. It was well, however, that these classes were not forgotten in the schedule, or the exhibition would have proved a poor one. On account of the lateness of the season many vacant places were visible.

ANNIE HASSARD.

HERBACEOUS AND ALPINE PLANTS IN SCOTLAND.

ONE of the best collections of these which I have seen in Scotland is that of Mr. Robertson Munro, Abercorn Nursery, Piershill, Edinburgh, and should any one be in that district they will be well paid for their trouble should they visit this place. The following were most noticeable when I visited the nursery last week; being perfectly hardy it is a great pity that they are not more generally cultivated, for in a good collection something is always to be found in flower. I will begin with *Anthericum Liliastrum* (St. Bruno's Lily), the largest of this exceedingly interesting genus; of this plant a coloured figure was given in THE GARDEN (see Vol. IX, p. 12). Of *Aquilegias* I saw ten distinct species, amongst which the most beautiful perhaps was *A. glandulosa*; the interior base of its flowers is white, with pale blue petals; the spurs are short, and the flowers measure 2½ in. across: it is a native of Siberia. *A. chrysantha*, with its large yellow flowers, must also be very

showy. *A. Skinneri* is the best of the scarlet section: of this Mr. Munro possesses a white form. *Anemone sylvestris*, with its large white flowers, is very showy and attractive. The North American *A. dichotoma* was just coming into flower. *Sisyrinchium odoratissimum*, a rare plant, was in flower. Amongst the smaller-growing plants I noticed the *Edelweiss* (*Gnaphalium Leontopodium*); no difficulty is found here in growing this, one of the most interesting of Alpine plants; it seeds freely, and young seedlings were making their appearance round the old plants in abundance. *Hutchinsia alpina*, a plant not more than 2 in. high, was smothered with lovely pure white flowers. The Pyrenean *Arenaria purpurascens*, with its tufts of rosy-purple flowers, was also very attractive. Here also are grown a large variety of *Saxifragas*: *S. Burseriana* was just past; *S. hibernica* was very fine; *Silenes* also formed a very interesting class; *S. maritima* fl.-pl., with double white flowers, is worthy the attention of lovers of this beautiful family, the flowers are large, and pure white. Mr. Munro has also a very fine collection of *Primulas* consisting of upwards of thirty distinct species; he finds them succeed best in a northern aspect. They are all growing luxuriantly, and are pictures of health. I was sorry I was too late to see them in flower, but the following were still in good condition, viz., *P. scotica*, *P. farinosa*, and *P. abyssinica*, the last, with fine heads of golden-yellow flowers, being very attractive. *P. Parryi*, a kind with large rose-coloured flowers, and *P. sikkimensis*, pale sulphur-coloured and somewhat rare, were here quite at home, and flowering most luxuriantly. *P. Munroi*, a sort with pure white flowers and slender stems about 8 in. high, was also very fine. In a pit plunged in ashes, growing most luxuriantly, are about 4000 Alpine plants in fine condition. Mr. Munro informed me that he attributed his success to giving them a position where they get plenty of sun; in the summer months they are frequently watered during the daytime, and when I mention that such kinds as *Androsace*, *Soldanella*, and the scarcer kinds of *Dianthus* are flourishing well, it is at once apparent that this system is well adapted for the cultivation of this beautiful family of plants. Mr. Munro is a skilful hybridizer, and annually raises many seedlings; therefore, any one visiting his nursery is almost sure to find something interesting.

A. O.

Chamærops excelsa in Cornwall.—In THE GARDEN (see p. 515) I observe that Mr. Hovell, the gardener at Heligan, asks whether there is any better specimen of this Palm in the open air than the one at Heligan, which is 8 ft. in height, and was planted about twenty years ago; allow me to say that I have one, planted in 1852, and it is now much more than 8 ft. in height. The plant at Heligan I believe to be a male; mine is a female, and fruited after being fertilized by the plant at Heligan some eight or ten years ago. I have a male plant now in blossom, about 12 ft. high, and hope to fruit my large *Chamærops* this season again.—J. T. BOSCAWEN, *Lanmorran Rectory, Probosc.*

Littonia modesta.—This as commonly seen in plant collections is not a striking plant, but when well grown it is very beautiful, especially on rockwork. In April I put several good roots of it in a perforated pot, using a light sandy soil. I keep them in the greenhouse till all danger from frost is over, and then I plunge the pots in a warm corner of my rock garden; there they grow rapidly, and the roots escaping through the holes in the pots, strengthen the plants. They do not produce one or two small flowers, but many large and substantial ones in whorls one above the other. In autumn when the stems turn yellow, I take the pots into the greenhouse again, and keep their contents dry.—MAX LEICHLIN, *Baden Baden.*

Green Fly on Roses.—The following is a simple, quick, and effectual method of clearing Roses of this pest:—Pour water slowly from a watering pot with a fine or medium rose over the leaves infested, holding them very slightly with the left hand, gently moving the fingers all the time; the insects will wash off easily the moment they feel the touch, and cleaner than if the plants were syringed for a length of time they cannot bear the slightest contact with the fingers and water without going. If you shake the shoots occasionally during the water falling upon them, it will also help to clear them of the drowned flies. No wash is needed by the above method.—W. A. T., *Herkum.*

Louis Philippe Cherry.—As the Cherry season is near at hand, will those who love and have Cherries examine the *Louis Philippe*, and report on its merits? I imported the variety from Leroy in 1848, and at first did not value it as it deserves. I know it now, and in many respects it has no equal.—"Country Gentleman."

Echeverias in Flower.—These when seen in full flower in quantity, are very handsome, affording quite a new tint of a pleasing colour, viz., bright orange-red. I have here two borders, each over 200 ft. in length, containing four rows of *Echeveria secunda* glauca planted thickly in front, and they are the admiration of all who see them. Many of the spikes branch, making the bloom very abundant.—W. C.

MOOR PARK.

THIS, Lord Ebury's seat in Hertfordshire, and a place of considerable historical interest, is situated in a lovely valley, through which a fine view of the distant country in the direction of Watford can be obtained from the garden front. The park itself, 500 acres in extent, and well known as a place of public resort on all holiday occasions, is beautifully undulated, and contains some fine trees, chiefly Oaks. Two of these, protected and called "an aged couple," though now dead or nearly so, and covered with Ivy, must have been full-grown trees at the time of the "Wars of the Roses," with which it is said the history of Moor Park began. One of them, the largest, measures 28 ft. round the trunk. Near one of the entrances to Moor Park is a fine old tree still standing in stately grandeur, though now hollow with age, and mutilated by the fury of many tempests, which is called Wolsey's Oak, or the Cardinal's Oak, either because Wolsey planted it or sat under its once spreading branches. Of Cedars of Lebanon, too, there are some remark-

crop out of the ground here and there like Cypress "knees." Some of the branches, too, lying on the ground have layered themselves into it, and become well-rooted, independent trees. Here, close to the water's edge, are huge masses of Rhododendrons still in bloom, deciduous Cypresses, easily distinguished even at a distance by their peculiar shade of green, Giant Thujas, specimens of *Araucaria imbricata* at least 40 ft. in height, grand examples of Larch, Weymouth Pine, Common Spruce, *Taxodium sempervirens*, *Pinus Pinsapo*, *Cryptomerias*, and *Wellingtonias*, all occupying ground so elevated that from underneath the shade of their boughs the surrounding country can be seen for miles. The kitchen garden lies on the other side of the park; it contains long ranges of glass structure all well stocked with Vines, Peaches, and Pines bearing good crops, and heated by means of one of Cowan's lime-kilns. It warms some 5000 ft. of piping, but at considerable cost, owing to there being little sale for the lime, and from the labour expended in obtaining the chalk, which is burned along with

Moor Park.

ably fine examples, one of which, standing close to the mansion and of great height, has a trunk 26 ft. in circumference at 3 ft. from the ground, and there are others equally large. The accompanying woodcut shows the Italian garden, with its dwarf wall, which cuts it off from the park, its sentinel-like Irish Yews, Thujas, and Junipers, and its vases, statuary, and other appendages, belonging to a strictly geometrical garden, the only blemish, as we think, on the face of this lovely park. Much prettier are its surroundings, in which is a well-kept tennis lawn with a Sweet Brier hedge on two sides, and on a third Scarlet Thorns still loaded with blossoms. Beyond is what may be termed an arboretum, consisting of coniferous and deciduous trees, some of them unusually fine specimens. The prettiest spot, however, about Moor Park is what is called the old pleasure ground, a circular enclosure, in the centre of which is a small piece of water, and on the rising ground above it a temple, overhung by some of the oldest and finest trees on the estate. Some of these rise to a great height, their aged limbs being chained together to keep them from being damaged by the wind; their roots spread far and wide, and

Welsh culm and coke. It also contains several plant houses and pits; of the latter, one is wholly devoted to Gardenias, from which 1000 blooms have been cut since February. To fruit trees and vegetables some 8 or 9 acres are devoted, and nothing could be in better condition than the latter; but of the former, with the exception of Cherries, Currants, and Gooseberries, there is here, as elsewhere, but a poor crop. The famous Moor Park Apricot, as is well known, once flourished here. The parent tree, which was brought from the East by Lord Anson somewhere about 1754, lived on till towards the end of 1840, when it died.

Grevillea robusta from Seed.—The elegant Fern-like foliage of this *Grevillea* gives it an effective appearance in all descriptions of decoration, either for planting out during summer, or for the conservatory, drawing-room, or dinner table. It is very easily raised from seeds sown in heat, but they should be new, as failures may and do arise from sowing old seeds. Young plants a year old or so are very useful for the purposes just named. I have a number of young plants in 4½-in. pots sown last autumn. A mixture of sandy loam and peat suits them well: two-thirds of the former to one of the latter is a good proportion.—E. HOBNAV.

THE FRUIT GARDEN.

PROTECTING FRUIT TREE BLOSSOMS.

MR. HOBDAV, in his remarks upon this subject (see p. 516), says "that in bleak, exposed districts nothing but a glass covering for the finer sorts of wall fruit will in all seasons secure a crop." This I have proved to be sound advice, for on a glass-covered wall for these last fourteen years I have never missed harvesting a full crop of Peaches and Nectarines. This glass-covered wall is nearly 800 ft. in length, and is heated with two rows of 4-in. piping and one small saddle boiler, which raises the temperature inside 8° higher than that outside, and which is quite sufficient to prevent spring frosts from injuring the blossoms, and for ripening the wood in cold autumns. The only difficulty I find in managing the trees, is that the fruit sets so thickly every year that thinning becomes a tedious operation. This year it would have taxed Bishop Colenso's calculating powers to have counted the thinnings, which would, I have no doubt, have furnished a fair crop for all the Peach and Nectarine trees grown on walls in the district. One cause of the fertility of the trees grown in this structure is that the wood is thoroughly ripened every autumn, from having a little artificial heat at command, and another is the soil being particularly suitable for producing healthy growth in the Peach. The turfy surface of a magnesian limestone is used, and without adding any manure to it whatever, only mixing with it a lighter soil, to keep the limestone from getting too solid in dry summers. During growth, liquid manure is used to swell the fruit off, and some of the late varieties of Peaches, such as the *Desse Tardive*, *Barrington*, *Princess of Wales*, and *Salway* swell to a very large size. In the old kitchen garden here, where the situation was very low, being nearly level with the lake, Peaches and Nectarines grown on the south wall were two out of three years failures as far as producing crops were concerned, despite coverings of woollen nettings, frigi domo, and other materials. The best results from protection were where sprigs of Yew or Spruce were used, covered with old herring netting to keep the wind from blowing them off. Neither the Apricot, Peach, nor Nectarine trees could, however, be kept in a healthy state and free from mildew and canker. The late Mr. Mearns, whom I succeeded at Welbeck, tried to renovate some of the old Peach trees on the walls by raising them out of the old borders, and replanting them in turfy soil from the limestone rock; and it is astonishing how some of these trees recovered their vigour, for from a *Teton de Venus* Peach tree I once gathered some fruit 12 oz. in weight. When the new kitchen garden was formed the covering of the principal south walls with glass was determined on, and some healthy young trees were planted; the result has been highly satisfactory up to the present time.

WILLIAM TILLERY.

Welbeck.

FRUIT CROPS IN WORCESTERSHIRE.

THE general failure of outdoor fruits, more particularly Apples, Pears, and Plums, is now universally admitted, but the real cause of failure is by no means so clearly authenticated. We are too apt to attribute the damage wholly to frost, and doubtless such severe frosts as were experienced in the early part of May, when the thermometer indicated upon various occasions from 10° to 12°, with cold, cutting winds, and vegetative power at a minimum, did much damage to such fruits as were then in full blossom, and granting that Pears, Plums, and Cherries suffered to some extent therefrom, still I am inclined to believe with Mr. Fish, after close observation, that failure in these crops cannot be attributed to frost alone. The season was an unusually late one, quite a fortnight later than the average, and as fruit orchards in Worcestershire never presented a more promising appearance, growers fully counted upon reaping a rich harvest, when all at once the destruction of the crops, so far as early varieties of Cherries, Pears, and Plums were concerned, became apparent. But is it wholly to frost that the wreck of our crops of fruits is to be attributed? That stinging frost in the middle of spring, which killed our Pear and Plum bloom did not, most assuredly by direct action, injure our Apple blossoms which were afterwards developed in such profusion; a flimsy weakness of development, antagonistic to vigour, however, pervaded the Apple bloom, which was of short duration; and I firmly believe that immaturity of the wood

had much to do with the failure; the sap was unable to nourish the embryo fruit, and consequently it withered and dropped. Thus one of the severest and latest springs which we have experienced for years, following upon a wet, mild, ungenial autumn and winter, with scarcely a gleam of sun to ripen the wood, is in my opinion one of the chief causes as regards the failure of our early fruits. Protection, we find, did not save the crops, as those upon walls were equally affected with those upon standards. There have been great complaints even in the more favoured districts of Peaches and Nectarines suffering seriously from blister, which is due to impaired vitality and a low temperature. We have an average crop of Peaches and Nectarines upon walls on which not a single tree is without a crop, and yet from these the covers were removed previous to the occurrence of the severe May frosts. Small fruits promise fairly well, but we have no Pears and Plums. On late-flowering Apples and Bitter-sweets there is a crop, but fruits in general are a sad failure in this district.

GEO. WESTLAND.

Witley Court.

Fruiting of *Pyrus japonica*.—Although fruit crops are everywhere a failure this year, I have two trees of this—one scarlet, the other white or blush—and both are well set with fruit. On the scarlet one I can count upwards of sixty fruit, which is borne in clusters of from three to five. The blush is a smaller tree, but quite as well furnished with fruit, in proportion to its size, as the other. Many say their trees rarely ever bear; mine are planted against the house, the aspect of which is north-west; here they bloom somewhat later than on a south aspect, a circumstance which may account for their unusual fertility. The fruit, though very acid, makes one of the best of pickles, but it must not be gathered for such a purpose when ripe.—H. T.

Shanking of Grapes.—I have here two houses for the growth of Muscats, and in some seasons the berries shank badly, occasioned, I suppose, by heavy cropping. Quantity, however, must be had, and I try to put as much in the border in the shape of liquid manure as I take from the Vines in the form of fruit. I have noticed often that shanking begins at the end of the bunches, and on many occasions I have been told that the bunches were too long and did not look well on the dessert dishes. I therefore this season removed from the points of the bunches from 2 in. to 3 in. before they came into flower, and the result is noble, massive clusters, swelling away with great regularity. There is nothing new in taking off the points of bunches; I have done it thirty years ago, but the practice is not generally adopted. It seems, however, to be a step in the right direction as regards getting rid of that which no man knows, I verily believe—how to cure the shanking of Grapes.—R. GILBERT, *Burghley, Stamford*.

Effect of Spring Frosts on Sea-side Vegetation.—During the late severe spring frosts I noticed that the nearer one approached the coast the less observable were the effects of the frost; during the first week in May, Potatoes were killed to the ground with us under a double covering of fish nets, while on the coast about four miles distant they were not injured even where fully exposed. Fruit crops on the contrary are, however, worse on the coast than with us; the withering winds nearly destroyed the trees and bushes, and as a natural consequence the young fruits dropped off. We have abundant crops of bush fruits and Strawberries, also Cherries, Figs, and Pears—some trees on west walls even require thinning considerably. Apples are certainly much better than they have been for several years past, although why they have not all set well is a mystery, as I never saw such a fine bloom, or knew it to expand under more favourable conditions. It is certainly not frost that has made them drop. There is a good prospect of our having plenty of Walnuts, and if we have to deplore a scarcity of Apricots and Peaches, their absence is less felt than when the late-keeping fruits that supply the long winter months are a failure. Taken as a whole I expect that our outdoor fruit crops will fill the fruit-room shelves better than they did last year.—J. GROOM, *Henham*.

Pruning Gooseberries.—Gooseberry bushes require pruning twice a year, viz., in summer and in winter. I have bushes that have been planted about twenty years, and scarcely any of them on a single stem; they therefore throw up a great number of suckers from their centre, which I clear away at this season of the year, and shorten the young growths produced along the main branches to five or six leaves from their base; but, as a rule, if the branches be heavily laden with fruit, there is not that production of young shoots that there is when a scanty crop occurs. Now I hold that the more regularly these young shoots are produced along the main branches, the better will be the prospects of a crop the ensuing year, but I am censured for having young shoots, and told that I must have pruned improperly. My system of winter-pruning is to keep the centre

open, cutting all the young shoots not required to fill up vacancies, &c., back close to the base from which they spring, leaving a sprinkling of young shoots here and there to take the place of branches likely to become diseased and those rendered bare by birds. I do not shorten the points of the main branches until they are likely to overgrow the allotted space. It is said hereabouts Gooseberry bushes should not be pruned, or rarely so. Is that so? Will some one or two experienced cultivators of the Gooseberry oblige me by giving their opinions of the results of both systems?—J. M. D.

THE STEEL GLOVE FOR THE PHYLLOXERA.

This useful article, recently invented in France for the removal of the loose bark, &c., from the stems of Vines, is also used with good effect in removing Moss, &c., from other trees. A great deal of work may be done with it in a very short time, and the stems cleared of much that might afford cover to the eggs of insect enemies. It is very well made, and is lined with canvas to make it

convenient to the hand. The workman with his gloved hand grasps the stem, rubbing the glove up and down, and moving it round the stem removes all loose bark, &c., in an incredibly short space of time. It is formed of small steel chains; it is likely to be useful in our gardens for various purposes, though, so far as we know, it is not yet offered for sale in this country.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Aged Pear Trees.—Among the fruits exhibited by the Massachusetts Horticultural Society at the Centennial (says the "Country Gentleman") were Orange Pears from a tree 235 years old, Endicott Pears from a tree planted by Governor Endicott (Danversport) in 1630, and autumn Pears from a tree planted by Governor Prince in 1630.

Large Apple Orchard.—The "Prairie Farmer" says that the largest Apple orchard in the world belongs to R. A. Whitney, of Franklin Grove, Illinois, and contains 22,000 trees. It would be interesting to know how old the trees are, and what revenue they afford their owner.

The Vineyard at Castle Coch.—The Vines planted in the spring of 1875 in the Marquis of Bute's Vineyard at Castle Coch, near Cardiff, are now looking remarkably well even at this early stage of their growth, and there is every appearance of their carrying a good crop. M. Chauvenet, a Vineyard proprietor from the Côte d'Or, France, has been on a visit to Castle Coch, and expressed a very favourable opinion of them. He thinks the site and soil of the Vineyard all that could be desired, and states that the Vines are looking as well and quite as forward as those in his own Vineyard at Nuits, and he believes, from what he has seen, that the experiment will turn out satisfactorily. We understand that M. Chauvenet will visit Cardiff in the autumn to give the benefit of his experience in wine-making, and we hope that before many years have elapsed we shall have the pleasure and opportunity of tasting wines of home growth.—"Court Journal." [We think the plantation is made on ground too rich to give as good a result as might be obtained in this country.]

THE INDOOR GARDEN.

SPECIMEN DOUBLE-FLOWERED PETUNIAS.

THE Petunia can be grown in many ways; it may be planted out and used as other bedding plants are, flowered in small pots, or grown on into specimens. In the case of the double varieties, of which I am more especially speaking, specimens will be found the most satisfactory way of growing them; in fact, it is only in this manner that the full decorative value of the plant can be realised. With liberal treatment in the way of generous soil and careful attention, the flowers attain dimensions and acquire a colour unattainable under any other system of culture. In order to have large plants propagation must begin early, the kiuds required should be placed in gentle heat in December, and in January and February cuttings may be taken off, which should be inserted singly in thumb pots in a very light sandy soil, and set upon a slight bottom-heat. There they will soon strike root, when they should be removed to the cooler portion of the house, and shifted into 3-in. pots as soon as the roots have fairly touched the side of the cutting-pot. The soil used should be light and rich, very free, with quite one-third of silver-sand added to it. The choice of soil is very important in the present instance, for if at all sour or of a tenacious character the roots will not move, and the plants will become hard and stunted, and if this once take place it is extremely difficult to bring them into free growth again; in fact, the great secret of success in Petunia culture is to keep the wood growing rapidly without check, either through getting pot-bound, lacking atmospheric moisture, or becoming too dry at the root. They must be kept well stopped, as if neglected in this respect, especially during the earlier stages of growth, they will run up lanky and become eventually naked at bottom; the flower-buds, too, must be removed as soon as they appear. The object should be to secure a good base of healthy foliage, and therefore stopping the young shoots should form one of the most important points in their culture during the early part of their growth. It is better to repot often than to give large shifts, as is often practised; as soon as there is enough root to hold the soil together when carefully knocked out of the pot, the plant should be at once put into one a size larger. The soil should neither be rammed nor pressed between the ball and the pot, but merely shaken into its place by means of a gentle tap upon the potting bench; the surface should, however, be made firm, as water will not then run away so rapidly as it otherwise would do, but will gently permeate the whole body of the soil. The compost should be used in a rather moist state, so that immediate heavy waterings may be dispensed with; it is, in fact, better if, after being shifted, they can stand twenty-four hours without water, as in a genial atmosphere, with the soil of a temperature corresponding with that of the house when used, they will in that time strike fresh roots. By successive shifts they may be brought into 16-in. pots, which will be large enough for most purposes: if they have been well attended to they will then form handsome specimens, well clothed with foliage to the rim of the pot, and bearing a quantity of large, handsome flowers. As they advance in growth they will require staking, the shoots being brought out from each other as much as possible; if the shoot be neatly tied to the outer side of the stake, no unsightly effect will thereby be produced. The best place in which to grow them is a span-roofed house, for although they delight in warmth and considerable atmospheric moisture, it must be accompanied by plenty of light, and there must be the means of giving good ventilation when required, an operation in which judgment must be used, as, although plenty of air is required to prevent drawing, yet cold draughts must be at all times avoided. When they have attained the desired size they should be removed to a cooler house. If the pots are, as they should be, well filled with roots, a little manure water may be given occasionally, which will keep the foliage healthy and green, and materially aid the development of the flowers. If the plants have been well managed, the latter will be produced in great abundance, and will last long in good condition.

JOHN CORNHILL.

Byfleet.

TRAINING AND FORCING AZALEAS.

WHAT training Azaleas require should take place immediately they have completed their growth, in order that the young shoots may be readily bent to the required position, and assume a natural appearance, which they will not do if the tying be deferred till the wood becomes ripe and stiff. Of all forms to which Azaleas may be made to conform readily, the pyramidal is the most pleasing, requiring but little tying or attention after they are once put into shape, as the growth they make then is generally uniform and regular, and looks far better than when they are so exceedingly stiff and symmetrical as frequently seen at exhibitions, although there is a great improvement in this respect to what prevailed some few years back when crinoline shapes were all the fashion. In training use as few sticks as possible, and only those made of the best Baltic deal to insure durability, as nothing injures a plant so much as to be frequently piercing the ball, which cannot be done without damaging the roots, and it frequently occurs that many of the decaying ends of the sticks are left in the soil, where they are sure to breed fungi, which are so inimical to the welfare of the plants, that they soon throw them out of health, and ultimately cause their entire destruction. The stumps should therefore be pulled out by means of a pair of pliers, inserting the fresh sticks into the same holes, which, if not required, should be filled in with fine sandy peat. There are few plants better adapted for forcing than Azaleas, or that are so effective and useful when they come into bloom, and to fit them for this purpose they require a course of preparation, so as to get the buds well up and the plants early to rest. This may be done by gradually inuring them to the work in starting them a little sooner each year, and losing no time in getting them back into heat after they have done flowering, in order to get them to complete their growth, when after a few seasons they will come on almost naturally. There are some much better adapted for this purpose than others, and notably so the old Fielder's White, amœna, and Pauline Marder, the latter a double, soft pink-coloured variety, and most valuable in bouquets, where, owing to its great substance of petals, it is very enduring. The forcing at the commencement should be slow and regular, so as to give the buds time to come gradually on, when the flowers will be all the finer and more serviceable: in order to render them more durable, the plants should be elevated as near to the glass as possible, and have all the light obtainable at that early season of the year. It is surprising what a difference this makes in the substance and quality of the blooms, not only of Azaleas, but of all other plants subjected to artificial treatment, a fact that cannot be too strongly impressed on young beginners or those who have not had much experience in early forcing.

The only insects that affect Azaleas to any serious extent are thrips, which, if not seen to as soon as they make their appearance, increase at a rapid rate, and soon damage the plants so much as to destroy the principal leaves. Strong fumigations of Tobacco-smoke will kill all that are hatched; but not so the eggs, and the best way, therefore, is to syringe with Tobacco-water, to which 3 oz. or so of Gishurst or Fowler's Insecticide had been added. This will render it more powerful and penetrating, as otherwise it will not soak through the varnish-like covering with which the eggs are coated. Before this is applied, lay the plants on their sides on a trestle, with a tub or other large vessel underneath to catch the liquid as it drains from them and so prevent waste. In any case, none of it must be allowed to drain down the stems and enter the soil; and to prevent this the plants should not be placed in an upright position till thoroughly drained. After a few hours, to allow time for it to take effect, syringe or give the plants a good washing with clear water from the garden-engine, which will thoroughly cleanse them of any deposit left by the liquid, and wash away any thrips that may be hovering between life and death. S. D.

Imantophyllum miniatum.—This beautiful stove bulb well repays a little extra attention, for at this season large plants of it with brilliant heads of orange flowers, nestling amongst foliage of the deepest green, are highly effective. In order to keep the foliage, however, in good condition, the plants should not be stored in any dark corner, but kept in a conspicuous position, and their foliage is always ornamental.—J. Groom.

THE FLOWER GARDEN.

HARDY FLOWERS IN LONDON GARDENS.

THE warm weather and occasional showers which we have lately experienced have had a good effect on hardy flowers, and those who are fortunate enough to possess a good collection of them, will now be enjoying a floral feast. On the rockwork at Kew there is just now quite a profusion of plants in flower, amongst which we noticed *Orchis foliosa*, producing fine spikes even in the case of small plants; the deep purple-flowered *Delphinium cashmerianum*; and the dwarf rosy-flowered *Phlox ovata* are blossoming abundantly, as are also *Milla laxa*, and the feathery-looking *Dianthus superbus*. Plants of *Sarracenia purpurea* are now well furnished with drooping, reddish-bronze blossoms, rising from among clusters of pitcher-shaped appendages. *Darlingtonia californica* may also be found growing freely here, in company with *Cypripedium spectabile*, which is finely in flower. *Pentstemon glaucus* and *P. cœrulescens* are laden with blossoms, as are also plants of the rosy-flowered *Spiraea palmata*; and white-flowered Foxgloves are thickly studded with blossoms. *Anemone obtusiloba* is likewise covered with pretty white flowers, and the bright yellow-flowered *Chlora perfoliata* is also blooming freely. In open borders *Gaillardias* are becoming very attractive, and notably *G. aristata*, *amblyodon*, *Richardsoni*, and *rigida*. *Paris Daisies* (*Chrysanthemum grandiflorum*) are good plants for the flower garden, as is also the tall-growing yellow-flowered Sweet-scented Evening Primrose (*Oenothera odorata*). The large-flowered Everlasting Pea (*Lathyrus grandiflorus*),

Gunnera scabra.

Sedum cœruleum.

grown as a pillar plant is just now very effective. The double-flowered Scarlet Lychnis and its white variety are now blooming abundantly, as is also the tall-growing *L. Githago*. Plants of the rich crimson-blossomed *Linum grandiflorum* are now very showy, as are also the blue *L. perenne* and the white *L. monogynum*. Amongst other plants in flower may be named *Scabiosa Fischeri*, *Betonica grandiflora*, *Yellow Phloxis*, and abundance of blue *Salvias* and *Veronicas*. The large-flowered Musk (*Mimulus luteus*), growing in the form of tufts, is very pretty, as are also the Pea-blossomed *Nemesia floribunda* and the starry-flowered *Dictamnus*. *Gentiana cruciata* is opening its blossoms, and dense masses of the small bluish-purple-flowered *Specularia Speculum* are very attractive, as are also the stalwart blue and white *Campanula pyramidalis*, *C. Medium Calycanthema*, and the dwarf-growing *C. muralis*. *Geraniums* are still very showy, as are also the pale blue flowers of *Nigella damascena* and common white Pinks. S.

Salting Walks.—Large breadths of gravel are best salted to keep down weeds, and narrow walks also, if there be no danger of the salt being washed into the Grass margins. Several solutions are recommended for killing weeds, but salt is as good and cheap as anything. Solutions that vanish into the ground rapidly soon lose their effect, and the weeds grow again. Salt itself, if washed in by heavy rains as soon as applied, does not keep the weeds down for more than three months, as I have observed frequently. It should be applied during dry weather, and the longer it lies before melting the more lasting will be its effects. A sprinkling just sufficient to whiten the ground will be enough, but there is no harm in giving it stronger. Too weak a dressing acts as a manure, and, as is well known, the strongest dressing after it begins to get spent fetches up an abundant crop of weeds if there be any seeds in the gravel. A fertile cause of weeds in walks is leaving the edgings uncut till the Grasses seed. It is not necessary to cut the edges every time the mowing machine goes over the ground, but they should not be left too long.—J. S.

Gaillardia picta.

Phalangium ramosum.

Heliophila pilosa.

Mountain Coronilla (*C. montana*).

Rusty Foxglove (*Digitalis ferruginea*).

Small Quaking Grass (*Briza minor*).

Cow Parsnip (*Heracleum pubescens*).

Scarlet Lychnis (*L. chalcedonica*).

Houseleek (*Sempervivum tectorum*).

Heuchera micrantha.

Common Everlasting Pea (*Lathyrus latifolius*).

Phalangium Liliago.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

CLEMATIS HENRYI.

FOUR years ago I received this Clematis from the Lawson Company, Edinburgh. During the journey, which was provokingly extended by a fortnight's delay in our Custom House, it had made long, colourless shoots several feet in length, so that when re-potted it was so weakened that two or three months passed ere we had hopes of its recovery. It was put out on the north side of a summer-house, where during the first summer it became so well established that we trusted it out for the winter, only coiling the stems upon the ground and covering them lightly with straw and leaves. That winter proved one of the severest ever known in our valley, the thermometer being one morning 23° below zero, and on a score of other days 10°, 12°, and 15° below that point. C. Henryi was, however, unharmed, as indeed were C. Lawsoniana and C. Symesiana, imported at the same time.

C. Jackmanni is one of the few large-flowered Clematises that are well known here; and it is considered by far the best. That it is still one of the best in England—who value the Clematis so highly—often admit while describing the latest and most improved varieties. But if I were obliged to choose between C. Jackmanni and C. Henryi, I should choose the latter. Henryi bears fewer flowers, it is true, but they are very large. I have just counted thirty-one fully expanded, that average in diameter from tip to tip of sepals 7 in., while the entire plant is permitted to cover a space only 2 ft. by 10 ft. Thus the flowers, if separated, would cover one-third of the area occupied by the plant. One of the flowers, when not quite fully expanded, was placed in a goblet of water upon a mantel-shelf. It lasted eight days in perfection, the sepals spreading out perfectly flat, and measuring just 7½ in. in diameter. Another small vase is now filled with three flowers interspersed with Fern fronds, forming a bouquet that is cooling and refreshing to look upon. The habit of this Clematis, too, is excellent; the leaflets are large, entire, of good substance, similar in shape, and together form as dense a mass of foliage as need be; the sepals, of which there are usually eight, overlap, and though tinted with lavender at first, soon change to a lustrous silver-white. There are few hardy climbers that bear both beautiful flowers and foliage; I know of none that so conspicuously excel in either respect as many of the Clematises. When the improved varieties come to be better known here, there can be little doubt that they will prove as popular with us as they are in England—at least, those varieties hardy enough to stand the climate of New York without protection. English catalogues give July as the time of blooming for C. Henryi; ours began to flower on June 1; it bloomed also last autumn until the buds were blighted by severe frosts. C. Lawsoniana has not yet flowered with us; it has never entirely recovered from its voyage, though slowly improving all the while. C. Symesiana has already borne two of its light blue flowers, which, though imbricated and of fine form, are smaller than those of C. Henryi.

E. S. CARMAN.

River Edge, Bergen Co., New Jersey.

A NATAL GARDEN.

GREAT shrubs of beautiful semi-tropical plants made tangled heaps of purple, scarlet, and white blossoms on every side; the large, creamy bells of the Datura drooped towards the red earth; and many shrubs of that odd bluish-green peculiar to Australian foliage flourished side by side with the sombre-leaved Myrtle; every plant grew in the most liberal fashion; green things which we are accustomed to see in England in small pots shoot up here to the height of Laurel bushes. A screen of scarlet Euphorbia made a brilliant pyramid against a background formed by a hedge of shell-like cluster Roses; and each pillar of the verandah of the little house had its own magnificent creeper. Up one standard an Ipomea twined closely; another pillar was hidden by the luxuriance of a Trumpet Honeysuckle, while a third was thickly covered by an immense Passion-flower. In shady, damp places grew many varieties of Ferns and blue Hydrangeas, whilst other beds were filled with gay patches of Verbenas of every hue and shade. The sweet-scented Verbena is one of the most successful and commonest shrubs in a Natal garden, and just now the large bushes which one sees in every direction are covered with projecting spikes of its small white blossoms. But the chief feature of this garden was Roses—Roses on each side, which-

ever way you turned, and I think of at least 100 different sorts. Not the stiff standard Rose tree of an English garden, with its few precious blossoms to be looked at from a distance and admired with respectful gravity. No: in this garden the Roses grow as they might have grown in Eden—untrained, unpruned, in enormous bushes covered entirely by magnificent blossoms, each of which would have won a prize at a Rose show. There was one Cloth of Gold Rose bush that I shall never forget—its size, its fragrance, its wealth of creamy, yellowish blossoms. A few yards off stood a still bigger and more luxuriant plant some 10 ft. high, covered with the large, delicate, and regular pinkish bloom of the Souvenir de Malmaison. When I talk of "a bush," I only mean the especial bush which caught my eye: I suppose there were fifty Cloth of Gold and fifty Souvenir Rose bushes in that garden. Red Roses, White Roses, Tea Roses, Blush Roses, Moss Roses, and last, not least, the dear, old-fashioned homely Cabbage Rose, sweetest and most sturdy of all. You could wander for acres and acres among fruit trees and plantations of Oaks and Willows and other trees, but you never got away from the Roses. There they were, beautiful delicious things, at every turn; hedges of them, screens of them, and giant bushes of them on either hand. Then, as though nothing should be wanting to make the scene lovely, one could hear through the fragrant silence the tinkling of the little spruit, or brook, at the bottom of the garden, and the sweet song of the Cape canary—the same sort of greenish finch which is the parent stock of all canaries, and whose acquaintance I first made in Madeira; a very sweet warble it is, and the clear flute-like notes sounded so prettily among the Roses. From blossom to blossom lovely butterflies flitted, perching quite fearlessly on the red clay walk just before me, folding and unfolding their big painted wings.

LADY BARKER.

Propagating Kniphofia caulescens.—Those who grow this handsome plant may be glad to know how to increase it. It seems to produce very few seeds, and those few will not all germinate; but finding my plant getting very untidy, I cut it off close to the ground in April. It had two heads, and I separated them and put them into the Cocoa-nut heap; there they have grown well, have made plenty of root, and one is going to flower. The stump left in the ground I did not disturb, and there are already half-a-dozen healthy young shoots well aboveground, and I have no doubt there will be more, and each of these will be easily detached and will make a separate plant.—HENRY N. ELLACOMBE, *Bitton Vicarage.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Hedera Begueriana as a Low Pillar Plant.—I have this trained on a few sticks about 4 ft. high. It has completely hidden them, and now forms a low pillar of shield-like leaves—a fine-foliaged plant indeed.—J. J.

A Climbing Hardy Asparagus.—It ought to be known to those interested in hardy plants that there are one or two climbing, hardy species of Asparagus which are quite hardy and would form graceful objects on lawns.—V.

Scilla verna in Ireland.—Visitors to Howth, Ireland's Eye, and Lambay at this season cannot fail to be impressed with the patches of this beautiful little wildling which enamel the bare turf which carpets the cliffs. The Vernal Squill is also found in the islets and cliffs on the south side of the bay, but not so plentifully.—"Irish Farmers' Gazette."

Saxifraga virginiana fl. pl.—A prettier plant in this way than this double-flowered wild Saxifrage we have never seen. It was discovered by Mr. Joseph S. Adam, in Canaan, Connecticut, and is a perfectly spontaneous production, first noticed as a single plant, but is now multiplied into two or three, one of which is given to the Cambridge Botanical Garden. It is a tall specimen for the species; the stalk bearing seventy to eighty flowers; and each one bears as many petals, in a full rosette, ¼ in. in diameter, pure white. The inflorescence has the look of double-flowered Spiraea filipendula, or of a variety of Cardamine pratensis, which used to be in the gardens. The calyx is unchanged, an imperfect pistil is occasionally found in the centre; but the rest of the flower consist of petals only, in many ranks. We trust it may be preserved in cultivation.—A. GRAY, in "American Naturalist."

Some Plants that have Withstood the Winter.—The following plants have all been wintered in the open ground without any protection:—

Dracena australis	E. paniculatum	Echeandra ternifolia
Abutilon Thompsoni	Libonia floribunda	Phalangium nepalense
Canna Aehiras	Deeringia celosoides variegata	Bomarea Culdasiensis
Trachelospermum jasminoides	Leptospermum lanigerum	Fuchsia splendens
Amarylhis Ackermannii	Hypericum tomentosum	Agapanthus umbellatus
Aster argophyllus	H. hyssopifolium	Primula sikkimensis
Calistemon linearis	Podocarpus chilensis	Agave braehystachya
C. lanceolatus	Helianthemum Fumana	Richardia albo-maculata
C. viridiflorus	Mesembryanthemum uncinatum	Ceterach areurum
Choiisia ternata	Lapageria rosea	Struthiopteris japonica
Amiopia zygomeris	Trachelium coeruleum	Dicksonia antarctica
Gardenia ovata	Matisia Clematis	Athyrium Goringianum
Carmichaelia australis	Tecoma mirabilis	pictum
Eryngium serrata		

—H. N. ELLACOMBE, *Bitton Vicarage, Gloucestershire*, in "Gardeners' Chronicle."

THE KITCHEN GARDEN.

BRUSSELS SPROUTS AND THEIR CULTURE.

THE BRUSSELS SPROUT was at one time thought to be too tender to withstand severe winters, but it has been proved that it is quite as hardy, if not more so, than any other variety of the Brassica tribe. As a rule Brussels Sprouts are only cultivated in private establishments and market gardens, although they well deserve a place in every garden, however small. With a little skill and forethought they may in warm districts be got ready for supplying the table with an excellent vegetable from September till April. In many places the common rule is to sow one good batch in March or April, and let that serve all purposes; where, however, a long supply is desired, this is decidedly a mistake, inasmuch as the Sprouts ought to be made use of as soon as they are ready, otherwise they burst, and are consequently useless. It is therefore obvious that successional sowings should be made to keep up a constant supply. Sowings for early crops are sometimes made in October, and the produce transplanted in the spring, but there are objections to this practice, inasmuch as the plants become stunted, their stalks bent and unshapely during the winter, and when put out they do not grow away with that vigour usually found in spring-sown plants. Plants from this sowing are also liable to run to seed, especially if, after they are up in autumn, the weather be mild and they make free growth before winter sets in. For early crops the best plan is to sow a pinch of seed in a shallow box, well drained, early in January, and place it in a pit or frame where the temperature varies from 40° to 45°. The plants will soon be up, and should be kept close to the glass until they are large enough to handle, when they should be pricked off into other boxes, or out into a bed in a frame. Plenty of air must be admitted to them after they have commenced to grow, and if the weather be favourable in the middle of March they may be planted out-of-doors, on the warmest border that can be spared for them. If the plants be taken up with a good ball of earth, and planted during showery weather, they will grow without a check, and a crop of fine large Sprouts in September will be the result. The first sowing out-of-doors should be made in February or March, the main sowing early in April, and if later supplies be required a small sowing may be made in May or June. When the plants are large enough to be conveniently handled, they should be pricked out in rows into narrow beds or borders 5 in. or 6 in. apart, or more if practicable. The distance asunder for the final planting must in some measure be governed by the space at disposal; but in any case there is nothing gained by overcrowding. Plants for the main crop should be planted at least 2 ft. apart each way, but if 3 ft. can be allowed between the rows all the better. If extra fine Sprouts be desired, 3 ft. from plant to plant each way must be allowed. For early and late plantations it is not necessary to allow quite so much space as for the main crop. There are several varieties of Brussels Sprouts named in seedsmen's catalogues, but it is doubtful if they be really distinct. No doubt much has, and may still be done to improve the Brussels Sprout by persistently carrying out a system of selecting seed from the best and most prolific plants only, and there are few vegetables that will better repay any extra care or trouble incurred in carrying this matter out in a thoroughly practical manner. The best way is to get a good sort and to save one's own seed from the best plants. In the north Brussels Sprouts cannot be had in season so long as in southern districts, but they are oftener grown more finely. The varieties that are considered the best are Imported Brussels, Scrymger's Giant, Dalkeith, Roseberry, and Albert Sprouts.

Brussels Sprouts will succeed in almost any kind of soil, provided it be well and deeply cultivated, and fairly manured. Poor sandy soil will require a heavy dressing of good manure whilst lime and burnt clay may be beneficially applied to cold clayey land, just previous to planting, in preference to rank manure, which would have a tendency to produce gross open Sprouts instead of the close, medium-sized buttons that are so much appreciated. Frequent stirrings of the soil, general clean culture, and removing decaying leaves, add to their growth and cleanly appearance, and ought to receive attention.

As regards earthing up the stems, there has been much dispute as to the merits and demerits of the practice, but I have seen them grown both with and without that assistance, with much about the same result. In exposed places, however, earthing up is certainly to be recommended, in order to enable them to resist the force of the wind; but, as Brussels Sprouts, unlike Cabbage or Broccoli, bear all up the stems, it is not desirable to bury them to any great depth beyond giving them necessary support. The Cabbage-like heart should not be cut off from the centre of the plant until the crop is fit for gathering. The London market gardeners prefer, as a rule, stems of medium length, from which they think they get the hardest and best sprouts; with them, however, Brussels Sprouts are chiefly grown as catch crops. Good soakings of manure water, given to Brussels Sprouts during dry weather, will help to keep them in a vigorous and healthy growing state. In gathering, Brussels Sprouts are frequently broken from the stems of the plants, and sometimes with a portion of the stem adhering to them; but this is a mistake, inasmuch as it destroys the second crop of young Sprouts. A sharp knife should always be employed to cut off the Sprouts, leaving as much spur as possible without impairing the size of the Sprout. The largest and hardest should always be gathered first, in case they should burst, and consequently become spoiled. S.

CULTURE OF SPINACH.

AS FAR back as the year 1351 we find Spinach included among different vegetables consumed by the monks on fast days. It has been in common cultivation in England for more than 300 years, and, according to one authority, it was prepared for table at that period much the same as at present. Spinach is a wholesome vegetable, and if it required more skill in its cultivation no doubt it would be more highly appreciated. On poor soils in dry seasons it is, however, somewhat difficult to manage, and even the winter crops canker and decay; in fact, in some gardens the winter crop is often the cause of much anxiety. On good soils, however, Spinach will grow freely, and in a moist season in particular will yield abundantly. For the summer and autumn crops the ground cannot well be made too rich nor dug too deeply, and then it attains a high degree of succulency, but for the winter produce it is not necessary for the land to be made so rich. It is possible to fall into the same error in selecting the situation for Spinach to stand the winter as it is in choosing the site for Broccoli. Instead of selecting warm and sheltered nooks, and land heavily manured, it should rather be on an exposed aspect, one that is swept by the autumn breezes, that have a hardening influence, and the ground should be moderately rich. When plants have been grown tenderly and produce large, succulent foliage, they are not in such good condition for withstanding the vicissitudes of winter as they otherwise would be. In the confinement of a walled-in kitchen garden, with a very rich soil, Spinach will not stand the winter so well as when planted in a more exposed situation, and in only a moderately rich soil. In the highly-manured soil of a kitchen garden the growth is too succulent and tender, and on the first appearance of frost the plants are laid prostrate. Those produced in more exposed positions, though they do not develop into so much bulk, make a more sturdy growth, which is better able to withstand the winter.

We have two sorts of Spinach in general cultivation—the Round and the Prickly. The leaves of the latter are arrow-shaped and rough, and of the former round and smooth. The Round-leaved grows the fastest, is the largest and most succulent, and, therefore, is the sort used for the summer and autumn supply; the other being much more hardy, is grown to supply the table during winter and early spring. We begin to sow the Round Spinach as early in the new year as the weather will permit, and successional sowings of the same sort should be made until the end of July. Two or three sowings of the Rough-leaved, or Prickly-seeded, should be sown during August; and lest the autumn should be very fine and mild, it is the safest plan to make another sowing or two early in September. When the seed is sown too early, the plants get too forward, and are sure to perish during winter. The seed should be sown in drills about 1 in. deep, and the rows should be 14 in. apart. The best position for summer Spinach is

between rows of Peas or Broad Beans. The Peas and Beans need not be sown any wider than ordinarily to accommodate the Spinach, as the latter will be off the ground before it interferes with them. When Spinach is growing between two rows of Peas, and it is no longer required for use, the best plan is to pull it up, and use it as a mulching for the Peas. The seed should be sown thinly, and if the plants come up too thickly they should be thinned before they get crowded. I grow them till the leaves are 2 in. long, and then the thinnings are useful. I sow part of the winter crop on ground that has been occupied with Broad Beans or Peas, and the other part I sow in an exposed situation outside the kitchen garden proper. If the ground have been well manured for the previous crop, it will not be necessary to add any for the Spinach. This crop, for which the ground should be well dug, must of necessity be sown in rows 1 ft. apart. The winter crop sometimes proves a failure, which may be attributed to two or three causes. It is a common error to sow the seed too thickly, and to allow the plants to stand too crowded till they spoil each other. When the thinning is delayed too long, the mutual shelter which they afford each other is taken away, and the plants that are to form the permanent crop are checked in their development. When the plants are not thinned early they had better not be thinned at all, and the cultivator, if he begrudges the labour of thinning, had better sow thinly in the first place. Sometimes water stands about the plants without being able to drain away; this often causes decay, and leaves blanks in the bed; hence the necessity of the ground being well broken up, and the surface kept loose and open. Spinach has not yet become a popular vegetable with cottagers, but when properly cooked and served up it is well worth attention. K. R.

Early Peas.—These, like all other vegetables, are later this year than usual. We commenced gathering Ringleader from a south border on June 20; they were started in pots, and planted out when about 3 in. or 4 in. high, on March 14. On the same day we sowed on the same border The Shah, William the First, and Kentish Invicta; The Shah and Invicta were fit to gather on the 22nd inst., and William the First on the 23rd inst.; there was thus very little time gained by early sowing, even with the assistance of glass to start them, but this has been an exceptional season. Usually we gain a week by starting them in pots in gentle heat, and planting them out about the first or second week in March. The long period of cold nights and days during March, April, and May, retarded the growth of the early crop, and enabled those that were sown later to closely compete with them. There is a much greater difference between early Potatoes planted at various times. The Potatoes in our first early borders are all dug; in fact, the skins of the last taken up on the 23rd inst. were assuming a ripe tinge and firmness, but those on succession borders, although warmly situated, are scarcely yet fit to dig. The first lot were of course protected with straw mats during the cold weather that prevailed during the spring, and had in addition a warm, sunny spot.—E. HOBDDAY.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Two Good Cucumbers.—We have some pits planted with alternate plants of Telegraph and Hedsor Prolific, and it would be difficult to say which is best; they set two or three fruits at each joint, and, as they average from 15 in. to 18 in. long, they are even more serviceable than those that reach 2½ ft. to 3 ft. I have in former years grown some of these long sorts, but for the future I shall confine our stock to Telegraph and Hedsor only, as being kinds best suited for all seasons.—J. GROOM, *Henham*.

Birds, Insects, and Peas.—A correspondent of "Science Gossip," speaking of sparrows, which came in flocks and nipped off his Peas down to the petioles as soon as they had fairly shot above ground, was surprised to find that the better he succeeded in keeping off the birds the faster his Peas disappeared. This led him to investigate the matter more attentively, and he noticed that the young leaves were notched in a manner not at all likely to be the work of a bird's bill. Ultimately he discovered his real foes in the striped Pea weevil. The reputation of these pertinacious birds for destructiveness in this particular line is so well-established, that it might have been supposed they had come for the Peas, of which they are fond, and found an animal diet they liked better still. This does not appear to have been the case, however, for though the attention of the sparrows was afterwards encouraged, and measures taken which soon resulted in the total rout of the real enemy, the Peas were never afterwards injured. The writer says he has seen whole fields of Peas destroyed by this insect. Lime, soot, or finely powdered road dust, or all of them mixed together, dusted over the crops in early morning, while the dew lies upon them, he finds spoils the appetite of these pests, and if it does not absolutely destroy them, does what some people would perhaps prefer it should do—drives them away to neighbours' crops.

PLATE LXXX.

THE COLCHICUMS.

(WITH A COLOURED FIGURE OF *C. SPECIOSUM*).

Drawn by H. HYDE.

THE genus *Colchicum*, or Autumn Meadow Saffron, consists of hardy plants that flower in the autumn just when summer-blooming plants have lost their freshness, and when the days begin rapidly to shorten. Unlike many bulbous plants, their presence in the ground early in spring, when the borders are being prepared for summer-flowering plants, is not likely to be overlooked, for after the flowers have disappeared in autumn, we find no trace of them aboveground during the winter months, but amongst the earliest harbingers of spring appear the vigorous leaf-stems, bearing three or more leaves, and carrying with them the seed-pod or capsule, as shown in the subjoined woodcut. Last spring we were surprised by a seemingly unaccountable freak of Nature. We received early the previous autumn a case of bulbs of *Colchicum speciosum* from the Caucasus; they were immediately planted, but did not flower; however, in the spring the foliage appeared, and with it seed-capsules containing perfect seeds! We inquired of a well-known botanist—"Were the flowers in

Colchicum speciosum with Seed-pod.

the bulb-tunic abortive, and yet the ovaries fertilized? If not, whence the seed and its capsules?" His reply was as follows: "Perhaps the fertilization was effected by means of concealed abortive and inconspicuous flowers, as in the case of apetalous Violets." We presume, then, that this was the case with all, for all fruited; it only shows, in some cases at least, that the action of sunlight and insect agency as aids to fertilization are apparently not necessary. The species and varieties most worthy of cultivation are *C. autumnale*, the well-known British species, with its many varieties, varying in colour from deep purple, rosy-purple, and rose to pure white, while some forms are more or less striped with white; the same species has also several very beautiful double forms. *C. byzantinum* is a noble species, the petals of which are of good substance and very regular in outline—the whole flower most perfect in form. Of this species there is also a handsome form with variegated foliage, *C. variegatum*, and another very beautiful kind named *C. Parkinsoni*—the latter, which is referred to in *THE GARDEN*, Dec. 2, 1876, has the flowers chequered in a manner somewhat similar to *Fritillaria Meleagris*; this, no doubt, gave rise to the name tessellatum as applied to *C. variegatum*.

Lastly, we come to the subject of our plate, *C. speciosum*, which is probably the noblest plant of the family. It is

a native of the Caucasus, and it is also said to inhabit the provinces of Mingrelia, Iberia, the Suwant, Lenkoran, and the south-west shores of the Caspian Sea. Although this species varies a little in point of colouring, the annexed illustration in no way exaggerates the beauty of the plant or its size, but may be regarded as a good typical specimen; a few, however, are a little darker in colouring, but not sufficiently distinct to be otherwise classified; like *C. byzantinum* it is exceedingly floriferous, as indeed are all the section more or less, each bulb throwing up many flowers. There are many other species of *Colchicum* well worthy of cultivation, but those just enumerated may be considered the best for decorative purposes.

As regards cultivation, all the species may be grown successfully in ordinary garden borders; but, to have them in perfection, choose a situation fully exposed to the sun, with the soil of a sandy character—in fact, such a spot as is likely to dry up during summer—here they will luxuriate, and enjoy the autumn, winter, and early spring rains. In such a situation *Iris iberica* also succeeds remarkably well.

Colchester.

FRED. HORSMAN.

A SIXTEENTH CENTURY SECATEUR.

SECATEURS are far from being very modern inventions. Here is the

figure of a somewhat ornamental one, actually made in France in the sixteenth century; probably they are even of more ancient date. The use of well-formed leaden pipes, turbines, &c., to water the

gardens in Roman houses before the beginning of the Christian era rather detracts from one's wonder at various "recent improvements." Notwithstanding, however, the antiquity of the secateur, it has never become common in our gardens, the small and handy pruner's secateur has been, however, a good deal used in various English gardens of late years, and is found in its best forms to be a little implement that does its work well and saves time.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 527).

Pear.

- (1) *Falstaff*. I warrant they would whip me with their fine wits till I were as crestfallen as a dried Pear.
Merry Wives of Windsor, act iv., sc. 5.
- (2) *Parolles*. Your virginity, your old virginity, is like one of our French withered Pears, it looks ill, it eats drily; marry, 'tis a withered Pear; it was formerly better; marry, yet 'tis a withered Pear.
All's Well That Ends Well, act i., sc. 1.
- (3) *Clown*. I must have Saffron to colour the Warden pies.
Winter's Tale, act iv., sc. 2.
- (4) *Mercutio*. O, Romeo . . . thou a Popering Pear.
Romeo and Juliet, act ii., sc. 1.

If we may judge by these few notices, Shakespeare does not seem to have had much respect for the Pear, all the references to the fruit being more or less absurd or unpleasant. Yet there were good Pears in his day, and so many different kinds that Gerarde declined to tell them at length, for "the stocke or kindred of Pears are not to be numbered; every country hath his peculiar fruit, so that to describe them apart were to send an owle to Athens, or to number those things that are without number."

Of these many sorts Shakespeare mentions by name but two, the Warden and the Popering, and it is not possible to identify these with modern varieties with any certainty. The Warden was probably a general name for large keeping and stewing Pears, and the name was said to come from the Anglo-Saxon *wearden*, to keep or preserve, in allusion to its lasting qualities. In Parkinson's time the name was still in use, and he mentions two varieties, "The Warden or Lukewards Pear are of two sorts, both white and red, both great and small." (The name of Lukewards seems to point to St. Luke's Day, October 18, as perhaps the time either for picking the fruit or for its ripening). "The Spanish Warden is greater than either of both the former, and better also." And he further says, "The Red Warden and the Spanish Warden are reckoned amongst the most excellent of Pears, either to bake or to roast, for the sick or for the sound—and indeed the Quince and the Warden are the only two fruits that are permitted to the sick to eat at any time."

I can find no guide to the identification of the Popering Pear, beyond Parkinson's description—"The summer Popperin and the winter Popperin, both of them very good, firm, dry Pears, somewhat spotted and brownish on the outside. The green Popperin is a winter fruit of equal goodnesse with the former." It was probably a Flemish Pear, and may have been introduced by the antiquary Leland, who was made Rector of Popering by Henry VIII. The place is further known to us as mentioned by Chaucer:—

A knyght was fair and gent
In batail and in tornament,
His name was Sir Thopas.
Alone he was in fer contre,
In Flaundes, al beyonde the se,
At Popering in the place.

As a garden tree the Pear is not only to be grown for its fruit, but as a most ornamental tree. Though the individual flowers are not, perhaps, so handsome as the Apple blossoms, yet the growth of the tree is far more elegant; and an old Pear tree, with its curiously roughened bark, its upright, tall, pyramidal shape, and its sheet of snow-white blossoms, is a lovely ornament in the old gardens and lawns of many of our country houses. It is now considered a British tree, but it is probably only a naturalized foreigner, originally introduced by the Romans.

Peas.

- (1) *Iris*. Ceres, thou bounteous lady! thy rich leas
Of Wheat, Rye, Barley, Vetches, Oats, and Peas.
Tempest, act iv., sc. 1.
- (2) *Carrier*. Pease and Beans are as dank here as a dog,
1st Henry IV., act ii., sc. 1—(see Beans).
- (3) *Biron*. This fellow picks up wit, as pigeons Peas.
Love's Labour's Lost, act v., sc. 2.
- (4) *Bottom*. I had rather have a handful or two of dried Peas.
Midsommer Night's Dream, act iv., sc. 1.
- (5) *Fool*. That a shelled Peascod?
King Lear, act i., sc. 4.
- (6) *Touchstone*. I remember the wooing of a Peascod instead of her.
As You Like It, act ii., sc. 1.
- (7) *Molechio*. Not yet old enough to be a man, nor young enough for a
boy, as a Squash is before 'tis a Peascod, or a Codling when 'tis
almost an Apple.
Twelfth Night, act i., sc. 5.
- (8) *Hostess*. Well, fare thee well! I have known thee these twenty-five
years come Peascod time.
2nd Henry IV., act ii., sc. 4.
- (9) *Leontes*. How like, methought, I then was to this kernel, this
Squash, this gentleman.
Winter's Tale, act i., sc. 2.
- (10) *Peascod, Pease Blossom, and Squash*—dramatis personæ in *Mid-
summer Night's Dream*.

There is no need to say much of Peas, but it may be worth a note in passing that in Old English we seldom meet with the word Pea. The singular name is Peas or Pease, of which the plural is Peason. The Squash is the young Pea, before the Peas are formed in it, and the Peascod is the ripe shell of the Pea before it is shelled. The garden Pea (*Pisum sativum*) is the cultivated form of a plant found in the south of Europe, but very much altered by cultivation. It was probably not introduced into England as a garden vegetable long before Shakespeare's time. It is not mentioned in the old lists of plants before the sixteenth century, and Fuller tells us that in Queen Elizabeth's time they were brought from Holland, and were "fit dainties for ladies, they came so far, and cost so dear."

The beautiful ornamental Peas (Sweet Peas, Everlasting Peas, &c.), are of a different family (*Lathyrus*, not *Pisum*), but very closely allied. There is a curious amount of folklore connected with Peas, and in every case the Peas and Peascods are connected with wooing the lasses. This explains *Touchstone's* speech (No. 6). Braud gives several instances of this, from which one stanza from "Browne's Pastorals" may be quoted:

The Peascod greene, oft with no little toyle,
He'd seek for in the fattest, fertil'st soile,
And end it from the stalke to bring it to her,
And in her bosom for acceptance wooe her.

Peony (see Piony).

Pepper.

Pepper and Peppercorns are mentioned in Shakespeare, but, like Mustard, only as the condiment, and with no reference to the plant, which in Shakespeare's time was only known in England from foreign descriptions, and from fragments of the tree sent home as curiosities.

Pig-nuts.

Caliban. I prythee let me bring thee where crabs grow, and I with my long nails will dig thee Pig-nuts.

Tempest, act ii., sc. 2.

Pig-nuts or Earth-nuts are the tuberous roots of *Couopodium denudatum* (*Bunium flexuosum*), a common weed in old upland pastures; it is found also in woods. This root is really of a pleasant flavour when first eaten, but leaves an unpleasant taste in the mouth. It is said to be much improved by roasting, and to be then quite equal to Chestnuts. Yet it is not much prized in England except by pigs and children, who do not mind the trouble of digging for it. But the root lies deep, and the stalk above it is very brittle, and "when the little 'howker' breaks the white shank he at once desists from his attempt to reach the root, for he believes that it will elude his search by sinking deeper and deeper into the ground" (John-

stone). I have never heard of its being cultivated in England, but it is cultivated in some European countries, and much prized as a wholesome and palatable root.

Pine.

- (1) *Prospero*. She did confine thee,
Into a cloven Pine;
It was mine art,
When I arrived and heard thee, that made gape
The Pine and let thee out.
Tempest, act i., sc. 2.
- (2) *Suffolk*. Thus droops this lofty Pine and hangs his sprays.
2nd Henry VI., act ii., sc. 3.
- (3) *Prospero*. And by the spurs plucked up
The Pine and Cedar.
Tempest, act v., sc. 1.
- (4) *Agamemnon*. As knots, by the conflux of meeting sap,
Infect the sound Pine, and divert his grain
Tortive and errant from his course of growth.
Troilus and Cressida, act i., sc. 3.
- (5) *Antony*. Where yonder Pine doth stand
I shall discover all.
This Pine is backed
That overtopped them all.
Antony and Cleopatra, act i., sc. 3.
- (6) *Belarius*. As the rudest wind
That by the top doth take the mountain Pine,
And make him stoop to the vale.
Cymbeline, act iv., sc. 2.
- (7) *1st Lord*. Behind the tuft of Pines I met them.
Winter's Tale, act ii., sc. 1.
- (8) *Richard*. But when from under this terrestrial ball
He fires the proud top of the eastern Pines.
Richard II., act iii., sc. 2.

The Pine is the established emblem of everything that is "high and lifted up," but always with a suggestion of dreariness and solitude. So it is used by Shakespeare and by Milton, who always associated the Pine with mountains; and so it has always been used by the poets, even down to our own day. Thus Tennyson—

They came, they cut away my tallest Pines—
My dark tall Pines, that plumed the craggy ledge—
High o'er the blue gorge, and all between
The snowy peak and snow-white cataract
Fostered the callow eaglet, from beneath
Whose thick mysterious boughs in the dark morn
The panther's roar came muffled while I sat
Down in the valley.

Complaint of Ænon.

Sir Walter Scott similarly describes the tree in the pretty and well-known lines—

Aloft the Ash and warrior Oak
Cast anchor in the rifted rock;
And higher yet the Pine tree hung
His shattered trunk, and frequent flung,
Where seemed the cliffs to meet on high,
His boughs athwart the narrow sky.

Yet the Pine which was best known to Shakespeare, and perhaps the only Pine he knew, was the *Pinus sylvestris*, or Scotch Fir, and this, though flourishing on the highest hills where nothing else will flourish, certainly attains its fullest beauty in sheltered lowland districts. There are probably much finer Scotch Firs in Devonshire than can be found in Scotland. This is the only indigenous Fir, though the *Pinus Pinaster* claims to be a native of Ireland, some cones having been supposed to be found in the bogs, but the claim is not generally allowed—there is no proof of the discovery of the cones; and yet it has become so completely naturalized on the coast of Dorsetshire, especially about Bournemouth, that it has been admitted into the last edition of Sowerby's "English Botany."

But though the Scotch Fir is a true native, and was probably much more abundant in England formerly than it is now, the tree has no genuine English name, and apparently never had. Pine comes directly and without change from the Latin, *Pinus*, as one of the chief products, pitch, comes directly from the

Latii, pin. In the early vocabularies it is called "Pin-treow," and the cones are "Pin-nutties." We also find "Fyre-tree," which is a true English word meaning the "Fire-tree;" but I believe that "Fir" was originally confined to the wood, from its large use for torches, and was not till later years applied to the living tree.

The sweetness of the Pine seeds, joined to the difficulty of extracting them, and the length of time necessary for their ripening, did not escape the notice of the emblem-writers of the sixteenth and seventeenth centuries. With them it was the favourite emblem of the happy results of persevering labour. Camerarius, a cotemporary of Shakespeare and a great botanist, gives a pretty plate of a man holding a Fir-cone, with this moral—"Sic ad virtutem et honestatem et laudabiles actiones non nisi per labores ac varias difficultates perveniri potest, at postea sequuntur suavissimi fructus." He acknowledges his obligation for this moral to the proverb of Plautus—"Qui e nucce nucleum esse vult, frangat nucem."—"Symbolorum," &c., 1590).

In Shakespeare's time a few of the European Conifers were grown in England, including the Larch, but only as curiosities. The very large number of species which now ornament our gardens and Pineta from America and Japan were quite unknown. The many uses of the Pine—for its timber, production of pitch, tar, resin, and turpentine—were well known and valued. Shakespeare mentions both pitch and tar.

Piony.

Iris. Thy banks with Pionied and Lilled brims,
Which spongy April at thy best betrimms,
To make cold nymphs chaste crowns.

Tempest, act iv., sc. 1.

There is much dispute about this passage, the dispute turning on the question whether "Pionied" has reference to the Peony flower. The word by some is supposed to mean only "digged," and it doubtless often had this meaning, though the word is now obsolete, and only survives with us in "pioneer." But this reading seems very tame, tame in itself, and doubly tame when taken in connection with the Lilies and the "nymphs' chaste crowns." I shall assume, therefore, that the flower is meant, spelt in its old form of "Piony," instead of Peony or Pæony.

The Pæony (*P. corallina*) is sometimes allowed a place in the British flora, having been found apparently wild at the Steep Holmes in the Bristol Channel and a few other places, but it is now considered certain that in all these places it is a garden escape. Gerarde gave one such habitat:—"The male Peonie groweth wilde upon a Coneyberry in Betsome, being in the parish of Southfleet, in Kent, two miles from Gravesend, and in the ground sometimes belonging to a farmer there, called John Bradley;" but on this his editor adds the damaging note—"I have been told that our author himself planted that Peionee there, and afterwards seemed to find it there by accident; and I do beleevve it was so, because none before or since have ever seen or heard of it growing wild since in any part of this kingdome."

But, though not a native plant, it had been cultivated in England long before Shakespeare's and Gerarde's time. It occurs in most of the old vocabularies from the tenth century downwards, and in Shakespeare's time the English gardens had most of the European species that are now grown, including also the handsome double-red and white varieties. Since his time the number of species and varieties has been largely increased by the addition of the Chinese and Japanese species, and by the labours of the French nurserymen, who have paid more attention to the flower than the English.

In the hardy flower garden there is no more showy family than the Pæony. They have flowers of many colours, from almost pure white and pale yellow to the richest crimson, and they vary very much in their foliage, most of them having large fleshy leaves, "not much unlike the leaves of the Walnut tree," but some of them having their leaves finely cut and divided, almost like the leaves of Fennel (*P. tenuifolia*). They further vary in that some are herbaceous, disappearing entirely in winter, while others, Moutan or Tree Pæonies, are shrubs; and in favourable seasons, when the shrub is not

injured by spring frosts, there is no grander shrub than an old Tree Pæony in full flower.

Of the many different species the best are the Moutans, which, according to Chinese tradition, have been grown in China for 1500 years, and which are now produced in great variety of colour; *P. corallina*, for the beauty of its coral-like seeds; *P. cretica*, for its earliness in flowering; *P. tennifolia*, single and double, for its elegant foliage; *P. Whitmaniana*, for its pale yellow, but very fleeting flowers, which, before they are fully expanded, have all the appearance of immense Globe-flowers (*Trollius*); *P. lobata*, for the wonderful richness of its bright crimson flowers; and *P. Whiteji*, a very old and very double form of *P. edulis*, of great size, and most delicate pink and white colour.

Pippin (see Apple).

Plantain.

- (1) *Costard.* O sir, a Plantain, a Plantain, a plain Plantain, no l'envoy, no l'envoy, no salve, sir, but a Plantain.
Moth. By saying that a costard was broken in a shin
Then called you for the l'envoy.
Costard. True! and I for a Plantain.
Love's Labour's Lost, act iii., sc. 1.
- (2) *Romeo.* Your Plantain leaf is excellent for that.
Benvolio. For what, I pray thee?
Romeo. For a broken shin.
Romeo and Juliet, act i., sc. 2.
- (3) *Troilus.* As true as steel, as Plantage to the moon.
Troilus and Cressida, act iii., sc. 2.

The most common old names for the Plantain were Waybread (corrupted to Weybread, Wayborn, and Wayfern), and Ribwort. It was also called Lamb's-tongue and Kemps, while the flower-spike with the stalk was called Cocks and Cockfighters (still so called by children). The old name of Ribwort was derived from the ribbed leaves, while Waybread marked its universal appearance, scattered by all roadsides and pathways, and literally bred by the wayside. It has a similar name in German, *Vegetritt*, that is, *Waytread*; and on this account the Swedes name the plant *Wagbredblad*, and the Indians of North America *Whiteman's Foot*, for it springs up near every settlement the colonists make, having sprung up after the English settlers not only in America, but also in Australia and New Zealand:—

Wheresoe'er they move before them
Swarms the stinging fly, the Ahmo,
Swarms the bee, the honey-maker:
Wheresoe'er they tread, beneath them
Springs a flower unknown among us,
Springs the "White man's foot" in blossom.

Longfellow's Hiawatha.

And "so it is a mistake to say that Plantain is derived from the likeness of the plant to the sole of the foot, as in Richardson's Dictionary. Rather say, because the herb grows under the sole of the foot"—(Johnstone). How, or when, or why the plant lost its old English names to take the Latin name of Plantain, it is hard to say. It occurs in a vocabulary of the names of plants of the middle of the thirteenth century—"Planago, Plantheime, Weibrede," and apparently came to us from the French, "*Cy est assets de Planteyne, Weybrede.*" (Walter de Biblesworth, thirteenth century.) But I believe Shakespeare is almost the earliest writer that uses the name, though it is very certain that he did not invent it; but "Plantage" (No. 3), which is doubtless the same plant, is peculiar to him.

It was as a medical herb that our forefathers chiefly valued the Plantain, and for medical purposes its reputation was of the very highest. In a book of recipes (*Lacnunga*) of the eleventh century, by Alfric, is an address to the Waybread, which is worth extracting at length:—

And thou, Waybread!
Mother of worts,
Open from eastward,
Mighty within;
Over thee carts creaked,
Over thee Queens rode,
Over thee brides bridalled,
Over thee bulls breathed,
All these thou withstood'st
Venom and vile things
And all the loathly ones
That through the land rove.

(*Cockayne's Translation*).

In another earlier recipe book the Waybread is prescribed for twenty-two diseases, one after another; and in another of the same date we are taught how to apply it:—"If a man ache in half his head . . . delve up Waybread without iron ere the rising of the sun, bind the roots about the head with Crosswort by a red fillet, soon he will be well." But the Plantain did not long sustain its high reputation, which, even in Shakespeare's time had become much diminished. "I find," says Gerarde, "in ancient writers many good-morrowes, which I think not meet to bring into your memorie againe; as that three roots will cure one griefe, four another disease, six hanged about the neck are good for another maladie, &c., all which are but ridiculous toys." Yet the bruised leaves still have some reputation as a styptic and healing plaster among country herbalists, and perhaps the alleged virtues are not altogether fanciful.

As a garden plant, the Plantain can only be regarded as a weed and nuisance, especially on lawns, where it is very difficult to destroy them. Yet there are some curious varieties which may claim a corner where botanical curiosities are grown. The Plantain seem to have a peculiar tendency to run into abnormal forms, many of which will be found described and figured in Dr. Masters' "Vegetable Teratology," and among these forms are two which are exactly like a double green Rose, and have been cultivated as the Rose Plantain for many years. They were grown by Gerarde, who speaks of "the beauty which is in the plant," and compared it to "a fine double Rose of a hoary or rusty greene colour." Parkinson also grew it and valued it highly.

Plums, with Damsons and Prunes.

- (1) *Constance*. Give grandam kingdom, and it grandam will give it a Plum, a Cherry, and a Fig.
King John, act ii., sc. 1.
- (2) *Hamlet*. The satirical rogue saith that old men have grey beards, their faces are wrinkled, their eyes purging thick amber and Plumb-tree gum.
Hamlet, act ii., sc. 2.
- (3) *Simpcoor*. A fall off a tree.
Wife. A Plum tree, master.
Glooucester. Marry, thou lovest Plums well that wouldest venture so.
Simpcoor. Alas! good master, my wife desired some Damsons, and made me climb, with danger of my life.
2nd Henry VI., act ii., sc. 1.
- (4) *Evans*. I will dance and eat Plums at your wedding.
Merry Wives of Windsor, act v., sc. 5.
- (5) The mellow Plum doth fall, the green sticks fast,
Or being early plucked is sour to taste.
Venus and Adonis.
- (6) Like a green Plum that hangs upon a tree,
And falls through wind before the fall should be.
Passionate Pilgrim.
- (7) *Slender*. Three veneys for a dish of stewed Prunes.
Merry Wives of Windsor, act i., sc. 1.
- (8) *Falstaff*. There's no more faith in thee than in a stewed Plum.
1st Henry IV., act iii., sc. 3.
- (9) *Clown*. Longing (saying your honour's presence) for stewed Prunes.
And longing, as I said, for Prunes.
You being then, if you be remembered, cracking the stones
of the said Prunes.
Measure for Measure, act ii., sc. 1.
- (10) *Clown*. Four pounds of Prunes, and as many of Raisins of the sun.
Winter's Tale, act iv., sc. 2.
- (11) *Falstaff*. Hang him, rogue; he lives upon mouldy stewed Prunes and dried cakes.
2nd Henry IV., act ii., sc. 4.

Plums, Damsons, and Prunes may conveniently be joined together, Plums and Damsons being oftener used synonymously (as in No. 3), and Prunes being the dried Plums. The Damsons were originally, no doubt, a good variety from the East, and nominally from Damascus. They seem to have been considered great delicacies, as in a curious allegorical drama of the fifteenth century, called "La Nef de Sante," of which an account is given by Mr. Wright:—"Bonne-Compagnie, to begin the day, orders a collation, at which, among other things, are served Damsons (Prunes de Damas), which appear at this time to

have been considered as delicacies. There is here a marginal direction to the purport that if the morality should be performed in the season when real Damsons could not be had, the performers must have some made of wax to look like real ones."—"History of Domestic Manners," &c.). The garden Plums are a good cultivated variety of our own wild Sloe, but a variety that did not originate in England, and may very probably have been introduced by the Romans. The Sloe and Bullace are, speaking botanically, two sub-species of *Pyrus communis*, while the Plum is a third sub-species (*P. communis domestica*). The garden Plum is occasionally found wild in England, but is certainly not indigenous. It is somewhat strange that our wild plant is not mentioned by Shakespeare under any of its well-known names of Sloe, Bullace, and Blackthorn. Not only is it a shrub of very marked appearance in our hedgerows in early spring, when it is covered with its pure white blossoms, but Blackthorn staves were indispensable in the rough game of quarterstaff, and the Sloe gave point to more than one English proverb: "as black as a Sloe," was a very common comparison, and "as useless as a Sloe," or "not worth a Sloe," was as common.

Sir Amys answered, tho'
"I give thee thereof not one Sloe!
Do right all that thou may!"

Amys and Amyllion—Ellis's Romances.

Though even as a fruit the Sloe had its value, and was not altogether despised by our ancestors, for thus Tusser advises—

By the end of October go gather up Sloes,
Have thou in readiness plenty of those;
And keep them in bed-straw, or still on the bough,
To stay both the flux of thyself and thy cow.

As soon as the garden Plum was introduced, great attention seems to have been paid to it, and the gardeners of Shakespeare's time could probably show as good Plums as we can now. "To write of Plums particularly," said Gerarde, "would require a peculiar volume. . . . Every clymate hath his owne fruite, far different from that of other countries; my selfe have threescore sorts in my garden, and all strange and rare; there be in other places many more common, and yet yearly commeth to our hands others not before knowne."
H. N. ELLACOMBE.

(To be continued).

Cats and Small Birds.—We often hear the small birds, and not least the tits, spoken of as enemies in our gardens, but little seems to be thought of the many enemies with which they have to contend. Having a fair amount of shrubbery, with more than an average of small birds' nests, I can safely say that in scarcely more than one in ten are the young birds reared, and this in a quiet, retired country village. Cats are their greatest enemies, and are alike destructive to eggs and young birds. A few weeks ago I went in the kitchen garden to an iron pump, which had not been used during the winter; before pumping I by chance lifted the top, which was not screwed down, and found a greater tit (*Parus major*) had set up house there. The whole circumference of the pump top, about 5 in. in diameter, was filled, the edge of the nest being just level with the bottom of the spout opening, and the bird went in and out by the spout. She was sitting upon five eggs, and in due time they were hatched. A few days after I saw my cat sitting on the pump stone under the spout, evidently intently watching, and my man told me it had already succeeded in getting one of the young birds out of the nest by standing on its hind legs and putting its fore-leg up the spout. I afterwards measured the distance it had to reach; from pump stone to mouth of spout, 2 ft. 1 in.; length of spout from mouth to edge of nest, 10 in.; depth of cup of nest, 2½ in. I took the cat away and shut it up (and kept it so), there being then four young healthy birds in the nest, but it was all in vain. Other cats must have found the nest and exercised their skill, for a day or two after only three birds were left, a few days later one, and then that vanished also, so that within ten or twelve days of hatching the poor tits had lost all their brood; and the case has been the same with the shrubbery nests, except that usually they have been destroyed before hatching. To find torn nests with a few fragments of egg shell has been the rule with about nine out of ten. If we depended on our gardens and shrubberies for the supply of our small birds, I think we should soon be very short of them.—E. C.

PARMENTIER.

PARMENTIER, who was born in 1737, was the introducer of the Potato into France, but after it was introduced he had great trouble in overcoming the prejudices that existed against it. Its cultivation was thought to injure the land, and its use as food to generate disease; even as late as 1814 no more disrespectful name could be applied to any one than that of Potato eater. The Academy of Besauçon having offered a prize for that esculent which would be most likely to mitigate poverty, the Potato was selected as best calculated to avert that evil. This gave Parmentier fresh courage, still he felt that nothing short of positive facts and unquestionable experience could remove

success; to Parmentier therefore is due the credit not only of introducing, but of making the Potato popular in France, where, after Corn, it forms the most useful article of food.

M. L.

Radishes in Japan.—The "Scientific Farmer" publishes a letter from President Clark, now in charge of the Japanese Agricultural College, in the course of which he makes a statement as regards the Radish which we have never seen elsewhere. It is as follows:— "It is astonishing to see how the Japanese cook a great variety of nutritious dishes without milk, butter, or fat of any sort, or even sugar. They seem to make Peas and Beans furnish their albuminoids,

Parmentier, the Introducer of the Potato into France.

the prejudice which existed against it; he therefore published an analysis of the Potato, and to prove practically with what facility Potatoes could be cultivated, he planted 54 acres with them in the plain of Sablon, just outside Paris, a plain which had always been considered sterile. When the plants flowered he presented a bouquet of the blooms to Louis XVI., who was a great lover of the Potato, and who placed the flowers in his coat, a circumstance which did more than anything else to bring the Potato into notice. Nevertheless Parmentier employed other means, with the view of making it popular, one of which was as follows:—He invited all who were of acknowledged learning or otherwise influential to a dinner composed wholly of Potatoes, which were served up in all kinds of ways, and his perseverance was at last crowned with

and Rice their amyloids. Thus you perceive they use the Simon pure, original articles. The one vegetable which serves all purposes, and seems to be absolutely indispensable to every Japanese, whether high or low, is the Radish. They have developed it to gigantic proportions; the roots being often 3 ft. long and 3 in. in diameter. The colour is always white. They eat it raw with salt; they boil and serve it as we do Turnips; they pickle it in brine, tops and roots, and consume the (to us) uninviting result in vast quantities; they dry tops and roots and feed upon them; and, worst of all, they hang them on poles in the fields to freeze and thaw all winter, and then consider the shrivelled remains worth eating. I believe the Chinese use the Radish in a similar way, and it is undoubtedly specially suited, in its taste and effects, to the wants of Rice eaters."

What the Upas tree keeps deepest hold by—the top-root.—"Punch."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Greenhouse Plants in Small Pots, that have their leaf-surface large in proportion to the amount of soil in which they are grown, will require constant attention as to water, of which a frequent supply, sufficient to saturate the whole of the soil, should be given, as they invariably suffer more from a scarcity of water than those plants whose foliage-surface is more limited.

Cinerarias and Primulas, sown some time ago, should, as soon as they are large enough to handle, be transferred to small pots, or they can be put $1\frac{1}{2}$ in. apart into large pans in fine soil made rich and loose by the addition of sifted leaf-mould and a little sand, remaining there only so long as they do not become overcrowded, after which insert them singly in 3-in. pots. Both Cinerarias and Primulas should be placed close to the glass, in an ordinary garden frame, at the north side of a wall or fence, where the sun will only reach them morning and evening; but they must have plenty of air, bearing in mind to keep always moist the bed of ashes on which they should stand. Primulas of the *Cortusoides* section, grown in pots, should be kept plunged through the summer in a bed of ashes on the north side of a wall, and well attended to with water, for, if at all neglected at this season, no subsequent attention can remedy the injury they will have sustained. *P. japonica* is not often seen in the condition in which it is capable of being produced, and through this cause has disappointed many. Instead of confining it to the small pots it is often flowered in, if the plants have more room (say 10-in. or 12-in. pots), be grown in good soil, and supplied with manure-water as often and as strong as a *Calceolaria* will bear, the appearance of both leaf and flower will be very materially improved.

Campanula pyramidalis is one of the best summer-flowering plants that amateurs can grow; they will now have made considerable progress, and will be much benefited by an application of manure water every week. Young plants raised from seed this spring should, as soon as ready, be pricked off into small pots and encouraged to make growth, for upon the strength they attain before autumn in a great measure depends their blooming capabilities during the ensuing year; when well managed they will make flower-stems 8 ft. or 10 ft. high.

Mignonette should now be sown in pots for winter flowering; this will not attain the size it would if sown a month or six weeks earlier, but for general decorative purposes it will be rather an advantage than otherwise, as a number of comparatively small plants, when well flowered, will in most cases be more useful than larger specimens. Take as many 4-in. pots as will be required, in the bottom of which put $\frac{1}{2}$ in. of drainage material, over this a little dry rotten manure, such as has been used for mulching, then fill up to within $\frac{1}{4}$ in. of the rim with good ordinary loam, to which has been added one-fifth of rotten manure and a little sand, pressing it firmly in the pots; on this sow the seeds (six or eight to each, ultimately thinning them down to half the number); place the pots as close as they will stand on a bed of ashes in a cold frame, keeping the lights off until autumn, unless the weather should be excessively wet.

Flower Garden.—Pay all requisite attention to bedding plants by giving them sufficient water as often as required, and in this way, so far as possible, endeavour to make up for the late, unsatisfactory condition they are in. In applying water in dry weather it is much better to give as much once or twice a week as will moisten the soil to a depth of 3 in. or 4 in., than to sprinkle the surface daily, which latter operation is far too generally practised, and tends to promote root-action near the top alone, leaving the lower and more important feeding fibres in almost a dormant condition.

Herbaceous Plants.—There are few hardy plants more general favourites than Pansies and Violas, especially the good old varieties of the former, with their beautiful, well-defined colours. In many of the kinds which have of late years made their appearance, and are known under the name of Fancy Pansies, the indescribable confusion in shades and colour renders them destitute of every property that constitutes a handsome flower. Instead of growing these, I should recommend amateurs to confine themselves to the purely-marked flowers, and if a small piece of ground on the north side of a wall (where the midday sun cannot reach them in sunny weather) be devoted to them, their flowers (so useful for cutting) may be had at this time, when there is much more difficulty in keeping them blooming than during the spring and later in the autumn. Another essential to secure a continuous supply of flowers is to strike plants sufficiently often; cuttings should be put in as soon as they can be obtained in the spring, again about the present time, and also in the

autumn; these should consist of young suckers that spring from the bottom and not flowering shoots, which root indifferently. They strike in a very short time if set 1 in. or 2 in. apart under hand-lights out-of-doors, kept moist, and shaded, in all stages of their growth. Pansies succeed best in moderately light soil made rich with leaf-mould, or any thoroughly decayed vegetable matter. One of the best cultivators I ever knew used to grow his in half loam added to an equal quantity of decomposed Potato haulm; in this compost they made amazing progress. For spring and autumn flowering, instead of a northern aspect they should have a more sunny position, and should never be allowed to flag for want of water, as their roots, being so near the surface, quickly get burnt up. The same treatment will in every way suit Violas, which differ but little from Pansies, only as being more floriferous, and the disposition of the best varieties to continue blooming more freely through the summer. Amateurs, who as a rule care more for a continuous moderate supply of flowers in their gardens than a bright mass for a short time with a dearth at others, will, during such seasons as the present, see the necessity of cultivating continuous-blooming subjects, such as Pansies and Violas, rather than depending too much upon ordinary bedding plants, which, even under the best management, are up to this time little more effective than if the beds had still been occupied by the small shrubs with which they are usually filled through the winter. In gardens where there are no pretensions to grow an extensive collection of herbaceous plants, but where, in addition to the above, are to be found the White Perennial Iberis, Anemones, Aquilegias, Arabis alba, Aubrietia purpurea, Daisies of kinds, Cheiranthus Marshalli, Dielytra spectabilis, Dodecatheons, Gentiana acaulis, Myosotis, Pentstemons, Primulas, Wallflowers, spring-flowering bulbs, &c., will have prevented the barren appearance that exists where but little besides summer bedding plants are cultivated. Should the present dry weather continue, where spring bedding plants are used to a considerable extent and now transferred to the reserve ground, they must be well attended to with water, as from their recent removal the roots will not yet have got full hold of the fresh soil; without sufficient moisture to sustain them they will make little progress through the summer, and upon this in a great measure depends their ability to bloom well in the beds assigned to them during the spring.

Walks.—Where salting walks for the destruction of weeds is resorted to, dry weather is much the best in which to apply it, salt dissolved in water is the most approved method, but it should be as near boiling heat as possible. There is one objection to salting walks, viz., that it gives to most kinds of gravel a dark, damp appearance; and if the value of the salt thus used were spent in labour in hand-picking before the weeds became numerous and were allowed to seed, it would be found the most economical. Through the difficulty of extracting weeds from a gravel walk when dry and hard, they are often allowed to remain until moistened by rain, during which time they may be maturing and scattering seeds by the thousand, whereas if a few pots of water be poured on with a rose-spouted can, a considerable space may be thus moistened in a very short time, and the work of weeding greatly facilitated, as a man will do as much in one hour with the walk in a moist condition as he will in three when dry.

Kitchen Garden.—Through the scarcity of Apples this spring, there has, in the London and other markets, been an extraordinary demand for Rhubarb, which has consequently realized a very high price, and from the same cause there is every likelihood of a recurrence of this state of things next spring. The yield of this useful plant is always proportionate to the strength of the roots; nothing tends to weaken them so much as long and continuous gathering, whereby the quantity of leaves left to grow to maturity and die off naturally in the autumn are not sufficient to recuperate the roots for the loss they have sustained by the great demand thereby made upon them. I should recommend that from this time but little should be gathered, and the beds should be assisted by manurial stimulants of such a character that will be quick in their effects, such as a copious application of manure-water made from stable manure, or failing this, guano, to which has been added a little soot, may be used at the rate of a handful to about 6 gallons of water, keeping it away from the leaves and crowns of the plants. If after this the ground be mulched with some littersy manure, it will be an advantage. The result of this will be found to well repay the little trouble involved.

Great Height of Australian Gum Trees.—"While the *Eucalyptus amygdalina* attains a height of from 473 ft. to 496 ft., the dome of the Invalides at Paris is only 343 ft. high, the Cathedral at Strasburg 462 ft., and the Pyramid of Cheops—the highest building in the world—476 ft. The *Eucalyptus globulus*, although not attaining to the height of the *E. amygdalina*, is still taller than the celebrated California tree, the *Wellingtonia*.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

July 2.—Potting *Thyrsacanthus*, *Poinsettias*, double Wall flowers, and *Amarantus*. Shifting *Odontoglossum Alexandræ* and *Masdevallia Harryana* into larger pots. Planting verandah boxes with Stocks. Putting out main crop of Celery, Chilies, and Chervil. Putting in cuttings of *Poinsettias*, staking Carantions, and removing superfluous shoots from espalier Pear trees. Earthing-up Brussels Sprouts. Cleaning walks, and plunging East Lothian Stocks in cold frames. Distilling Roses.

July 3.—Potting Victoria Stocks, and putting winter Carantions into their flowering pots. Sowing Campanula seeds, Parsley, and Intermediate Stocks. Planting May-sown Lettuce and Snow's White Broccoli. Putting *Heliotropes* cuttings to make plants for winter-flowering. Digging land for late Peas and Broccoli. Putting *Amaryllis* in sun to ripen their bulbs. Exposing ripening Peaches in late house.

July 4.—Repotting *Odontoglossum vexillarium* and *O. Roezli* in Moss and crocks, and top-dressing them with peat and sand. Planting Veitch's Autumn Giant Cauliflower and Savoys. Taking up Hyacinth bulbs and drying and storing them. Nailing in Peach, Plum, and Pear tree shoots. Thinning Turnips, and digging land for Early Horn Carrots.

July 5.—Planting Vegetable Marrows in frames lately cleared of Carrots; also more Celery. Washing *Lycastes* and other Orchids infested with thrips with Tobacco-water. Hoeing among all growing crops, and digging all vacant land.

July 6.—Potting *Selaginellas* for conservatory decoration, and putting young Vines into 10-in. pots. Planting a border with Ten-week Stocks and Asters. Looking over Gooseberry bushes and destroying caterpillars. Putting all spring-flowering bulbs that are dried off into hampers and storing them away in a cool place. Hoeing among Onions, Carrots, and Beetroots.

July 7.—Putting *Chrysanthemums* into their flowering pots, and potting young *Heliotropes* and scarlet *Pelargoniums*. Shifting *Odontoglossum cariniferum* into larger pots; also lately-imported Orchids. Shifting Canterbury Bells and Intermediate Stocks; also Red Globe Turnips.

Hardy Flowers.

HARDY ANNUALS.—We have early summer and midsummer blooming annuals, but a great many of the earliest are so late this season that the chief display of bloom will be in July. Annuals are looked upon as common flowers, but at best they are but imperfectly known. If evidence of this were needed, it could be found in lists of kinds frequently recommended for cultivation, which invariably include some that are scarcely worth growing, and omit others that are really valuable. Provided the soil be warm and light, and the situation dry, there are some annuals that should be sown in autumn, as, unless the winter prove wet and severe, they root better, make a more profuse growth, and flower earlier than if sown in spring. Among those which may be sown in autumn may be mentioned *Nemophilas*, Sweet Peas, Candytufts, *Eschscholtzias*, Sweet Alyssum, *Virginian Stock*, and *Limnanthes Douglasi* and *grandiflora*. The following are the names of some of the choicer kinds of hardy annuals that well deserve a place in gardens, viz., *Calendula pluvialis*, a kind with large, star-like, white flowers, having a dark centre, dwarf, and very free; *C. Pongei*, a double form of this, lasting a long time in bloom, and very like a white *Chrysanthemum*, but lacking the perfect arrangement of the petals; *Centaurea (Cyanus) depressa*, a sort with large, showy, rich, pale blue flowers, very striking at this season of the year, and most useful to cut from; *Calendrinia speciosa*, pretty rose; *Collinsia bicolor*; *C. multicolor*, a purple form of *C. bicolor*, and very good; *Gilia laciniata*, purplish-mauve, the flowers borne in dense clusters, a capital plant to cut from; *G. achilleifolia*, purple, very good; *G. tricolor*, effective; *Helenium Douglasi*, silvery foliage, large green flowers with orange centre, very effective; *Linaria bipartita*, white margined with purple, very pretty, and remarkably free, growing from 12 in. to 15 in. in height; *L. spartea*, very bright orange and yellow, highly effective; *Leptosiphon androsæous*, in variety, which includes several very pretty colours, such as white, cream, lemon, rose, and purple; *Lasthenia californica*, one of the most effective of the yellow flowering spring annuals, the flowers golden yellow with an orange centre, very dwarf, free, and effective, especially at a distance; *Loasa tricolor*, orange and red, dwarf, bushy growth, very good; *Nemophila insignis*; *N. maculata*,

the flowers white spotted with purple, large and showy; *N. discoidalis* and its varieties are interesting, but they lack the fine bold form of *N. insignis*; *Oenothera Bistorta Veitchi*, with pure yellow flowers on a dwarf growth, very free and effective; *Schizanthus pinnatus*, very handsome, with dark blotches on the upper petals; *S. gracilis*, a slender growing form, the flowers pale purple with dark markings; *S. pinnatus vigrioides*, the upper segments flaked black on a golden ground, very pretty indeed; *Silene rubella*, dark magenta, very pretty; *S. Pseudo-Atocion*, bright pinkish rose, very bright and effective; and *S. Saponaria*, a very attractive pink, like a large-flowered *Saponaria calabrica*; *Veronica syriaca*, pretty bright blue, might be very effectively grown in pots for spring work; and the white and red *Valerians*, both of which are valuable to cut from just now. This may appear a long list, but it is a select one, and it represents the very best annuals in bloom in the middle of June.

AQUILEGIAS.—I have this season bloomed in my little front garden, open to a public road, the neat *Aquilegia cœrulea*, and it has been generally admired. A few days ago an opportunity was afforded me of inspecting a large bed of double varieties, some of which were extremely pretty. Seed of good strains of double *Aquilegias* can be had at a reasonable price, and it would be difficult to name another border flower that has a greater interest for lovers of what might be called homely gardening. If the seed be sown in a prepared bed on a shady border, or in a shallow box in a cold frame, the plants, if properly cared for, will by the end of the summer have grown sufficiently large to plant out to flower. This is just what has been done in the case of the plants in question. They had great varieties of colour—blue, mauve, rose, lilac, creamy-white, &c., and some of the striped forms were admirable—one in particular had the white corolla handsomely flaked and striped with blue, and it had appeared both in a double and single form.

LUPINUS.—Of these there are some very beautiful annual varieties, to which it will be necessary to call attention later in the season. Just now some of the beautiful perennial kinds are in bloom and very fine; they are for border work, among them *Lupinus magnificus*, purple; *L. polyphyllus*, purplish-blue; *L. polyphyllus albus*, white; *L. elegans*, purple, very good; and *L. arboreus*, lilac. Seeds of these can be obtained, and if sown at once in a prepared bed, good plants would be ready to plant out at the end of the summer, to flower in May and June next. They are indispensable to the mixed border.

D.

TREES AND FLOWERS.

AMONG the chief silent friends, comforters, and cheerers of man are trees and flowers. I have sometimes asked myself, which gave me the more pleasure? Perhaps a reader will answer readily, "flowers." But think a moment! Time and continuity are great tests of friendship, and these test trees will bear; for although flowers soon wither, die down, perish, trees are more constant; they abide by us always; they are neighbours, I might almost say, for ever. Not only are trees with us in leafy June, one of the most enjoyable months of all the year, in their bright green splendour, but when autumn comes there they still are, clad in another garb of beauty more gorgeous, though not so glad some; and even in winter who would wish to be without their tree neighbours? The perfect symmetry of a tree is never better seen than in winter, and the dullest eye and heart recognize their vernal beauty. There are trees too which openly show no change in their leaves, and so gladden us all along the dreary season by their greenness. Moreover, in those that shed their leafy garb, see the fantastic forms of beauty which they become when decked by a hoar frost or a snow-storm, especially by the former. I would say that nothing takes off the dreary feeling of winter so much as the presence around us of finely grown trees. When all that out-of-doors formerly cheered us is gone, when flowers, corn-fields, and green Grass are no more, when hedges have become mere dark lines or intersected branchlets, yet the trees are there around us still, and present with us to comfort us. Perhaps no one can so thoroughly appreciate the value of fruit trees as one horn, or having lived many years among them. The treeless plains, like prairies, are akin to the ocean's calm, and on them companionship seems lost. We read of one, when the architect wished to cut away a noble old tree, who said, "No! move the house, but you cannot grow such a tree in my life-time. Oh! the hours of pleasure I have taken under its shade, and the sweet memories of youth and its associates they bring are beyond all of art's splendours." Trees vary indeed, according to season, but each variation is a separate beauty; bud, leaf, lighter at first, then darker; then come the rich, autumnal tints, and then the grand visible branches stretching far and wide during the winter months—long, low-hanging limbs; and when the heavy frosts come the whole tree is standing jewel-decked.—T. R. ELLIOT, in "Prairie Farmer."

ARECA PURPUREA.

THE ARECAS constitute a well-known section of the Palm tribe. A Catechu is a handsome tree, cultivated in all the warmer parts of Asia for the sake of its fruits, which are of the size of a hen's egg, of a reddish-yellow colour, and with a thick fibrous rind, within which is the seed; this is known under the name of the Areca Nut, Penang, and Betel Nut, and is about the size of a Nutmeg, but conical in shape, flattened at the base, brownish externally, and mottled internally like a Nutmeg. These Nuts are cut into narrow pieces, which are rolled up with a little lime in leaves of the Betel Pepper. The pellet is chewed, and is hot and acrid, but possesses aromatic and astringent properties. A sort of Catechu is furnished by boiling down the seeds of this Palm to the consistency of an

EFFECT OF COLOURED LIGHT ON PLANTS.

A CORRESPONDENT of the "Globe," Toronto, gives the result of some experiments in 1876, showing the effects of coloured light on plants, as follows:—I planted in a box some Curled Cress seed, and so arranged bottles of carmine fluid, chromate of potassa, acetate of copper, and sulphate of ammonia, that all but a small space of earth was exposed to light, which had permeated three-fourths of an inch of these media. For some days the only apparent difference was that the earth continued damp under the green and blue fluids, whereas it dried rapidly under the red and yellow. The plumula burst the cuticle in the blue and green lights before any change was evident in the other parts. After ten days under the blue fluid, there was a crop of Cress of as bright a green as any which grew in

Areca purpurea.

extract; but the greatest quantity of the drug called Catechu used in this country is the produce of *Acacia Catechu*. In Malabar another species, *A. Dicksoni*, is found wild, and furnishes a substitute for the true Betel Nut to the poorer classes. *A. oleracea* is the Cabbage Palm, which is found in abundance in the West Indies. It derives its name from the bud which terminates its lofty stem. This bud consists of a great number of leaves densely packed; the inner ones are of a white colour and delicate flavour, and serve as a vegetable. *A. purpurea*, the species represented by the accompanying woodcut, has recently been brought into notice by Mr. Williams, of Holloway. As will be seen, it is an extremely graceful kind, especially in a young state, and one which well deserves attention.

The largest Pine tree in Northern Wisconsin. — This is said to be in Wood County. At 3 ft. from the ground it measures 20 ft. 6 in. in circumference, and it is 70 ft. from the ground to the first branches.

full light, and far more abundant. The crop was scant under the green fluid, and of a pale, unhealthy colour. Under the yellow solution but two or three plants appeared, yet they were less pale than those which had grown in green light. Beneath the red bottle the number of plants which grew was also small, although rather more than in the spot the yellow covered. They, too, were of an unhealthy colour. I now reversed the order of the bottles, fixing the red in the place of the blue, and the yellow in that of the green. After a few days' exposure the healthy Cress appeared blighted, while a few more unhealthy plants began to show themselves from the influence of the blue rays in the spot originally subjected to the red. It is evident from this that the red and yellow rays not merely retard germination, but positively destroy the vital principle in the seed; prolonged exposure uncovered, with genial warmth, free air, and, indeed, all that can induce growth, fails to revive the blighted vegetation. I repeated the experiments many times, varying the

fluids, but the results have been the same. I have the above facts strikingly exemplified where the space covered by the bichromate of potassa is without a plant.

TAR PAVEMENTS.*

To many the construction of tar pavements is a familiar work, but there are others perhaps who have not as yet tested their suitability for suburban paths. In some counties, such as Lancashire and Yorkshire, tar pavement is not a matter that would receive much attention; but in the eastern counties, and other districts not favoured in the same way, and where stone pavements cost seven times as much as tar pavements, the latter is of some importance to towns requiring a clean and economical footway. In Ipswich the mileage of footways in proportion to the population is very large, the population being 46,000, the distance of streets and roads being about 75 miles. Of this about 22 miles are town streets, and double this distance would represent about the length of paths. Formerly all the suburban paths, as well as the majority of those in third-rate streets, were made with gravel. These, however, were always in a defective state. To prevent mud accumulating in winter, shingle was put on the surface. This shingle in summer time was disintegrated, and laid on the surface as though it had been strewn with Peas or Beans. To avoid this, loamy gravel was put on. Then, again, in winter this worked up into mud, and again had to be covered with shingle, and so on alternately winter and summer. The defects gave rise to continuous complaints, and having had experience of tar pavement in other towns, I was induced to recommend it as a substitute for gravel. My suggestion was approved by the authorities, and specimens of the pavement were laid, the first being done by contract at 1s. 3d. per superficial yard and maintained in repair for five years. This was thought to be too much, and the sanitary authorities decided to make their own. I have prepared the material in different ways, sometimes using simply pure coal tar; at others, refined tar; and occasionally, small portions of pitch, lias lime, and Portland cement in the preparation of it. But in practice (although I use mainly refined tar) coal tar is all that is required, and will make as good a path as refined tar, or any other admixture. I have two ways of making tar pavements in this borough. One is with shingle—that is, fine gravel; and the other with slag, which is clinkers and refuse cinder dirt from factory furnaces. The process of making with shingle is simple, and is as follows:—A fire is made on the ground and covered over with shingle; when this first covering is heated through more is added from time to time until there are about 10 or 15 tons. For convenience in sifting over the stuff after it has been heated through, it is desirable that the fire should be of an oblong shape, presenting a form something like the mounds under which Potatoes or Mangolds are stored in a field. After the whole has been sufficiently heated to take out the natural moisture, it is sifted, the fine being placed in one heap and the coarse in another; when about one barrowload of each has been sifted, boiling tar is thrown upon each of them while in a hot state: the whole is then turned over with shovels and thoroughly mixed. The coarse forms the bottom layer of the path, and the fine the top surface. After a path has been made about ten days it is dressed over the surface with boiling tar and sharp sand or ashes left from the heap of stones after burning. The sand combines with the tar and fills up the small interstices and produces a smooth surface. In making those pavements from slag it is not necessary either to heat the material or boil the tar. The material collected is turned over so that all the large clinkers are broken into small pieces, after which the whole is sifted over to separate the large from the small, and is then mixed with cold tar (unless the weather is very cold, when it is warmed to make it mix more readily). The material made in this way is laid down in the same manner as described for shingle, but is not dressed on the surface with boiling tar and sand, being better without, but it is covered with a copious sprinkling of white Derbyshire spar, which is well rolled into

the top layer to relieve the dull sombre appearance and give it a pleasing effect. In laying the paths care should be taken to roll the ground well, and bring it to a uniform surface before the bottom layer is laid on, to avoid uneven or soft places, which, if not provided against, would result in the path, after being down for a time, having a series of undulations on the surface; in laying each layer should be well rolled with a roller weighing about 7 cwt. The bottom layer should be 1½ in. thick, and the top one 1 in. It is advisable to keep the prepared stuff a few weeks before it is laid down, and although the work can be done in almost any season, spring and autumn are the most suitable, when it is dry and not too hot. Shingle tar pavements require dressing over with boiling tar and covering with sharp sand from time to time to preserve the surface, which, if not dealt with in this way, would become rough by reason of the softer material wearing from between the joints of the stones. The material does not always turn out equally well; sometimes a path will not consolidate, and at another time the surface will break up without any, as far as can be seen, apparent reason. The shingle tar pavement costs 9d. per superficial yard laid complete, and that made from slag, 11½d. Preference is given here to those made of slag, but are more costly in the first instance and less durable than those made with shingle, which can easily be understood when the nature of the material is considered; in the first instance we used shingle entirely, but from favourable reports of the Sheffield paths, and from a personal examination, and from the easier mode of preparation, I was induced to adopt that plan. I believe the Sheffield paths are better than those in this town, and I have no doubt it arises from the fact that the material is of a more durable character that can be procured in Ipswich. The cost of these pavements varies according to local circumstances, being as low, in the case of Sheffield, as 7d. per yard, and as high in London as 2s. 3d. From information obtained some time since I found that the general price of this kind of pavements was about 1s. per yard, exclusive of the cost of preparing the foundation. The price I have given for Ipswich paths includes the foundation. Tar pavements are generally adopted as an improvement on gravel paths, and are not supposed to be regarded as a material to be taken in comparison with asphalt, although I think they bear favourable comparison to many of the more costly pavements, and are, in my opinion, much to be preferred to the common asphalt prepared from pitch, to say nothing of the difference of cost, and which expands and contracts with variations of temperature. I have tried other materials for making cheap pavements for footways, such as bricks, earthenware tiles, and Portland cement concrete, but the cost, which is about 4s. 6d. per superficial yard, precludes their use for suburban paths, and their durability is not sufficient to allow them to be put in the place of York flagging for main streets. A path made from shingle, and repaired in the way I have described, would last, with the ordinary traffic of a provincial town, ten years. Paths laid under my directions as long since as this are still in fair condition. It is, however, difficult to say what the life of pavement would be without very careful observations extending over a considerable period, as the duration of any paved footway is simply determinable by the amount of traffic. Having regard to the economy of first construction, reduction of dust and scavenging, and the cleanliness of the path after rain, it appears to the writer that there is no better material for suburban footways than tar pavement. It may be objected that the dull appearance, the difficulty of repairing them so as to bring the repaired part even with the old, and the disturbance of the path caused by laying on gas and water, are against their adoption. The first objection can be avoided by using a good covering of Derbyshire spar, and the second applies, more or less, to any pavement, with the exception of York flagging. When I commenced to lay these paths ten years ago, they were rather scarce, and had only been laid to a limited extent in a few towns, but during the last five years they have been very largely extended, and will in future occupy a permanent position among other paving materials for constructing footways in towns; this shows the suitability of the material for such footways as I have referred to in this paper. There are now about 15 miles of these paths in Ipswich, taking the place

* Paper read by Mr. E. Buckham, C.E., at the meeting of the Eastern Counties District Association of Municipal and Sanitary Engineers and Surveyors, which took place the other day at Ipswich

of paths which would, if they had not been superseded with this material, have still been muddy in the winter, and so rough on the surface in summer as to make them always, more or less, unpleasant to walk upon, to say nothing of the indirect discomfort to the inhabitants by reason of the additional dirt in winter and dust in summer. The cost of paving this length of footways with other material would have been so considerable as to have prevented the possibility of doing it, and I look upon it as a great boon to the inhabitants of any town to get such good pavements for suburban paths at such a small cost.

Discussion.

Mr. Flintham said the paper fully bore out his opinion of the practicability of tar paths. The older the material was the better it was for use. It should not be used before it was three months old. In Aldeburgh they put gravel at the bottom and cinders at the top, which they found answered admirably. The spar was also put on more liberally than it had been in Ipswich.

Mr. Baker said his experience was that tar paths stood the wear and tear of traffic very well indeed. It was extensively used at railway stations for platforms, and that was a very good test as to its suitability. In Yarmouth they were using concrete largely, but the great objection to that was its expense.

Mr. Lobley had had no experience in laying tar paths. In Hanley they used blue bricks at a cost of 2s. 8d. per square yard. It would cost rather more than that in Ipswich, as the bricks would have to be carted further. The brick pavements would last forty years, and he made the suggestion that they would in the end prove less expensive than tar paths. He was going to try tar to test that point.

Mr. Ellice-Clarke was much obliged to Mr. Buckham for bringing the question of pavements forward. He was in favour of tar over gravel paths, but even at the low cost mentioned by Mr. Buckham, he did not know that they were the cheapest. He thought concrete pavement in bricks was more economical. He produced a piece taken from a street in Brighton which had been down twenty-five years in a thoroughfare where there were 1,500 passengers daily. It was originally 2½ in. thick, and had not appreciably worn—it had not worn one-eighth of an inch over the entire surface. It cost at the time it was laid 3s. 4d. per yard. In Folkestone they had abandoned tar for concrete, the cost of which was 2s. 4d. per yard. The Yorkshire stone pavements in Brighton had cost 9s. 9d. per yard, and had worn 100 per cent. more than the concrete. In making concrete blocks sea-water was used, which added materially to the strength. The cost of blue bricks was quite as much as the Yorkshire, and they were very slippery. The only asphalt to compare with concrete or York stone was the Val de Travers compressed asphalt.

Mr. Ditcham said some tar paths had lately been laid in Harwich at a cost of 11½d. per yard. They were made with cinder instead of shingle. The Caithness flagging had been tried, and wore very well indeed.

Mr. Hope pointed out that tar paths were not suitable for the south side of the streets on account of the heat in summer. At Scarborough they went to great expense in the matter, but in summer the tar paths were almost like sponge. The cost of carriage of blue bricks was very much against their introduction. In durability they answered very well indeed.

Mr. Inch said he had used some concrete at Lowestoft, and at present it wore well. The only objection against that or tar was the patchy appearance it had when broken up for gas or water pipes.

Mr. Goddard did not think that if the tar pavement was properly mixed it would become soft in hot weather. For suburban paths there was nothing so pleasant to walk upon, and when sparred they looked very nice. There was not much breaking up in the suburbs for pipes, and therefore the objection to the patchy appearance did not hold so strongly. In answer to Mr. Buckham, as to the better kind of tar to use, he was in favour of the adoption of refined in preference to the coal tar. It made a more solid path than the coal tar.

Mr. Wiggin thought the difference between the tars was a question of degree. He questioned whether pitch was not the better article.

Mr. Goddard said there were two difficulties—it was either too soft or too hard. It was, therefore, better to mix it with creosote, or any heavy oil.

The President said everything depended on the way in which the path was made. Mr. Goddard had laid a small sample in Winchester, and it had worn very well, but had not yet been adopted. It was a good substitute in suburban districts for gravel paths, and when that was said, he had said all. As regards flagging, he was in favour of Caithness.

Mr. Buckham agreed with keeping the material a little time before using it. As to bricks, his experience was not at all satisfactory, as the surface wore off and left a soft material. If he used bricks at all, he should use brimstone lumps, and he recommended them very highly where any one desired to use bricks. They would cost 4s. 6d. per yard to lay in Ipswich. The great advantage of tar paths was the smallness of the first cost.

WATER-CRESS.

IN these sultry summer days we should be all much cooler, and many of us infinitely more comfortable, did we eat less butcher's meat. Often for weeks at a time we really "enjoy," after a fashion, a tropical climate without any of the conveniences for keeping cool that dwellers in the sun-lands usually provide. We should, for instance, take more vegetable food, and, above all, more of those cooling salads which are at once so cheap and so wholesome. The simplest and most popular is probably the ordinary Water-cress. Extensively as it is used in London, in Paris, and other continental cities, it is not only eaten raw, but largely consumed as an adjunct to many *plats*. No less than thirty waggonloads of Water-cresses, each worth £12 sterling, daily pass the barrier of Paris, thus showing that the French capital expends on this ditch weed not less than £360 per diem. The Water-cress is one of the oldest known esculent plants. It is said to have been eaten by the ancients along with Lettuces to "counteract the coldness" of the latter by their stimulating qualities. Be that as it may, we know that there is no more powerful anti-scorbutic than the common Water-cress of our ditches. It is said that Nicholas Meissner, of Erfurt, about the middle of the sixteenth century, made the first effort at cultivating Cresses artificially, and to this day Erfurt is celebrated for its "Kresse," most of the Rhine towns, as well as Berlin, 120 miles distant, being supplied with them. In the neighbourhood of London, Water-cress culture was first commenced at Northfleet, not far from Gravesend, and is now carried on in many other localities, particularly near Rickmansworth in Hertfordshire, Waltham Abbey in Essex, and Uxbridge in Middlesex. Even the many acres of the plant cultivated can barely supply the demands of the London markets. How much is now consumed in the metropolis is not accurately known; but Mr. Horace Mayhew calculated that 14,958,000 bunches were sold in the course of 1851. Of this amount the street sellers alone disposed of £13,949 worth. The Cress for sale in Farringdon Street Market was at that date coarse, but ten times more of it was sold than the finer kinds offered in Covent Garden. Five hundred families—or, at least, 1,000 persons—supported themselves by selling Cress in the London streets. On an average they disposed of 5s. 6d. worth per week each, on which the profit was 3s. 6d. per individual. This estimate of the Cress trade in London does not, of course, take into account the amount brought in directly from the country and disposed of by street hawkers or to the greengrocers. It is only the costermonger's share in it that is spoken of. As the population of London has so vastly multiplied in 26 years, the amount now consumed must be much greater, and is likely to increase, as the doctors have now discovered that in addition to being a wholesome salad, Water-cress is a valuable remedial agent in some forms of febrile diseases.—"Echo."

Transit of Plants by Post.—Persons residing in the country should take advantage of the parcel-post system. A few weeks ago I received a small parcel from London containing 15 lb. of Potatoes of the new exhibition kinds; the carriage to North Yorkshire per rail was 4s. A few days afterwards I received two parcels by post containing thirty-six bedding Geraniums, fifty Lobelias, fifty golden Pyrethrams, and thirty-six *Perilla nankinensis*, the postage of which was 7d. The advantage and convenience of the postal system to amateurs are very great, especially to those residing in the country, because the plants are brought to their doors along with their letters. The plants do not suffer so much as those sent by railway, which are sometimes a whole week in arriving at their destination, besides the trouble of sending for them to some distant railway station. Plants packed in a little Moss and placed in strong pasteboard boxes arrive in fine condition.—H. TAYLOR, in "Gardeners' Magazine."

Double Scarlet Geum.—This fine plant deserves a more conspicuous notice than the brief reference made to it in your last week's number. If it were characterised as one of the very best of the early-blooming hardy perennials, its merits would not be at all exaggerated. The flowers are very large, of a deep scarlet, verging on crimson, and like most double and semi-double flowers, it retains its petals longer than the single form. A mass of it is most effective, and as it is one of the easiest of plants to cultivate, and comes true from seed, it is within everybody's reach.—W. THOMSON, Ipswich.

PERENNIALS FOR BEDS.

THE secret of the success of the bedding system, now so much in vogue, lies in the fact that a good-sized mass of any one given plant when in flower is far more striking and effective than is a single plant of the same variety. Of course, this is a mere truism, but it is one not sufficiently considered in garden arrangements, and too often the splitting up of quantities into units, has had as a result that nothing is left worthy of notice. It is thus, that because we grow so many of our hardy perennials rather as border curiosities than as decorative plants, we find them passing out of popular favour. A blazing scarlet Pelargonium or yellow Calceolaria would naturally prove more attractive with the masses than any single plant of Aquilegia, Delphinium, Rocket, or other good border perennial. We want a public garden devoted to the cultivation of hardy perennials and biennials in masses, both as a means of educating people unacquainted with hardy plants and illustrating their value for bedding purposes. We do not want bedding perennials, we rather want beds of perennials, which is a vastly different thing, and likely to be productive of more useful results. It is to be regretted that the series of beds on either side of the broad walk at Kew should be devoted to the growth in summer of a few kinds of tawdry bedding plants, whilst each bed might at some time or other be rich with the abundant blossoms of some noble perennial. In the same way, what a means of showing the public the various beauties and characteristics of good hardy plants is lost by the plan on which the long series of beds that run from the Marble Arch to Hyde Park Corner is managed! To many it is but a question of taste, and as it is evidently the object of the authorities to pay deference only to what a flower-loving but untaught public may prefer, there is little prospect of the present routine system of summer bedding being given up, even though the mountain has to labour during eight months of the year to bring forth the small display seen during the remaining four. Cultivators do not care to bed out perennials, because they cannot work out designs or secure a continuous bloom with them, but the object of growing perennials and biennials rather should be not to secure the coveted uniformity, but to obtain good showy masses of each kind in its proper season. In many instances one variety of the same family might be used to edge another, and selections of the most favoured of hardy perennials might be made. A couple of hundred beds bordering a broad walk, containing at least some 300 or more of fine kinds of hardy plants, would be indeed a glorious sight, and with a good representative selection would furnish beds in bloom in unbroken succession from March to November, nay, by means of Hellebores, Anemones, &c., the bloom might begin in January, and thus keep something in flower almost all the year through. Large numbers of people are familiar with many hardy plants only by name; they read that such things are in flower at Tooting or Tottenham, or elsewhere, but these places are to them practically inaccessible. In all the public parks and gardens, bedding, as the fashion goes, is continually duplicated, until the reduplication breeds satiety. Cannot one public place be devoted to hardy plants as a means of educating the people, whilst all the bedding-out traditions of the past are boldly thrown to the winds?—A. D.

CULTIVATION OF TREES IN TOWNS.

At a recent meeting of the Manchester Field Naturalists' and Archaeologists' Society at Handforth, a paper was read by Mr. Alcock on Trees in Towns. Mr. Alcock, who has paid special attention to the subject for a number of years past, and made many experiments in planting trees in close proximity to his mill, situated in the outskirts of the town of Bury, said that the tendency to attribute every failure in plant cultivation in towns to smoke involves a fallacy that wants guarding against. The Rhododendron, for instance, grows very well in his neighbourhood, even in the most smoky situations, and without any particular care being taken about the soil in which it is planted, though no doubt care in this respect repays the cultivator. On the other hand, the Rhododendron will not grow at all at Evesham, in Worcestershire, where the atmosphere is so pure and the climate so genial that the place has been called the garden of England. Again, the Plane (*Platanus orientalis*) has been represented as a good tree for towns because it flourishes in Paris and London. But the latitude, rainfall, soil, and subsoil of Manchester are different from those of Paris and London, while the smoke and noxious vapours in London are as nothing compared with what they are in Manchester. Mr. Alcock has planted six trees of *Platanus orientalis*, and they will not grow at all. The different sorts of Poplars have also been recommended. Experience at Bury has shown that they make very rapid growth at first, and then die. Mr. Alcock stated that he had at present a couple of Black Italians, a Balsam, and four or five Abeles, which have all been planted within the last

six years, and look healthy enough; but he knows from experience that they will shortly die, as he had already eradicated about two score of them. At Gatley, which is about the same distance from Manchester on one side that Bury is on the other, the Poplar in all its varieties grows well, but the climate is quite different, and the flora on the Gatley side of the city altogether more rich. The state of Mr. Alcock's Limes indicates perfect health, notwithstanding the unfortunate circumstances in which they are placed. Up the Rhine this tree is cut, twisted, trained, and tortured in every possible manner to form covered ways, and yet it lives and flourishes. The Lime will stand smoke, and will grow in Manchester if it be properly planted, as will also the Wych Elm, Sycamore, Birch, Horse Chestnut, and Turkey Oak. He has grown three or four plants of the Ash for about four years, and they seem to do well. The Beech grows well; he has not lost a single tree during the last twenty-five years.

INTERPRETATION OF VARYING FORMS.

MR. MEEHAN said that Mr. W. Bartram, in the last century, had found forms of *Liriodendron tulipifera* on the Schuykill River, as he had been informed by his son-in-law, with entire leaves, but only this year had he succeeded in discovering them: some of these leaves he exhibited. He observed that years ago, such discoveries had an interest in themselves. Now the botanist expected to find entire-leaved forms among kinds usually lobed, or lobed ones among the entire-leaved class; the only value now in these discoveries is in any lesson they might teach. As a rule, he hesitated to refer to the unpublished observations of others, preferring that the discoverers should, in their own good time and way, report what they had found; but hoped to be pardoned on this occasion, for saying that on a recent visit to the Academy, Dr. Engelmann had pointed out that some Oaks had lobed leaves even in early infancy, while others had entire leaves, but that those which had the early-lobed leaves assumed more entire leaves when mature, and those which had entire leaves when young, had lobed leaves when fully grown. In many Oaks which he had examined he found Dr. Engelmann's observation correct, and that it extended to many other plants. Mulberries generally had lobed leaves in their younger years, but when mature the leaves were uniformly entire; and this was especially well known in the case of the *Broussonetia*. In young Japan Honeysuckles the leaves were querciform or variously lobed, while at maturity the tendency to union was often remarkable. In the common Ivy the half-entire leaves of the young plants always gave place to lobeless forms when of fruiting age; but it was in cruciferous plants that the differences were best seen. Here lyrate or pinnatifid leaves in infancy often gave place to entire ones as the plants grew, while there were numberless instances in which entire juvenescent leaves gave place to pinnatifid ones in adolescence. However, the point was, that there was often a vast difference between the leaves of a plant's early life, and their form in advanced age. In Conifers he said this was well known. During the first few months from seed, the different species in their several sub-divisions were so nearly alike, that it was almost impossible to tell any one apart till a little age had brought divergence from the original type. He exhibited some young Thujas to illustrate this; the early Thujas all had ericoid leaves. In the forms which we knew as *Arbor-vitæ*, the condition with which we were familiar was the secondary form. In these, the leaves, which in juvenescence were free and heath-like, had become almost wholly united with branches. But there were cases where the young *Arbor-vitæ* had never had power to leave their early condition. Of this class were many so-called *Retinosporas*, *Biota Mendensis*, and many Junipers and Thujas. He had known the Thuja ericoides of gardens remain fifteen years in this infantile state, and then only one of thousands to regain the pure adolescent or fan-like *Arbor-vitæ* form. In all these cases it is important to notice that a comparative feebleness of growth, and an absence more or less total of all disposition to produce flowers, go with these continuously juvenescent characters. With the appearance of sexual characters, there is a change of form, and, in proportion as this change is the more marked, is the relative productiveness. The White Oak (*Quercus alba*) which, during its first year has entire leaves, has them lobed at maturity, and the trees which have them the most deeply lobed are the most productive in Acorns.

He found these observations to hold good in the entire-leaved *Liriodendron*. During the first year all Tulip trees had entire leaves, or at least more or less so in comparison with those which they afterwards assume. These large trees with entire leaves had merely retained their juvenescent form; the other attendant characters of juvenescence were also present. The tree from which the large, entire leaf exhibited was taken had no signs of ever having borne seeds. In one place he found two trees which, from surrounding

circumstances, he should judge were probably about the same age, and in every circumstance relating to nutrition equally favoured: one with very deeply cut leaves even to the most feeble branch was covered with seed cones, and was 13 ft. in circumference; the other had leaves almost entire, with but few fruit, and a trunk of only 8 ft. round. The danger was that in discussing laws of variation in connection with the origin of species, we may overlook the sexual and physiological changes.—“Proceedings of the American Academy of Sciences.”

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE ROSE SHOW.

JUNE 23.

THIS exhibition was largely attended—indeed crowded—during the early part of the afternoon. Cut Roses were shown in excellent condition considering the earliness of the season, but as regards numbers, they were by no means so large as usual, and the majority of the best blooms had evidently been produced under glass. In the nurserymen's class for seventy-two blooms, Mr. May, Hope Nurseries, Bedale, who was first, exhibited fine examples of the Tea-scented Madame Villermoz, large and well-coloured blossoms of Charles Lefebvre, Marie Sisley, Monsieur Etienne Levet, Louise Peyronny, and Black Prince. In the same class Messrs. Paul & Sons, Cheshunt, staged some fresh-looking blooms, amongst which were noticeable bright blooms of Duke of Edinburgh, Brightness of Cheshunt, Madame Vidot, François Michelon, and large flowers of Paul Neron. Mr. Charles Turner, Slough, staged the best forty-eight trusses of three blooms each; they comprised Madame Thérèse Levet, Duke of Edinburgh, La Rosière, and very large, richly-coloured trusses of Maréchal Niel, and Cheshunt Hybrid. Messrs Paul, too, had charming blooms of Madame Lacharme, Jean Cherpia, and Victor Verdier. From Messrs. Mitchell, Pittdown, came fine examples of Charles Margottin, Madame Margottin, Paul Neron, and Marquise de Mortemarte. In the class for twelve Roses of 1875 and 1876, Messrs. Paul & Sons were first with good blooms of Miss Hassard, Abel Carrière, Avocat Davivier, and remarkably well-coloured flowers of the dark crimson Sultan of Zanzibar. Mr. Turner showed in the same class Duchesse de Vallombrosa, Mrs. Baker, and Oxonian, in excellent condition. The best collection of Yellow Roses came from Messrs. Mitchell & Sons, and consisted of fine shapely blooms of Elise Sauvage, Adrienne Christophle, and Marie Van Houtte. In the amateurs' class the best blooms came from Mr. Davis, The Square, Wilton; these comprised good examples of Louis Van Houtte, Sir Garnet Wolseley, and Devoniensis. A good exhibition also came from Mr. Chard, Clarendon Park, Salisbury, who had Star of Waltham, Rubens, and Madame de St. Joseph. Mr. Ridout, gardener to T. B. Haywood, Esq., Woodbatch Lodge, Reigate, had beautiful examples of Abel Grand, Reynolds Hole (deep crimson), Marie Beauman, and La France. From Mr. Jowitt, Old Weir, Hereford, came good collections, in which were Belle Lyonnaise, exquisite blooms of Niphetos, the dark velvety Paul de Rohan, and the brilliant crimson Maréchal Vaillant. The best wedding bouquet was furnished by Mr. S. Moyses, Belgravia, but it appeared to us to be too large to be conveniently carried in the hand; it was composed chiefly of white Moss Rose buds, Gardenias, Tuberoses, double white Primulas, very small Jasmin-like Bouvardias, Ferns, and Grasses. Cut blooms of stove and greenhouse plants were sent in good condition by Mr. James Bolton, Combe Bank, Sevenoaks, and Mr. Bones, Havering Park, Essex; the former had excellent spikes of the scarlet Clerodendron fallax, Vinca oenolata, Ixora Williamsi, Brassia verrucosa, and remarkably large blossoms of a rich orange-salmon-coloured Begonia (B. Royalty) and Flamingo-plant (Anthurium Scherzerianum). On Mr. Bones' stand we noted fine blooms of Allamanda grandiflora, Pancratium speciosum, and mauve-coloured Bougainvillea; the best épergne, composed of Roses and Rose leaves only, came from Mr. Turner, of Slough. It consisted chiefly of Moss and Tea-scented kinds, all of which were highly and tastefully arranged. Mr. Soder had also a well arranged stand, but the blooms were of inferior quality; all the rest were much too heavy in appearance. Of table decorations, a report by Miss Hassard will be found in another column.

Miscellaneous Exhibitions.—Mr. Parker, Tooting, sent a collection of cut flowers of herbaceous plants, which was much admired; it contained blooms of Irises, the double-flowered variety of *Hesperis matronalis*, Larkspurs, and *Dietamnus Fraxinella*. The same exhibitor also showed stands of cut blooms of *Pæonias* in excellent condition; Mr. Cannell, Swanley, sent cut blooms of *Pelargoniums* in good condition; amongst them we noted trusses of the lovely salmon-coloured President MacMahon, and the rich, rosy-pink Lady Emily. *Verbenas* in variety were also shown by the same exhibitor, and they attracted much attention on account of their having unusually large, brilliantly-coloured pips. Mr. Burley, Brentwood, had also good stands of *Pelargoniums* of a meritorious character. From Mrs. Hodgkins, Hyde Grove, Manchester, came a collection of skeleton leaves and flowers, which were greatly admired.

Scottish Pansy Society's Show.—The thirty-third annual competition of this Society took place in Edinburgh on the 15th inst. The show was more successful than was anticipated, considering the backwardness of the spring. The flowers exhibited were, on the whole, remarkably fine and in great variety, and many of the exhibits were from comparatively distant localities. Of Pansies selected from any stand in the exhibition, Mr. William Paul had the best dark self, a mauve seedling, named Michael Saunders; best white self—Mr. Barr, with Princess Beatrice; best yellow self—Mr. Fleming, with Zama; best blue self—Messrs. Dickson & Co., with Sunnypark Rival; best white ground—Mr. Fleming, with Jeannie Fleming; best yellow ground—Mr. Ritchie, with Robert Burns; best flower in the room—Mr. Paul, with Michael Saunders. A first-class certificate was awarded to Mr. William Paul for three blooms of seedling white ground—Annie Wood Paul. A certificate of merit was also awarded to Mr. Todd, Newmilns, for one bloom of yellow ground Rev. J. T. Barton. A certificate of merit was likewise awarded to Mr. Paul for one bloom of mauve seedling Michael Saunders. The following were among the finest-named blooms:—Fancy Pansies—The Bride, James Grieve, James Taylor, J. B. Downie, Lizzie Cowan, Isa MacMeeking, Rev. H. Dombain, Miss Wallace, Mrs. Taylor, Buttercup, William Nimmo, M. Scott, Auntie Cuckoo, William Melville, Thomas Grainger, John Currie, F. W. Leland, W. Broadfoot, Kirbie, Adonis, Mrs. James Watt, James White, Portia, Miss McNutt, Countess of Strathmore, and Mrs. Birkmyre. Show Pansies—Jessie Foot, Robert Black, Jenny Anderson, Robert Burns, Bessie McAslan, Mrs. Arthur, Miss Hope, Annie W. Paul, Miss Rogers, May Queen, Michael Saunders, Mauve Queen, Sir Peter Coats, George Steedman, Princess Beatrice, Zama, Jeannie Fleming, Mrs. Fraser, Mrs. Horsburgh, D. McHutcheson, Royal Blue, Donald Sutherland, Ebor, John Waterston, Captain Knowles, Jeannie Grieve, Rev. J. T. Burton, and Sunnypark Rival.

QUESTIONS AND ANSWERS.

Cupressus Lawsoniana in flower.—I have a fine example of this charming Cypress completely laden with fruit, and a few weeks ago it was one mass of bloom, surpassing everything else in neatness. Is this at all uncommon? I. SHACKLETON. [The Lawson Cypress fruits abundantly, and seedlings have been raised in quantities from home-grown seeds.]

Destroying Plantains on Lawns (see p. 536).—Touch the crown of each Plantain with a small drop of sulphuric acid. In a few hours the Plantain will be destroyed, leaf and root. This mode is less tedious than grubbing, and it does not disturb the soil. Lawn sand, so far as my experience goes, kills everything it touches, except the roots of the Grass. After some weeks the Grass, therefore, comes again; but meanwhile the bare patches are a sad eyesore. If for some months the appearance of the lawn were given up, perhaps lawn sand might be useful. It seems to kill Daisies.—SCREBY.

Pickled Samphire.—Can you give me a good recipe for making this pickle? The plant (*Crithmum maritimum*) occurs plentifully upon the rocky coasts of South Wales, and is just now coming into bloom. I fancy that this ought to be the best time for collecting it, as its peculiar odour is now very strongly developed.—W. P. T.

Notice.—“F. W.,” “P. C.,” “A. W.,” “J. B.,” “H. C.,” and others are reminded that we never name plants or fruits unless the full address of the sender be given. The printed name of a plant or fruit can be of no interest to any but the person who sent it, and therefore we always reply by post upon receiving the address.

END OF VOL. XI.
